THIS handsomely got-up and lavishly illustrated volume is, the author informs us, a largely expanded transcript of a course of lectures delivered by him, in 1891 "in the Catholic University of America, at Washington, D.C." Its "main purpose is to give musicians and general readers an exact knowledge, based on experiment, of the principles of acoustics, and to present at the same time a brief exposition of the physical basis of musical harmony." A clear intimation is given at the outset (p. 18) of the predominant *rôle* which experiment is to play in the acoustical portion of the undertaking. Had Prof. Zahm not had at his disposal "all the more delicate and important instruments" of research and verification, in the theory of sound, constructed by Dr. Koenig of Paris, he would "not have attempted to give the present lectures on sound" before such an audience as that which actually attended them. With Dr. Koenig's apparatus around him, however, he had assured means of "entertaining" his hearers, and of "illustrating in a way that would otherwise be impossible the most salient facts and phenomena of sound." The late Isaac Todhunter has deprecated the systematic repetition of perfectly established experiments, on the ground that their results ought to be believed on the statements of a tutor—"probably a clergyman of mature knowledge, recognised ability, and blameless character"—to suspect whom was in itself irrational.[1] Prof. Zahm's practice pushes to a great length a view directly opposed to that enunciated—with obvious humorous exaggeration—by the well-known Cambridge private tutor. Not content with a single experiment decisive of each successive issue presented, he performs a whole series bringing into action all the resources of his superbly found collection of acoustical apparatus. It is no detraction from the clear and interesting manner in which these formidably numerous experiments are set forth, to say that the amount of space necessarily devoted to explaining the mechanism of the apparatus used gives to parts of Prof. Zahm's volume somewhat of the look of an acoustical instrument-maker's illustrated catalogue. Subject, however, to this defect, if defect it be, the lectures are decidedly pleasant and attractive reading. The illustrations, too, are thoroughly clear and beautifully executed, so that our author may be fairly congratulated on success in 'entertaining'—the word is his own—his hearers and readers. His object, to give to general readers an "exact knowledge" of the principles of acoustics, has also been in a fair measure attained, but subject to certain not inconsiderable deductions. In describing the processes and results of experiment Prof. Zahm is clear and thoroughgoing: in expounding the parts of acoustical theory which must be mastered if the facts thus obtained are to be understood in their mutual relations, he is often vague and superficial. Thus the nature of wave-motion, the formation of stationary undulations, the composition of small vibratory movements—matters of crucial importance to any connected comprehension of Acoustics—receive from him no effective elucidation. Nay, he is even chargeable with having, by the misuse of a technical term of perfectly settled meaning, written in a way likely to confuse his readers' ideas on these very matters. On p. 46 he calls certain points in a series of progressive waves "NODAL points where there is no motion," thus confusing two things which ought to be most carefully distinguished from each other, a point of *momentary* rest in a *progressive wave*, and one of *permanent* rest in a *stationary undulation*. The usage which restricts 'node' to this latter meaning is so well established that such use of it as the above is quite inexcusable, especially in an author who himself elsewhere, p. 146 &c., employs it in its ordinary signification. The same indifference to accuracy of expression recurs in this volume with a frequency not creditable to a professor of an exact science. Thus on p. 50 the return movement of a prong of a tuning fork is said to 'pull' air particles apart. On p. 52 we are told that the motions of particles of a water wave "are always at right angles to the direction of the wave itself." On p. 68 the author corrects this statement, but in doing so, takes occasion to speak of a plane "in," instead of 'passing through' the line of progression. On p. 380 he describes harmonic partial-tones as "modifying the quality of their fundamental," though he obviously means the quality of the compound sound due to the fundamental and other partial-tones combined. On p. 387 it is said that the "ratios of frequencies" which characterize particular sounds "are called intervals," and that by dividing one note by another we obtain the intervals between them. Language of this kind is, indeed, hardly misleading, but it is certainly very slipshod.

---

[1] "The Conflict of Studies," p. 17.

Before passing from the more generally acoustical, to the more specially musical portion of Prof. Zahm's volume, it is proper to point out one important respect in which it has the advantage over most, or possibly all, the manuals on the same subject which have preceded it. This merit consists in giving a somewhat full account of elaborate experimental researches on beats, combination-tones and quality conducted by Dr. Koenig, the results of which are to a considerable extent at variance with conclusions previously announced by Prof. Helmholtz. In the opinion of our author, Dr. Koenig is "one who, not excepting even the eminent German philosopher just mentioned (Helmholtz), has contributed more than any other person to the advancement of the science of acoustics" (p. 17). A more balanced judgment, while placing great reliance on Dr. Koenig's experimental skill and on the superlative excellence of the apparatus constructed by him, would probably attribute to Helmholtz's opinion a preponderant weight in interpreting and correlating the results of experiment. Be that, however, as it may, Prof. Zahm has done excellent service by popularizing the work so laboriously performed, and so modestly placed on record, by the eminent instrument-maker to whom no one who has put his hand to acoustical work can fail to be under considerable practical obligations.

The specifically musical are decidedly the least meritorious parts of our author's performance. The looseness of phraseology already complained of is here at its worst. On p. 166 we are told that a 'comma,' ($\frac{81}{80}$) is "the smallest interval used in music." A beginner might easily take this to mean that notes differing by only that interval were actually heard consecutively in a musical phrase—of course an absurd supposition. Very misleading, again, is the statement on p. 388 that tones, like major and minor tones, that differ from each other only by a comma "are considered in music to have the same value." The only rational meaning to be got out of it seems to be that *in the equally tempered scale* the distinction between major and minor tones is obliterated. On p. 389 the notes of the diatonic scale, and their relations, in respect to rapidity of vibration "to one another," are set out, and it is added that all but the second and the seventh of the intervals thus indicated are consonant. The essential piece of information, that it is not the intervals formed by these notes with "one another," but with *the tonic*, that are in question, is withheld, and so the reader is left free to suppose *e.g.* that the tritone, F—B, is a consonance. On p. 390 the 'inversion' of intervals is mentioned without any explanation of its meaning.

Attention may well be called to a process of reasoning which occurs on pp. 388–390. Prof. Zahm abruptly introduces (p. 388) calculation by "frequency-ratios"; assumes, without attempt at proof, that addition of two semitones is performed by squaring the ratio $\frac{16}{15}$, and then remarks (p. 390) "From the foregoing we observe that the sum of two intervals is obtained by multiplying, not by adding their ratios together." An *assumption* in a *particular case* is thus made to do duty as a *general demonstration.*

On p. 396 we read that "so perfectly does the interval of the fifth answer the requirements of the ear that even unpractised singers find it quite natural to take a fifth to a chorus that does not quite suit the pitch of their voice." If, as this passage appears to suggest, practised singers in America find it still more natural to accompany melodies in consecutive fifths, wonderful effects may surely be expected from the choruses to be heard at the Chicago exhibition.

On p. 429 our author describes a diagram by Helmholtz as concerned with the transposition of an interval by an octave, whereas what it really deals with is the enlargement of the interval in question by the addition to it of an octave. On p. 430 he writes down, *as constituents of the chromatic scale of C,* the notes E♯, F♭, B♯ and C♭.

On p. 441, he tells us that in listening to such violin players as Joachim, Wilhelmj, and others "one can always hear distinctly the *Tartini*, or beat-tones, that add such richness and volume to violin music."

To gauge the amount of truth contained in this remark it suffices to bear in mind that in the case of most major, and of all minor consonant chords, Tartini's tones cause a *decided dissonance.* Players who made them 'always distinctly audible' would soon be reduced to permanent inaudibility themselves.

Prof. Zahm's volume is creditably free from misprints: the following have, however, been noted:

P. 23, l. 16 'period' for 'periods.'
P. 68, l. 21 'amplitude' for 'amplitudes.'
P. 90, l. 8 'Ajugari' for 'Agujari.'
P. 142, in diagram, B_4♯ for B_4.
P. 152, in diagram I, B♯ for B.
P. 388, ll. 11 and 12, G for F.

GERLAND'S ETHNOLOGICAL ATLAS.

Atlas der Völkerkunde. (Berghaus' Physikalischer Atlas, Abth. vii.). Bearbeitet von Dr. Georg Gerland, Professor a.d. Universität in Strassburg. (Gotha: Perthes, 1892.)

ANTHROPOLOGY owes much to Prof. Gerland, whose completion of the two last volumes of the late Prof. Waitz's "Anthropologie der Naturvölker" is a monument of that co-ordinated knowledge of fact which is the source of sound principle. His new "Atlas of Ethnology," while forming part of the great Physical Atlas of Berghaus, may be obtained and used as a separate work by anthropologists, to whom it will be of great service in methodizing the vast and growing information with which they have to deal. This application of graphical method, it is true, has difficulties which even the greatest skill cannot altogether overcome, but Prof. Gerland may well be content with his success in making evident at a glance the characteristics of mankind, seen from many points of view. Their distribution over the earth, as thus made evident, may often lead straight on into theories of origin. The fifteen plates contain nearly fifty maps, each suggesting a principle, or showing where there is room for one.

Plate I. represents on two planiglobes the classification of human races as to skin and hair. Prof. Gerland does not even combine these two characteristics, and points out in his introductory remarks that any attempt to map out man into defined physical races is impossible, for such division does not exist in nature. Anthropologists of course know this, but care is not always taken to make it clear that race-types are not so much complete realities as statistical abstractions from partial realities, the various measurable characters of skull, limbs, complexion, hair-form, &c., combining and blending too intricately for absolute definition. I was struck by meeting lately in a popular book with a confident mention of the four distinct Aryan race-types, and it occurred to me that it would bring the statement down to its bearings to put one of Prof. Gerland's planiglobes before the author, desiring him to define and map out these varieties of mankind. Even in Gerland's broad general distinctions of complexion and hair, an anthropologist not thoroughly special on the anatomical side may find novelty and difficulty. The opinion that all native Americans are similar as to race is here strongly and probably with reason modified by the native Brazilians being separated on the complexion-map from other peoples of North and South America, and placed to match the Tartars and Chinese. What amount of evidence there is for placing the Berbers of North Africa under the same map-colour seems not so clear, but it is to be noticed that the same tint includes several more or less distinct grades in Broca's scale. An attempt is even made to separate the friz-haired negroids into classes according to the arrangement of their corkscrew-tufts of hair on the skin. Plate III., in two maps, classifies man according to his religious beliefs and customs, and here the prevalence of special rites offers instructive generalizations. Thus the American line which limits the smoking of tobacco as a religious ceremony, indicates the spread of this peculiar rite from some religious centre over an enormous area. No doubt it is rooted in nature, from the fact that its narcotic ecstasy brought the priest into direct visionary contact with the spirit-world. But none the less, it proves the religions of savage tribes, separated by great distances on the map, to be bound together by historical connexion. Not less remarkable is the compactness of the districts of Eastern Asia and the opposite Continent of America, where masks are used, apparently originally with religious significance Here again it is evident that we have to do not merely with independent growth from the human mind, but in some way with historical transmission. It must be remembered in using these maps, that they bind their author only to fact, and not to theoretical interpretation. This same plate maps out the immense districts whose natives have a myth of a deluge, the upheaving of the earth, &c., but it cannot distinguish in North and South America, for instance, between regions where deluge-myths are old, and those where they were introduced by the Jesuits a few generations ago. Plate IV., mapping out regions liable to special diseases, as malarious fevers, pestilence, cholera, yaws, &c., contains in a condensed form a vast collection of knowledge, bearing on anthropological arguments as to the relation of race to physical constitution, and thus opening into one of the great problems of the history of man. Plate V. classes out the varieties of human food, clothing, dwellings and occupations. Plate VI. and onward map out the distribution of nations and tribes at different periods as known to history, Plate XIV. being devoted to the distribution of languages over the world.

Anthropologists who keep this atlas at hand as a help in their work will by practice find out its merits and defects. The representation of the geographical distribution of arts and customs has long been a feature of the Pitt-Rivers Museum, where so far as possible each series, illustrating development and transmission of culture, is accompanied by a small world-map coloured to show the parts of the world it occupies. It is of course impossible to Prof. Gerland to work in such detail, involving as it would do hundreds of separate charts. He has to indicate his distributions on a moderate number of plates and mostly uses planiglobes, a projection which, after being neglected for generations, will, in its improved modern arrangement, certainly come into more general favour. On these, by ingenious devices of tinted patches and streaks, combined with lines and dots, he succeeds in giving a more general survey of man and civilization than our students have ever had in their hands before. EDWARD B. TYLOR.

OUR BOOK SHELF.

Castorologia; or, The History and Traditions of the Canadian Beaver. By Horace Martin, F.Z.S. (London: Stanford, 1892.)

"BEAVER" was once the most important fur in the world. In former days the pelt of this Rodent was the standard by which all barter in the Dominion of Canada was regulated, and "beaver" passed as current coin throughout the whole of North America. Even now the quantity of beaver skins brought to England is considerable. Mr. Poland, in his "Fur-bearing Animals," tells us that upwards of 63,000 beaver skins were sold by the Hudson's Bay Company in 1891. But "beaver-hats" formerly required a much larger supply than this, and in 1743 it is said that 127,000 beaver-skins were imported into La Rochelle alone. Our "top" hats are now made of silk, and beaver has become a fur of second-rate importance.

Besides the fur of the beaver many other points of interest attached to this animal will be found discussed more or less completely in Mr. Martin's volume. Long before its fur was required for hats *castoreum* or castorin—a substance found in two large glands, situated near the base of the beaver's tail—was a much-valued specific in medicine, as spoken of by Hippocrates and Pliny. Even at the present time its use is by no means abandoned, and the "crude article" is "still sold at our drug-stores" at prices varying "from eight to ten dollars a pound." But in past centuries castoreum was considered a sovereign remedy for every kind of disease. Many amusing details on this part of the subject are given by Mr. Martin, mostly extracted from the "Castorologia" of Johannes Francus, published in 1685. The wisdom of Solomon himself is attributed by this learned author to the virtues of the beaver. To acquire it, it is only necessary "to wear a hat of beaver's skin, to rub the head and spine with that animal's oil, and to take twice a year the weight of a gold crown piece of castoreum."

At the end of his volume Mr. Martin places a short account by Mr. C. V. Riley, the well-known American entomologist, of *Platypsillus castoris*, a parasite on the beaver, and one of the most remarkable among the many extraordinary forms of parasitic insects. Mr. Riley correctly refers this creature to the coleoptera, although other naturalists, and, amongst others, its discoverer, Ritsema, have expressed different views on this point He omits, however, to refer to the excellent account of *Platypsillus castoris*, written by the late John Leconte, and published in the Proceedings of the Zoological Society of London for 1872. Dr. Leconte has here shown that it is necessary to make a special family (Platypsillidæ) for the reception of this curious parasite, but that it must be unquestionably referred to the coleoptera.

On account of these and other peculiarities the beaver is unquestionably an animal of great general interest, and Mr. Martin has done well to devote a volume to what is evidently his favourite theme. There is, we must allow, little, if anything, original in it, and the statements on scientific points cannot always be implicitly depended upon. But the author has brought together a large amount of information on the subject, and his book is "popularly written" and "fully illustrated," though we cannot quite agree to his claims to have produced an "exhaustive monograph."

An Atlas of Astronomy. By Sir Robert Stawell Ball, LL.D., F.R.S. (London: George Philip and Son, 1892.)

A new book by Sir Robert Ball is always a matter of interest, but the present one naturally lacks the usual characteristics. It is described as "a series of 72 plates with introduction and index." In addition to monthly and general maps of the stars, the atlas reproduces pictures of the sun, moon, planets, and comets, and contains diagrams illustrating their motions and dimensions. As the book is chiefly meant to be a companion to more general works, the introductory matter is purposely brief, but still it has several features of interest. Special attention may be drawn to the excellent description of a simple graphical method of determining the orbit of a binary star.

To the serious student who may possess a small telescope the new atlas will be very useful. Here he may learn how to determine the positions of sun spots, how to find the places occupied by the various planets, and what objects are most likely to be within reach of his instrument. Those interested in selenography will derive much assistance from the twelve plates showing the moon at different phases, which have been specially drawn by Mr. Eger, each being accompanied by an index map. One can only wonder, however, that some of the recent excellent photographs of the moon have not been pressed into the service.

The star maps, on the whole, are excellent, and our only complaint is of the excessive density of the Milky Way, which, in some parts of the maps, is almost sufficient to obliterate the names and numbers of the stars. The monthly maps will be particularly useful to those who are just learning the constellations, a new feature being a belt indicating the track of the planets.

Spectroscopic astronomy is entirely omitted, the author being of opinion that this great branch of work can only receive justice in a separate atlas. In this we heartily agree, and trust that such an atlas will soon be forthcoming.

The author's large following of readers will no doubt welcome the new comer, but we must express regret that astronomical photographs are not more fully represented. It would be interesting, for example, to reproduce a series of photographs of typical nebulæ, all of which, we believe, are now available. A plate showing the advantages of photography in the delineation of stars would also add to the interest of the atlas.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Vector Analysis.

I fancied that, in reply to the voluminous letters of Prof. Willard Gibbs (Nature, xliii. 511; xliv. 79), I had said in a few words all that is requisite (if, indeed anything *be* requisite) to show the necessary impotence, as well as the inevitable unwieldiness, of every system of (so-called) *Vector Analysis* which does not recognize as its most important feature the product (or the quotient) of two vectors:—*i.e.* a Quaternion.

A recent perusal of the first four pages of a memoir by Mr. O. Heaviside (*Phil. Trans.* 1892):—for so far only could I go:—has dispelled the illusion. For he calls the correspondence just spoken of a "rather one-sided discussion":—a truly Delphic delivery:—cleared up, however, by what follows it. I particularly desired to read the memoir (which the Author had kindly sent me) as I hoped to learn from it something new in Electrodynamics. But, on the fifth page, I met the check-taker as it were:—and found that I must pay before I could go further. I found that I should not only have to unlearn Quaternions (in whose disfavour much is said) but also to learn a new and most uncouth parody of notations long familiar to me; so I had to relinquish the attempt. In the last of the four pages of my progress, I had found that Mr. Heaviside (though, as above stated, he has a system of his own) is an admirer of Prof. Gibbs' system, to such an extent at least that he thinks "his treatment of the linear vector operator specially deserving of notice." There I was content to leave the matter.

But Mr. Heaviside has just published (*Electrician*, 9/12/92) an elaborate attack on Quaternions, of a kind which is calculated to do real injury to beginners. In answer to his remarks, in which he continues to point to me as the persistent advocate of a system which all right-minded physicists should avoid, I would simply refer him (and his readers, if there be such) to a brief Address which I gave a short time ago to the Physical Society of Edinburgh University (*Phil. Mag.* Jan. 1890). One or two sentences, alone, I will quote here:—

> "if we can find a language which secures, to an unparalleled extent, compactness and elegance, and at the same time is transcendently expressive—bearing its full meaning on its face—it is surely foolish, at least, not to make habitual use of it."
>
> "For (Hamilton) the most complex trains of formulæ, of the most artificial kind, had no secrets:—he was one of the very few who could afford to dispense with simplifications: yet, when he had tried quaternions, he threw over all other methods in their favour, devoting almost exclusively to their development the last twenty years of an exceedingly active life."

The main object, however, of my present letter, is to call attention to a paper by Dr. Knott, recently read before the Royal Society of Edinburgh. Dr. Knott has actually had the courage to *read* the pamphlets of Gibbs and Heaviside; and, after an arduous journey through these trackless jungles, has emerged a more resolute supporter of Quaternions than when he entered. He has revealed the (from me at least) hitherto hidden mysteries of the Dyadic, and of Prof. Gibbs' strange symbols Pot, Lap, Max, New, &c. The first turns out to be only the linear and vector function; and the others are merely more or less distressing symptoms characteristic of imperfect digestion or assimilation of ∇. And when, at my request, Dr. Knott translated into intelligible form the various terms of one of the less formidable formulæ of Mr. Heaviside's memoir, I was surprized to find two old and very unpretending friends masquerading in one person like a pantomime Blunderbore. In one of his Avatars the monster contains, besides the enclosing brackets, no fewer than 24 letters, 12 suffixes, 3 points, and 5 signs! When he next appears he has still the brackets to hold him together, but although he has now only 18 letters, he makes up his full tale of 44 (or 46) symbols; for he has 9 suffixes, 3 indices, 3 points, 5 signs, and 3 *pairs* of parentheses! I used to know him as compounded of 14 separate marks only, viz.:— $V^2\nabla\sigma + 2S\nabla\nabla_1 S\sigma\sigma_1$:—but, unless I had required to dissect him, I should never have put him in anything resembling his new guise.

Dr. Knott's paper is, throughout, interesting and instructive:—it is a complete exposure of the pretensions and defects of the (so-called) Vector Systems. "Wer diesen Schleier hebt soll Wahrheit schauen!" I find it difficult to decide whether the impression its revelations have left on me is that of mere amused disappointment, or of mingled astonishment and pity.

P. G. TAIT.

Edinburgh, 24/12/92.

Measurement of Distances of Binary Stars.

WITH reference to Mr. C. E. Stromeyer's letter on the above subject, which appeared on p. 199, it may be of interest to point out that his plan of determining the distance of a binary star is by no means a new one.

The method was, I think, first suggested by Mr. Fox Talbot at the Edinburgh meeting of the British Association in 1871; but the mere idea was sufficiently obvious as soon as the possibility of determining velocities by the spectroscope had been demonstrated by Dr. Huggins.

The first discussion of the geometrical conditions of the problem was given by Prof. C. Niven in the *Monthly Notices*, vol. xxxiv. No. 7, where he exhibits the relation connecting the parallax, the relative velocity, and the elements of the orbit of a double star, and computes the value of the product (πV) of the parallax and velocity for a small number of binary systems.

In a paper published in the Proceedings of the Royal Irish Academy for May, 1886, I examined the same question from a slightly different point of view, being at the time unaware of Prof. Niven's paper, and was led to similar results. An epitome of this paper was published in your Astronomical Column, vol. xxxiv. p. 206. From the results obtained it appeared that, all things considered, γ-Coronæ Australis and α-Centauri were the most likely binaries to yield to this method of eliciting the secret of their parallax, while α-Geminorum, one of the stars selected by Mr. Stromeyer, was shown to be most unfavourable on account of the situation of its orbit.

In the *Monthly Notices* for March, 1890, I again drew attention to the subject in view of the accuracy of the results obtained by the photographic method in the hands of Prof. Pickering and Prof. Vogel. In this paper I gave an extended list of binaries with the usual geometrical and dynamical elements, and in addition the two elements A and B on which the relative velocity depends. I also gave the greatest value which πV can attain in each case and the velocity to be expected in the case of those stars whose parallaxes had been determined.

Again in Mr. J. E. Gore's valuable catalogue of Binary Star Orbits, published in the Proceedings of the Royal Irish Academy for June, 1890, columns 18 and 19 are devoted to the constants A and B computed from my formulæ (which I may say ought more properly to be called Prof. Niven's formulæ on account of the priority of his paper) for eighty-one different orbits.

The subject has also been discussed by Miss Clerke in "The System of the Stars," pp. 199–201, where references to most of the original publications will be found.

I may perhaps add that the inverse problem of determining the elements of the orbit from spectroscopic observations alone has also been investigated by me in the *Monthly Notices*, vol. li. No. 5, where I have deduced the principal elements of the orbit of β-Aurigæ, a spectroscopic double which no telescope can divide.

I have been disappointed that astronomers engaged on spectroscopic determinations of stellar velocities have not devoted more attention to observations of already known binaries, which appear to me to offer a promising field of work, and have often regretted that at this observatory we have not the means of undertaking the investigation, and if Mr. Stromeyer's letter has no other effect than to bring the subject once more forward it will have done good service, but I should like to point out that the second of the stars selected by him ought on no account to be taken as a test of the feasibility of the method, since the accurate discussion of the conditions shows that unless this is an exceptionally remote system the velocity must be very small indeed. For instance, assuming Johnson's parallax, viz. 0″·20, the relative velocity of the components amounted last year to only 0·6 miles per second.

In the northern hemisphere the most favourably situated binaries are 70 Ophiuchi, ξ-Ursæ Majoris, and, if Peters' orbit represents the real motion of the pair, 61 Cygni; while for the southern hemisphere special attention ought to be directed to α-Centauri and γ-Coronæ Australis.

In Mr. Gore's Catalogue, referred to above, will be found all the materials for determining when to observe any known binary most favourably in this respect, and for deducing its parallax from the measures obtained, and it ought to be borne in mind before letting the subject sink back once more into oblivion, that, other things being equal, this method is most likely to succeed in the case of the most distant systems, where the parallax is so small that the ordinary trigonometrical method necessarily fails us, and that when the micrometer, the heliometer, and the stellar photograph break down, the spectroscope will sound the further depths with ever-increasing facility.

Dunsink Observatory, co. Dublin. ARTHUR A. RAMBAUT.
December 30.

December Meteors (Geminids).

THESE meteors were moderately abundant on the night of December 12, which appears to have been a very favourable one in regard to weather. The chief radiant point was observed in the normal position very close to α Geminorum, and there was a strong contemporary shower from a centre east of β Geminorum.

At 10h. 10m. December 12, a fireball estimated to be twice as brilliant as Venus was observed by Mr. Booth at Leeds. It moved rather slowly from 150° + 43° to 188° + 41°, and divided into two pieces at the finish.

Mr. Wm. Burrows, of Small Lane, Ormskirk, writes to me with reference to a meteorite which he observed to fall at a later hour on the same night. He says the time was 6.52 a.m. (December 13), and refers to the phenomenon as follows:—"Seeing the meteor was coming to the earth I crossed the road to where it appeared to be falling, and it fell about two yards from me. When it struck the earth it made a noise like the report of a gun; it also went black instantly. While descending it had a tail of fire about a foot long. It is $1\frac{3}{8}$ inch in diameter one way, and $1\frac{1}{4}$ inch another, and one inch thick."

Mr. Burrows sends drawings of the object, and it being still in his possession it is hoped the matter may be suitably investigated. Should it prove a veritable meteorite one interesting circumstance in connection with it will be that its descent took place concurrently with the shower of Geminids.

It is significant that December 9–13 constitutes a well-defined ærolitic epoch, rendered memorable by the fall at Wold Cottage, Thwing, Yorkshire, on December 13, 1795, and by many others, such as that at Mässing, Bavaria, December 13, 1803, at Weston, Connecticut, U.S.A., December 14, 1807; at Wiborg, Finland, December 13, 1813; at Ausson, France, December 9, 1858; at Baudong, Java, December 10, 1871, &c.

Bristol, January 1. W. F. DENNING.

The Earth's Age.

AS Dr. Wallace (NATURE, p. 175) trusts "that on further consideration" I shall "admit that" my "objection is invalid," it is evident that I have failed to make clear to him my argument showing that his data do not warrant his conclusion.

He overlooks the fact that a thickness of 177,200 feet of sedimentary rocks is, standing alone, a perfectly indefinite quantity; to make it definite it must have a definite area.

As he mentions no area for it we are justified in assuming that he means the land area of the globe, whereas his calculation is made as though area were not of the essence of the problem, in short, as if the formation of a pile of sediment 177,200 feet thick, of no matter what area, were the problem.

In Sir A. Geikie's calculation and all other similar ones with which I am acquainted, the thickness of the sedimentary rocks is tacitly assumed to be their thickness all over the land area of the globe.

Dr. Wallace's calculation leads to the absurd result that continents are growing nineteen times as fast as materials are produced to supply their growth.

Leaving the question of the conclusions to which Dr. Wallace's data logically lead, I may say that I am not responsible, and do not hold him to be responsible, for the absurd theory as to the thickness of sedimentary rocks on which they are based.

In order to arrive at a scientifically accurate result, what we require to know is the present actual thickness in every part of the world, plus all the thickness which has previously existed in, but since been denuded away from, every area. The existing thickness in geologically explored areas can perhaps be ascertained within certain limits of error from geological maps and memoirs. For instance where the surface consists of Torridon Sandstone overlying Archæan gneiss of igneous origin, the thickness of sedimentary rock is that of the Torridon Sandstone only, if we assume that the gneiss there is part of the metamorphosed original crust of the earth, for the existence of which Rosenbusch has recently argued.

It is easily demonstrable, first, that in many places the existing thickness of each formation, where undenuded, is far from being the maximum thickness, and, secondly, from the thinning out in some directions, or merging, near the old shoreline, into conglomerates, that some formations were never deposited over certain areas; indeed, the very existence of a sedimentary deposit necessarily implies that of land undergoing denudation and not receiving deposit, although it may well be doubted whether the land area was always nineteen times the area receiving deposit.

Reasoning from the deposits preserved as to those removed by denudation, it is highly improbable that any considerable area ever received either the complete series of deposits, or on the average anything like the maximum thickness of the deposits it actually received. In addition to this, some formations usually considered to be successive may be really contemporaneous, so that the figures representing maximum thicknesses usually taken in calculating the earth's age are probably far above the truth for the purpose in question.

The immense labour involved in calculating the existing thickness of sedimentary rocks in each area, and the thickness which there is any reasonable ground for supposing to have been at any time denuded from that area, as well as the uncertainty of the results, has probably deterred geologists from attempting the task, especially as large areas are very imperfectly known.

BERNARD HOBSON.

Tapton Elms, Sheffield, December 24.

THE first part of Mr. Hobson's letter alone requires notice from me, as the latter part characterizes as absurd the views of those eminent geologists who have estimated the total thickness of the sedimentary rocks, and seems to assume that such writers as the late Dr. Croll and Sir Andrew Ramsay overlooked the very obvious considerations he sets forth.

As regards myself, he reiterates the statement that when geologists have estimated the total thickness of the sedimentary rocks at 177,200 feet, they mean that this amount of sediment has covered the whole land surface of the globe; that, for example, the coal measures, the lias, the chalk, the greensand, the London clay, &c., &c., were each deposited over the whole of the continents, since it is by adding together the thicknesses of these and all other strata that the figure 177,200 feet (equal to 33 miles) has been obtained.

Mr. Hobson concludes with what he seems to think is a *reductio ad absurdum*:—"Dr. Wallace's calculation leads to the absurd result that continents are growing nineteen times as fast as materials are produced to supply their growth."

But the apparent absurdity arises from the absence of any definition of the "growth of continents," and also from supposing that the growth of continents is the problem under discussion. The question is, as to the growth in thickness, of sedimentary deposits such as those which form the geological series. These deposits are each laid down on an area very much smaller than the whole surface of the continent from the denudation of which they are formed. They are therefore necessarily very much thicker than the average thickness of the denuded layer, and the ratio of the area of denudation to the area of deposition, which I have estimated at 19 to 1, gives their proportionate thickness. If Mr. Hobson still maintains that he is right, he can only prove it by adducing *evidence* that every component of the series of sedimentary rocks has once covered the whole land-surface of the globe; not by assuming that it has done so, and characterizing the teaching of all geologists to the contrary as absurd.

ALFRED R. WALLACE.

Ancient Ice Ages.

MR. READE in his letter (NATURE, p. 174) refers to the striations on the pebbles forming the conglomerates at Abberley and the Clent Hills.

Following the late Sir Andrew Ramsay, he considers the deposits to be of glacial origin, but goes further than that distinguished geologist in citing them as proof of a former ice age.

It is but reasonable to suppose that *glaciers* existed in past ages in places where the conditions—such as high altitude and abundant precipitation—were favourable.

Before, however, the existence of a former *glacial period* can be established, we must have evidence of contemporaneous deposits of undoubtedly glacial origin, and extending over widespread areas—say half a hemisphere.

Printing Mathematics.

THE use of the solidus in printing fractions has been advocated by authorities of such weight that it seems almost a heresy to call it into question. Yet I venture to think that there is a good deal to be said against it. In such matters the course preferred by mathematical writers and their printers is apt to take precedence over that which is most convenient for the great body of those who will read their work. It is tacitly assumed by those who prefer this notation that the getting of mathematical formulæ into line with ordinary printing is an unmixed advantage. No doubt it is easier to set up the work in type thus, but with the consequent rapidity and cheapness of printing the advantage ends. Most people will agree that it is much pleasanter to read a mathematical book in which the letterpress is well spaced, so that the formulæ stand out clearly from the explanatory language, than one in which the two run together in an unbroken stream: just as a book divided into paragraphs is more readable than one which is not. The old style is more restful to the mind and eye, and one can more readily pick out the salient features of the demonstration.

Another aspect of the question seems to me more important. In making any calculation mentally it is much easier to visualize fractions, more especially if complicated, as written in the ordinary way than as written with the new-fashioned notation. The component parts of the mental picture are imagined as spread over a plane instead of being arranged along a line, and can be thought of separately with less confusion. From a similar point of view it will be admitted that it is inconvenient to write mathematical expressions in one form and to print them in another.

Then, again, I doubt whether the assumption that the solidus notation conduces to accuracy is justified. No doubt the printer makes fewer original errors; but whereas with the old notation his frequent glaring errors are more readily detected by the proof-reader (or, if missed by him, by the ordinary reader), with the new notation the misplacement or omission of a solidus is, from the simplicity of the error, likely to be overlooked. In general, no one will be the poorer if a little more trouble is taken with the printing, and a little more paper is used for the book.

The symbol / has advantages over its equivalent ÷, and to its restricted use, such as is made by Sir G. Stokes, one can hardly object; it matters little how such expressions as a/b or dy/dx are printed. But it is the thin end of the wedge; and one is under a debt of gratitude to Mr. Cassie for showing, in your issue of November 3, to what it may lead. May it be a long time before we have to learn to substitute for the harmless expression, $\frac{b^{\frac{1}{2}}}{c(d+e)^3}$ its newest equivalent, $| b \diagdown 1 / 2 | / c \mid d + e \diagdown 3 |$! I trust that no one will interpret the final note of exclamation as a factorial symbol.

M. J. JACKSON.

D. I. Sind College, Karachi, November 23.

The Teaching of Botany.

I DO not think there is at present any book in English giving practical instructions for experiments in Physiological Botany. There is, however, an excellent book of this kind in German, Dr. W. Detmer's "Das pflanzen-physiologische Praktikum," published by Gustav Fischer, Jena, 1888. This, no doubt, contains all that your correspondent "A. H." (NATURE, *ante*, p. 151) requires, though it is perhaps somewhat more advanced than is necessary for school teaching. D. H. SCOTT.

Old Palace, Richmond, Surrey.

THE ORIGIN OF THE YEAR.[1]

IV.

THE reformation of the Egyptian calendar, to be gathered, as I suggested in my last article, from the decree of Tanis, is not, however, the point to which reference is generally made in connection with the decree. The attempt recorded by it to get rid of the vague year is generally dwelt on.

Although the system of reckoning which was based on the vague year had advantages with which it has not been sufficiently credited, undoubtedly it had its drawbacks.

The tetramenes, with their special symbolism of flood, seed, and harvest time, had apparently all meant each in turn; however, the meanings of the signs were changed, the "winter season" occurred in this way in the height of summer, the "sowing time" when the whole land was inundated, and there was no land to plant, and so on. Each festival, too, swept through the year. Still, it is quite certain that information was given by the priests each year in advance, so that agriculture did not suffer; for if this had not been done, the system, instead of dying hard, as it did, would have been abolished thousands of years before.

Before I proceed to state shortly what happened with regard to the fixing of the year, it will be convenient here to state a suggestion that has occurred to me, on astronomical grounds, with regard to the initial change of gn.

It is to be noted that in the old tables of the months, instead of Sirius leading the year, we have Teχi with the two eathers of Amen. In later times this is changed to Sirius.

I believe it is generally acknowledged that the month tables at the Ramesseum is the oldest one we have; there is a variant at Edfu. They both run as follows, and no doubt they had their origin when a 1st Thoth coincided with an heliacal rising and Nile flood.

Egyptian month.	Tropical month.	Ramesseum.	Edfu.
Thoth	June–July	Teχi	Teχ
Phaophi	July–Aug.	Ptah (Ptah-res-aneb-f)	Ptah (Menχ)
Athyr	Aug.–Sep.	Hathor	?
Choiak	Sep.–Oct.	Paχt	Kehek
Tybi	Oct.–Nov.	Min	Set-but
Mechir	Nov.–Dec.	Jackal (reḳḥ-ur)	Hippopotamus (reḳḥur)
Phamenoth	Dec.–Jan.	,, (reḳḥ-netches)	Hippopotamus (reḳḥ-netches)
Pharmuthi	Jan.–Feb.	Rennuti	Renen
Pachon	Feb.–Mar.	χensu	χensu
Payni	Mar.–Ap.	Horus (χonti)	Horus (Hor-χent-χati)
Epiphi	Ap.–May	Åpet	Åpet
Mesori	May–June	Horus (Hor-m-χut)	Horus (Hor-ra-m-χut)

I am informed that Teχi, in the above month-list, has some relation to Thoth. In the early month-list the goddess is represented with the two feathers of Amen, and in this early stage I fancy we can recognize her as Amen-t; but in later copies of the table the symbol is changed to that of *Sirius*. This, then, looks like a change of cult depending upon the introduction of a new star—that is, a star indicating by its heliacal rising the Nile rise after the one first used had become useless for such a purpose.

I have said that the Ramesseum month list is probably the oldest one we have. It is considered by some to date only from Ramses II., and to indicate a fixed year; such, however, is not Krall's opinion.[1] He writes:—

"The latest investigations of Dümichen show that the calendar of Medinet-Abu is only a copy of the original composed under Ramses II. about 120 years before. . . .

"But the true original of the calendar of Medinet-Abu does not even date from the time of Ramses II. It is known to every Egyptologist how little the time of the Ramessids produced what was truly original, how much just this time restricted itself to a reproduction of the traditions of previous generations. In the calendar of Medinet-Abu we have (p. 48) not a fixed year instituted under Ramses II., but the normal year of the old time, the vague year, as it was, to use Dschewhari's words quoted above (p. 852), in the first year of its institution, the year as it was before the Egyptians had made two unwelcome observations: First, that the year of 365 days did not correspond to the reality, but shifted by one day in four years with regard to the seasons; secondly—which of course took a much longer time—that the rising of Sirius ceased to coincide with the beginning of the Nile flood.

"We are led to the same conclusion by a consideration of the festivals given in the calendar of Medinet-Abu. They are almost without exception the festivals which we have found in our previous investigation of the calendars of Esne and Edfu to be attached to the same days. We know already the Uaya festival of the 17th and 18th Thoth, the festival of Hermes of the 19th Thoth, the great feast of Amen beginning on the 19th Paophi, the Osiris festivals of the last decade of Choiak, and that of the coronation of Horus on the 1st Tybi.

"Festivals somehow differing from the ancient traditions, and general usage are unknown in the calendar of Medinet-Abu, and it is just such festivals which have enabled us to trace fixed years in the calendars of Edfu and Esne.

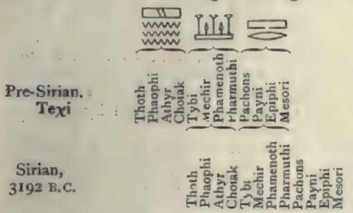
"We are as little justified in considering the mythologico-astronomical representations and inscriptions on the graves of the time of the Ramessids as founded on a fixed year, as we can do this in the case of the Medinet-Abu calendar. In this the astronomical element of the calendar is quite overgrown by the mythological. Not only was the daily and yearly course of the sun a most important event for the Egyptian astronomer, but the priest also had in his sacred books many mythological records concerning the god Rā, which had to be taken into account in these representations. The mythological ideas dated from the oldest periods of Egyptian history; we shall, therefore, be obliged for their explanation not to remain in the 13th or 14th century before Christ, but to ascend into previous centuries; *I should think about the middle of the fourth millennium before Christ, that is the time at which the true original of the Medinet-Abu calendar was framed.* Further we must in these mythological and astronomical representations not overlook the fact that we cannot expect them to show mathematical accuracy—that, on the contrary, if that is a consideration, we must proceed with the greatest caution. We know now how inexact were the representations and texts of tombs, especially where the Egyptian artist could suppose that no human eye would inspect his work; we also know how often representations stop short for want of room, and how much the contents were mutilated for the sake of symmetry."

---

[1] Continued from p. 35.

[1] *Op. cit.* p. 48.

There is also, as I have indicated, temple evidence that Sirius was not the first star utilized as a herald of sunrise. We have then this possibility to explain the variation from the true meaning of the signs in Ramessid times.



And it may be gathered from this that the Calendar was reorganized[1] when the Sirius worship came in and that the change effected in 619 B.C. brought the hieroglyphic signs back to their natural meaning and first use.

Before I pass on it may be convenient in connection with the above month-tables to refer in the briefest way to the mythology relating to the yearly movement of the sun, in order to show that when this question is considered at all, if it helps us with regard to the mythology connected with the rising and setting of stars, it will as assuredly help us with regard to the mythology of the various changes which occur throughout the year.

We have, as we have seen, in the Egyptian year really the prototype of our own. The Egyptians, thousands of years ago, had an almost perfect year containing twelve months, but instead of four seasons they had three, the time of the sowing, the time of the harvest, and the time of the inundation. Unfortunately, at various times in Egyptian history, the symbols for the tetramenes seem to have got changed.

The above-given inscriptions show that they had a distinct symbolism for each of the months. Gods or goddesses are given for ten months out of the twelve, and where we have not these, we have the hippopotamus (or the pig) and the jackal, two circumpolar constellations. I think there is no question that we are dealing here with these constellations, though the figures have been supposed to represent something quite different.

There are also myths and symbols of the twelve changes during the twelve hours of the day; the sun being figured as a child at rising, as an old man when setting in the evening. These ideas were also transferred to the annual motion of the sun. In Macrobius, as quoted by Krall, we find the statement that the Egyptians compared the yearly course of the sun also with the phases of human life.

Little child = Winter solstice.
Young man = Spring equinox.
Bearded man = Summer solstice.
Old man = Autumnal equinox.

With the day of the summer solstice the sun reaches the greatest northern rising amplitude, and at the winter solstice its greatest southern amplitude. By the solstices the year is divided into two approximately equal parts; during the one the points of rising move southwards, during the other northwards.

This phenomenon, it is stated, was symbolized by the two eyes of Rā, the so-called Utchats, which look in different directions. They appear as representing the sun in the two halves of the year.

We have next to discuss the fixed year, to which the Egyptian chronologists were finally driven in later Egyptian times.

The decree of Tanis was the true precursor of the Julian correction of the calendar. In consequence of this correction *we* now add a day every four years to the end of February. The decree regulated the addition, by the Egyptians, of a day every four years by adding a day to the epacts, which were thus 6 every four years instead of being always 5 as they had been before.

In fact it replaced the vague year by the sacred year long known to the priests.

But if everything had gone on then as the priests of Tanis imagined, the Egyptian new year's day, *if* determined by the heliacal rising of Sirius, would not always afterwards have been the 1st of Payni, although the solstice and Nile flood would have been due at Memphis about the 1st of Pachons; and this is, perhaps, one among the reasons why the decree was to a large extent ignored.

Hence, for some years after the date of the decree of Tanis there were at least three years in force: the new fixed year, the new vague year, reckoning from Pachons, and the old vague year, reckoning from Thoth.

But after some years another attempt was made to get rid of all this confusion. The time was 23 B.C., 216 years after the decree of Tanis, and the place was Alexandria. Hence the new fixed year introduced is termed the Alexandrine year.

This new attempt obviously implied that the first one had failed; and the fact that the vague year was continued in the interval is sufficiently demonstrated by the fact that the new year was $\frac{216}{4} = 54$ days *en retard*. In the year of Tanis it is stated that the 1st Pachons, the new New Year's Day, the real beginning of the flood, fell on the 19th of June (Gregorian), the summer solstice, and hence the 1st of Thoth fell on the 22nd of October (Gregorian). In the Alexandrine year the 22nd of October is represented by the 29th of August, and the 19th of June by the 20th of April.

It is noteworthy that in the Alexandrine year the heliacal rising of Sirius on the 23rd of July (Julian) falls on the 29th of Epiphi, nearly the same date as that to which I first drew attention in the inscriptions of the date of Thotmes and Pepi. This, however, it is now clearly seen, is a pure accident, due to the break of continuity before the Tanis year, and the *slip* between that and the Alexandrine one. It is important to mention this, because it has been thought that somehow the "Alexandrine year" was in use in Pepi's time!

It would seem that the Alexandrine revision was final, and that the year was truly fixed, and from that time to this it has remained so, and must in the future for ever remain so. It must never be forgotten that we owe this perfection to the Egyptians.

One of the chief uses of the Egyptian calendar that has come down to us was the arrangement and dating of the chief feasts throughout the year in the different temples.

The fact that the two great complete feast calendars of Edfu and Esne refer to the only fixed years evidenced by records, those of Tanis and Alexandria, one of which was established over 200 years after the other, is of inestimable value for the investigation of the calendar and chronology of ancient Egypt.

In an excellent work of Brugsch, "Three Festival Calendars from the Temple of Apollinopolis Magna (Edfu) in Upper Egypt," we have two calendars which we can refer to fixed years, and can date with the greatest accuracy. In the case of one of these, that of Esne, this is universally recognized; as to the other, that of Apollinopolis Magna, we are indebted to the researches of Krall, who points out, however, that "it is only when the province of Egyptian mythology has been dealt with in all directions, that we can undertake a successful explanation of the festival catalogues. Even externally they show the greatest eccentricities, which are not diminished but increased on a closer investigation."

---

[1] Goodwin has already asked, "Does the Smith Papyrus refer to some rectification of the Calendar made in the 4th Dynasty, similar to that made in Europe from the old to the new style," quoted by Riel, "Sonnen- und Sirius-Jahr," p. 361.

About some points, however, there is no question. The summer solstice is attached in the Edfu calendar to the 6th Pachons, according to Krall, while the beginning of the flood is noted on the 1st of that month. In the Esne calendar, the 26th Payni is New Year's Day. We read:—"26th Payni, New Year's Day, Feast of the Revelation of Kahi in the Temple. To dress the crocodiles, as in the month of Mechir, day 8."

Peculiar to the Esne calendar, according to Krall, is the mentioning of the "New Year's Festival of the Ancestors" on the 9th of Thoth; to the Edfu calendar, publication No. 1 of Brugsch, the festival "of the offering of the first of the harvested fruits, after the precept of King Amenemhā I.," on the 1st Epiphi, and "the celebration of the feast of the great conflagration" on the 9th of Mechir. In feast calendar No. 1, the reference to the peculiar Feast of Set, is also remarkable, this was celebrated twice, first in the first days of Thoth (? 9th ?), then, as it appears, in Pachons (10th). This feast is well known to have been first mentioned under the old Pharaoh Pepi Merinrā.

It is a question whether in the new year of the ancestors and the feasts of Set, all occurring about the 9th Thoth and Pachons, we have not Memphis Festivals which gave way to Theban ones, for so far as I can make out the flood takes about nine days to pass from Thebes to Memphis, so that in Theban time the arrival of the flood at Memphis would occur on 9th or 10th Thoth. There is no difficulty about the second dating in Pachons, for as we have seen this followed on the reconstruction of the calendar.

It is also worthy of note that the feast of the "Great Conflagration" took place very near the Spring Equinox.

It is well to dwell for a moment on the Edfu inscriptions to see if we can learn from them whether they bear out or not the views brought forward with regard to this reconstruction.

As we have seen it is now acknowledged that the temple inscriptions at Edfu (which are stated to have been cut between 117 and 81 B.C.) are based upon the fixed year of Tanis; hence we should expect that the rising of Sirius would be referred to on 1 Payni, and this is so. But here, as in the other temples, we get double dates referring to the old calendars, and we find the "wounding of Set" referred to on the 1st Epiphi and the rising of Sirius referred to under 1 Mesori. Now this means, if the old vague year is referred to, as it most probably is, that

5 Epacts
30 Mesori
—
35 × 4 = 140 years

had elapsed since the beginning of a Sothic cycle, when the calendar coincidences were determined, which were afterwards inscribed on the temple walls. We have, then, 140 years to subtract from the beginning of the cycle in 270 B.C. This gives us 130 B.C., and it will be seen that this agrees as closely as can be expected with my view, whereas the inscription has no meaning at all if we take the date given by Censorinus.

I quote from Krall[2] another inscription common to Edfu and Esne, which seems to have astronomical significance.

"1. Phamenot. Festival of the suspension of the sky by Ptah, by the side of the god Harschaf, the master of Heracleopolis Magna (A1). Festival of Ptah. Feast of the suspension of the sky (Es).

"Under the 1st Phamenot, Plutarch, de Iside ac Osiride c. 43, b, notices the *ἔμβασις Ὀσίριδος εἰς τὴν σελήνην*. These are festivals connected with the celebration of the winter solstice, and the filling of the Uza-eye on the 30th Mechir. Perhaps the old year, which the Egyptians introduced into the Nile valley at the time of their immigration, and which had only 360 days, commenced with the winter solstice. Thus we should have in the 'festival of the suspension of the sky,' by the ancient god Ptah—venerated as creator of the world—a remnant of the time when the winter solstice . . . . marked the beginning of the year, and also the creation."

The reconstruction of the calendar naturally enhanced the importance of the month Pachons; this comes out very clearly from the inscriptions translated by Brugsch. On this point Krall remarks:—

"It is therefore quite right that the month Pachons, *which took the place of the old Thoth by the decree of Tanis*, should play a prominent part in the feast calendars of the days of the Ptolemies, and the first period of the Empire in general, but especially in the *Edfu* calendar, which refers to the *Tanitic* year. The first five days of Pachons are dedicated in our calendar to the celebration of the subjection of the enemies by Horus; we at once remember the above mentioned (p. 7) record of Edfu of the nature of a mythological calendar, describing the advent of the Nile flood. On the 6th of Pachons—remember the great importance of the sixes in the Ptolemæan records—the solstice is then celebrated. The Uza-eye is then filled, a mythical act which we have in another place referred to the celebration of the solstice, and "everything is performed which is ordained" in the book "on the Divine Birth."

Next let us turn to Esne. The inscriptions here are stated to be based on the Alexandrian year, but we not only find 1st Thoth given as New Year's Day, but 26 Payni given as the beginning of the Nile flood.

Now I have already stated that the Alexandrine year was practically a fixing of the vague Tanis year; that is, a year beginning on 1st Pachons in 239 B.C.

If we assume the date of the calendar coincidences recorded at Esne to have been 15 B.C. (we know it was after 23 B.C. and at the end of the Roman dominion), we have as before, seeing that, if the vague Tanis year had really continued, it would have swept forward with regard to the Nile flood,

Pachons 30
Payni 26
—
56 × 4 = 224 years after 239 B.C.

This double dating, then, proves the continuation of the vague year of Tanis if the date 15 B.C. of the inscription is about right.

Can we go further and find a trace of the old cycle beginning 270 B.C.? In this case we should have the rising of Sirius

270
− 15
——
4)255 years
——
64 = say 5 Epacts and 2 months.

This would give us 1 Epiphi. Is this mentioned in the Esne calendar? Yes, it is, "1 Epiphi. To perform the precepts of the book on the second divine birth of the child Kahi."

Now the 26th Payni, the new New's Year Day, is associated with the "revelation of Kahi," so it is not impossible that "the second divine birth" may have some dim reference to the feast.

It is not necessary to pursue this intricate subject further in this place; so intricate is it that, although the suggestions I have ventured to make on astronomical grounds seem consistent with the available facts, they are suggestions only, and a long labour on the part of Egyptologists will be needed before we can be said to be on firm ground.

J. Norman Lockyer.

[2] *Op. cit.*, p. 37.

PROPOSED HANDBOOK TO THE BRITISH MARINE FAUNA.

THE admirable monographs issued under the auspices of the Ray Society, and in Van Voorst's series, by such well-known authorities as Forbes and Hanley, Alder and Hancock, M'Intosh, Allman, Hincks, Brady, Norman, and others, are amongst the most creditable and useful productions of British Zoology, and all naturalists must devoutly trust that there are still others of a like classical nature to follow, and that, for example, Prof. M'Intosh will soon be able to complete his long-expected work on the British Polychæta.

But many Marine zoologists feel that, quite apart from such exhaustive and expensive monographs, and only aspiring to occupy a very much humbler position, there is pressing need of a "pocket" or seaside "Invertebrate Fauna," which could be used in much the same way as the botanists' "Field Flora." It has been suggested to me more than once during the last few years that I would be doing useful work in compiling such a book; and as no one else seems ready or willing to do so, I feel inclined to make the attempt. Some material has already been accumulated for the purpose, but before going further I wish to lay my views before my fellow zoologists, in the hope that they will be kind enough to criticize the scheme and give me the benefit of their advice.

The only existing work of the kind is Gosse's well-known, and, so far as it goes, very excellent little "Manual of Marine Zoology," but that book does not really meet the present want, as not only is the date of publication 1855-6, since when the number of genera and species has probably been something like doubled, but also Gosse merely gives the names of the species, while the book I think of would, in order to be of any real use, require to aim at giving a brief but sufficient diagnosis and figure of every British species. I would adopt as "British" the area defined by Canon Norman's British Association Committee in 1887.

Probably the most convenient form of publication would be some four to six small volumes, each dealing with one or two of the large groups. This would allow of the groups being published as they were ready, not necessarily in zoological order, and would also be convenient for the use of those interested in one set of animals.

There would be definitions—perhaps with occasional analytical tables or keys—of orders, families, &c., down to and including genera. Under each genus would be given all sufficiently defined species with a brief description of each either in tabular form or in series, as seems most suitable in each case, and with an indication of size, range, and habitat. Many species might be described very briefly in terms of preceding species, the differences merely being pointed out. By simplicity of language, avoidance of unnecessary repetition, and use of contractions it might be hoped that each species could be confined on an average to a couple of lines.

Illustrations would be either in the form of numerous small outline figures on thin paper plates inserted as near as possible to the pages where the descriptions occur, or as small groups of cuts (as in "Gosse") in the text. There would be a figure of the whole animal in each important genus, or small family, and the figures of the species would represent the diagnostic points only, *e.g.* in the zoophytes there would be a figure in the genus *Plumularia* of an entire colony, or shoot, while the species *pinnata*, *setacea*, *catharina*, &c., would be represented each by a small figure showing the pinnæ, calycles, or nematophores as the case required.

I shall now give a few examples, taken from different groups, of the method in which the genera and species might be treated, in order that specialists may have the opportunity of judging and criticizing.

I. From Cœlenterata:—Genus ANTENNULARIA.
Stems simple or branched; pinnæ verticillate; nematophores along the stems; gonothecæ axillary, unilateral.
A. antennina, L., stems clustered, usually simple; hydrothecæ separated by 2 joints. 6 to 9 in. high. Gen. distr. deep w.
A. ramosa, Lamk., stems single, usually branched; hydrothecæ separated by 1 joint only. 6 to 9 in. high. Gen. distr. deep w.

II. From Crustacea:—Family MAIIDÆ.
HYAS. Carapace tuberculous, no spines; branches of rostrum not divaricated; second joint of antenna dilated; no teeth beneath last joint of walking legs.
H. araneus, L., carapace not contracted behind post-orbital process. 3 in. Common, shallow.
H. coarctatus, Leach, carapace contracted behind post-orbital process. 1 in. Gen. distr. shallow.
PISA. Carapace may be tuberculous, with strong postero-lateral spine; branches of rostrum divaricated at extremity; second joint of antenna slender; terminal joint of walking legs toothed beneath.
P. tetraodon, Leach, carapace with small tubercles; antero-lateral margin with 4 spines. 2 in. Rare, S. coast.
P. gibbsii, Leach, carapace with large rounded elevations, but no tubercles, no spines on antero-lateral margin. Rare, deep w., S. coast.
MAIA. Carapace covered with numerous sharp spines; branches of rostrum strongly divaricated; no teeth beneath terminal joint of walking legs.
M. squinado, Latr. 10 in. long. S. and W. coasts o England.

III. From Tunicata:—Family MOLGULIDÆ.
EUGYRA. Branchial sac with no folds.
E. glutinans. Möll., circular area on side free from sand. ½ in. Shallow w., gen. distr.
E. globosa, Hanc., entirely covered with sand. ½ in.
PERA. Bran. s. with 5 folds each side.
P. hancocki, Hrdn., matted fibres at poster. end. ½ in. Irish Sea, 20 fms.
MOLGULA. Bran. s. with 6 or 7 folds each side.
M. inconspicua, A. & H., 6 folds, sandy, dors. lam. entire, no pap. on stigmata. ¼ in.
M. impura, Hel., 6 folds, sandy, small papillæ on edges of stigmata. 1 in. W. of Ireland, shallow.
M. simplex, A. & H., few hairs, little or no sand, 6 folds, anus fringed, dors. tub. horse-shoe, aperture to left. ½–¾ in.
M. tubifera, Örst., 6 folds, anus fringed, dors. tub. horse-shoe, dors. lam. toothed, sandy. 1 in. E. coast.
M. ampulloides, v. Ben., 6 folds, anus fringed, dors. tub. horse-shoe, 3 bars on fold, dors. lam. entire. 1 in. E. coast, shallow.
M. socialis, Ald., 6 folds, anus fringed, dors. tub. horse-shoe, 4 bars on fold, dors. lam. entire, sandy, gregarious. ½ in. shallow w. S. coast.
M. holtiana, Hrdn., 6 folds, dors. tub. serpentif., hairs but little sand on test. ¾ in. W. of Ireland, 10 fms.
M. occulta, Kupf., 7 folds, dors. tub. horse-shoe, dors. lam. toothed, whole body sandy. 1 in. Shallow w. S. and W. coasts.
M. oculata, Forb., 7 folds, siphonal region alone free from sand, and retractile between folds of test. 1 in. Gen. distr. Shallow w.
M. cæpiformis, Hrdn., 7 folds, globular, not attached, no sand. ¾ in. S. coast, shallow w.
M. citrina, A. & H., 7 folds, attached by left side, no sand. ¼–½ in. under st., litt. E. and W. coasts.
CTENICELLA, as MOLGULA, but branchial and atrial lobes laciniated.
C. complanata, A. & H., 6 folds on left, 7 on right, depressed, attached, sandy, ¼ in.

In conclusion, I need scarcely say that I shall be very grateful for suggestions, and, if the work is carried on, for any information from specialists about less known species, and the discrimination of allied forms, and for specimens, and also for references to any descriptions which might be likely to escape my notice.

W. A. HERDMAN.

NOTES.

IN consequence of the unavoidable absence abroad of the new President of the Institution of Electrical Engineers, Mr. W. H. Preece, F.R.S., on the 12th inst., he will deliver his inaugural address on the 26th inst.

A PUBLIC meeting, arranged by the Technical Instruction Committee of the Essex County Council, will be held in the Shire Hall, Chelmsford, on Friday afternoon, January 13, at 4.30 p.m., Lord Rayleigh in the chair. An address will be given by Sir Henry E. Roscoe on technical instruction in agricultural counties, with especial reference to science teaching. Afterwards a discussion will take place.

DR. PERCY RENDALL, F.Z.S., has accepted an appointment as Resident Medical Officer to the Sheba Gold-mining Company in the Barberton District of the Transvaal. He will reside at Eureka City, at an elevation of 5000 feet above the sea-level. Dr. Rendall made a good collection of birds during his recent residence at Bathurst on the Gambia, of which he has given an account in the *Ibis* for last year (*Ibis*, 1892, p. 215). He has also made many valuable donations to the Zoological Society's Menagerie, amongst which is the unique example of the Nagor Antelope (*Cervicapra redunca*), presented by him in June, 1890. Of this scarce animal there is, we believe, no example in the British Museum. Dr. Rendall's new appointment will give him many opportunities of extending our zoological knowledge of a little known district.

LORD WALSINGHAM, who has devoted much of his attention to the micro-lepidoptera, has filled the vacancy on the staff of the *Entomologists' Monthly Magazine* occasioned by the death of Mr. Stainton.

LAST week a preliminary meeting was held at the house of Sir James Paget to consider what steps should be taken with regard to a memorial of Sir Richard Owen. It was decided that a committee should be formed to make the necessary preparations. The following, among others, have consented to serve as members :—The Presidents of the Royal Colleges of Physicians and Surgeons and of most of the scientific societies, the Duke of Teck, Lord Playfair, Prof. Huxley, Sir Joseph Hooker, Sir Henry Acland, Sir John Evans, Dr. Michael Foster, Mr. Sclater, Sir W. Savory, Mr. Hulke, Sir Joseph Fayrer, Sir Edward Fry, Dr. Günther, Mr. Carruthers and Dr. H. Woodward. Sir William Flower will act as treasurer, and a general meeting will shortly be called. It has been suggested that the memorial should be a marble statue, to be placed in the hall of the Natural History Museum.

PROF. WESTWOOD, who died on Monday at the age of eighty-seven, will be greatly missed at Oxford. To most people he is known chiefly as a writer on the archæology and palæography of art, but he was equally eminent as an entomologist. He was one of the founders of the Entomological Society, and received one of the Royal Society's gold medals for his entomological researches.

WE regret to record the death of General Axel Wilhelmovitch Gadolin, an old member of the Russian Academy of Sciences. He was born of Finnish parents on July 10, 1828, received his education in the Finnish Corps of Cadets, and till his death remained in the Russian Artillery, devoting his leisure time to mineralogical, and especially to mathematical, researches into the molecular forces which act in the formation of crystals. One of his earlier works, published in the *Verhandlungen der Mineralogischen Gesellschaft zu St. Petersburg*, was on some minerals from Pitkäranta. His chief work, published in 1867, was his "Deduction of all the Systems of Crystals and their Derivates from a Unique Principle." A deep impression was produced upon the members of the Russian Mineralogical Society by Gadolin's first communication upon this subject. The lucidity with which he deduced all systems of crystallization from fundamental principles of equilibrium of molecular forces, and the simplicity of the exposition of his researches, entirely based upon high mathematical analysis, reminded his hearers of some of the best pages of Laplace's writings. The work soon became widely known in a German translation. A paper on the resistance of the walls of a gun to the pressure of gunpowder gases also deserves mention, as, in addition to the formerly known formulæ of highest resistance of cylinders, he gave a new formula of minimal resistance. Later on his method was used with great success by Klebsch, in his well-known "Theorie der Elasticität fester Körper," for deducing some general equations of equilibrium of solid bodies.

THE last issue of the *Izvestia* of the East Siberian Geographical Society (vol. xxiii. 3) contains an obituary notice by V. Obrutcheff, of I. D. Chersky, who died in the far north-east of Siberia, during his expedition to the Kolyma river, after having given many years of his life to the active geological exploration of Siberia. He began his work in 1872 at Omsk, where he made most valuable discoveries of post-tertiary mammals. During the next two years he explored the Tunka and Kitoi Alps, but his rich materials were lost during the great conflagration at Irkutsk in 1879. In 1875 and 1876 he explored the Nijneudinsk caves, making again remarkable finds of quaternary mammals ; and then he gave fully five years to the study of the stores of Lake Baikal, embodying the results of his extensive researches in a map (6·7 miles to the inch), and in vol. xii. of the *Memoirs* of the East Siberian Society, and vol. xv. of the *Memoirs* of the Russian Geographical Society. In 1882 and 1883 he explored the Lower Tunguska, and again made rich finds of fossil mammals. The next five years he spent at the Academy of St. Petersburg, preparing the part of Ritter's "Asia" which is devoted to Lake Baikal, and working out the rich materials collected by another lamented Polish explorer of East Siberia, Czekanowski. He also worked out the collections brought in from the New Siberia Islands by MM. Bunge and Toll, and came to such interesting and new conclusions as to the recent geological history of Arctic Siberia, that the Academy of Sciences sent him out in 1891, at the head of a new expedition to the Kolyma region. There he died, in the midst of his promising work.

THE twentieth annual dinner of the old students of the Royal School of Mines will be held at the Holborn Restaurant, on Tuesday, January 10, at 7 o'clock. The chair will be taken by Mr. W. Gowland, late of the Imperial Mint, Osaka, Japan.

MR. G. T. ATKINSON has been appointed Professor of Cryptogamic Botany at Cornell University, Ithaca, State of New York, in the place of Prof. W. R. Dudley, who has gone to the Leland-Stanford University, Paolo Alto, California.

AT the next public meeting of the French Academy, in December 1893, forty-five prizes will be awarded for the best work tending to the advancement of the various branches of science. Of these, the following are, by the terms of the bequests, open to competitors of all nationalities. The Prix Lalande will be awarded for the most intereresting observation, or the memoir or work most useful for the progress of Astronomy. Its value is 540 francs. The Prix Valz, of 460 francs, is offered under the same conditions. Three prizes of 10,000 francs each, bequeathed by M. L. La Caze, will be awarded annually for the best contributions to Physiology, Physics, and Chemistry respectively. The Prix Tchihatchef, of 3000 francs, is offered annually to naturalists who have distinguished themselves most in the exploration of the continent of Asia or the adjacent isles excluding better known regions such as British India, Siberia proper, Asia Minor, and Syria. The explorations must have some object connected with Natural Science, physical or mathematical, and will not be awarded for archæological or ethnographic work. All these prizes will be awarded in December 1893. Works for competition to be sent in to the *Sécrétariat* before June 1. The Prix Leconte, of 50,000 francs, for the most important scientific discovery, will be awarded in 1895.

THE Royal Academy of Sciences of Turin, in accordance with the will of Dr. Cesare Alessandro Bressa, and in conformity with the programme published December 7, 1876, announces that the term for competition for scientific works and discoveries in the years 1889–92, to which only Italian authors and inventors were entitled, was closed on December 31, 1892. The ninth Bressa prize will be given to the scientific author or inventor, whatever be his nationality, who during the years 1891–94, "according to the judgment of the Royal Academy of Sciences of Turin, shall have made the most important and useful discovery, or published the most valuable work on physical and experimental science, natural history, mathematics, chemistry, physiology and pathology, as well as geology, history, geography and statistics." The term will be closed at the end of December 1894. The sum fixed for the prize, income tax being deducted, is 10,416 francs. Any one who proposes to compete must declare his intention within the time above mentioned, by means of a letter addressed to the President of the Academy, and send the work he wishes to be considered. The work must be printed. Works which do not obtain the prize will be returned to the authors, when asked for within six months from the adjudication of the prize. None of the national members, resident or not resident, of the Turin Academy can obtain the prize. The Academy gives the prize to the scientific man considered most worthy of it, even if he has not competed.

MESSRS. MACMILLAN AND CO. hope to publish early in the spring the second volume of Dr. Arthur Gamgee's Treatise on Physiological Chemistry. This volume, which deals with the Digestive Processes, will be followed at no long interval by an enlarged and revised edition of the first volume, which originally appeared in 1880.

THE United States Government is inviting the various European Governments to send delegates to an International Conference of Meteorologists, to be held at Washington. The following is said to be proposed as a provisional programme of topics to be discussed by the Conference: (*a*) The organization of additional meteorological work for the benefit of agriculture. (*b*) The extension to all ports frequented by commerce of the benefits of systematic storm and weather signals, and the introduction of a uniform system of storm warnings throughout the world. (*c*) The co-operation of all nations in the publication of a daily chart of the weather over all the habited lands and frequented oceans for the study of the atmosphere as a whole, and as preparatory to the eventual possibility of predicting important changes several days in advance. (*d*) The equable apportionment of stations, publications, and expenses among the nations, and the suggestion of practical methods by which to secure observations from those countries that are not represented in this Conference. (*e*) The encouragement by the respective Governments of special scientific investigations looking to the advancement of meteorology. Such other matters as the delegates may think advisable to submit for discussion, or for future report, will also be considered.

DURING the past week the sharp frost has continued almost uninterruptedly over these islands, with the exception of a partial thaw on Friday and Saturday, caused by a disturbance in the west spreading to the eastward. The greatest increase of temperature occurred in the north and west, but in the south-east of England the day readings were only slightly above the freezing-point. There was a complete change in the type of weather at the close of the week; a large anticyclone had formed over Scandinavia, and the air over nearly the whole of Europe was intensely cold, the minimum in the shade at Haparanda on Sunday registering 72° below the freezing-point, and the barometer on subsequent days rose to 31 inches and upwards in these islands. These conditions were accompanied by cold easterly gales in the south-west of England, while a heavy fall of snow was experienced in the south-eastern districts. On the coast of Kent the shade minimum fell to 11° during Monday night. The *Weekly Weather Report* issued on December 31 shows that the temperature of that period was much below the mean, amounting to 9° or 10° over the greater part of England, and to 12° in the Midland counties. Very little rain fell during the week; the deficiency of rainfall in the south-western district of England for the last year amounts to 10·8 inches, or more than 25 per cent. below the average of the 25 years 1866–90. A good deal of fog was experienced at the inland stations during the week.

SOME very interesting entomological notes from the Eastern Archipelago are given by Mr. J. J. Walker in the January number of the *Entomologists' Monthly Magazine*. Incidentally Mr. Walker mentions that Dr. Wallace's residence in these islands, after a lapse of more than thirty years, is not forgotten, and that the Dutch translation of the "Malay Archipelago" is "as highly appreciated in the lands of which he gives so vivid a picture as the original work is at home."

AT the Physikalisch-Technische Reichsanstalt, Berlin, copies of standard mercury resistances are being constructed in which the mercury does not require renewal (*Wiedemann's Annalen*). They consist of U-shaped tubes filled with mercury in a vacuum and then sealed by fusion. Into each of the ends are fused three thin platinum wires connecting with the main current, the secondary circuit, and the galvanometer respectively. Since the connections are rigidly joined to the glass, it is possible to employ platinum wires as thin as 0·3 mm. so that there is no danger of heat being conducted into the mercury from without. The copy, mounted in a perforated brass box with an ebonite lid, is immersed in petroleum contained in another brass box, so that the binding screws are covered. This box is again surrounded during the experiment with a mixture of fine ice and water. The resistance is thus taken at a temperature which can easily be obtained, and which is uniform throughout the containing vessel.

AN apparatus for demonstrating the difference of potential at the poles of a galvanic cell has been constructed by Messrs. Elster and Geitel, of Wolfenbüttel (*Zeitschr. für Phys. und Chem. Unterricht*). It is a modification of Thomson's water-dropping influence machine. Two insulated metallic vessels can be filled with water by pressing a rubber ball communicating with a three-necked jar. The jets enter the vessels through two metal rings. One of these rings is connected with the positive pole of the cell. The jet on passing through becomes negatively charged, and the charge is communicated to the vessel and through a wire to the second ring, which acts by induction on the other jet. A strong positive charge is soon accumulated on the outside of the second vessel, and can be exhibited by a gold leaf or aluminium foil electroscope.

IN 1869 it was decided, in France, to give a medal and pension of 250 francs to every old soldier of the Republic and the Empire who could show two years of service, or two campaigns, or a wound. An interesting statistical record of these "médaillés de Sainte Hélène" as of "a generation which is disappearing," is given by M. Turquan in the *Revue Scientifique*. The first list, in 1870, comprised 43,592 names; and these men must have almost exclusively served under the Empire. They are now reduced to 27. The oldest, Vivien by name, a Lyons man, is now 106. When 13 he was with Bonaparte in Egypt, fought in 22 campaigns, and was one of the Imperial Guard at Waterloo. The youngest is 92, and served in the navy. The mean age of the 27 survivors is 97 or 98 years. The annual number of deaths in this body of men reached a maximum of 6456 in 1872, since which year it has been gradually diminishing. The proportional mortality rose, in general, till 1889, but in the years since there has been a marked fall, testifying to the exceptional vitality of those late survivors. M. Turquan calculates that this remnant will have wholly disappeared by the end of the century. Going back to 1815, he estimates the generation to which the men belong at about 300,000, with a mean age of 25 years, and that 500,000 births between 1785 and 1795 would concur to its formation. From figures relating to the Napoleonic wars he comes to the grim conclusion that one man in five of those born between the years just named was destined to die in war. It is, he says, to the immense losses of men during the ten years of war of the Empire that the present generations owe their low birth-rate.

MR. J. R. S. CLIFFORD offers some interesting observations in the January number of *Nature Notes*—the Selborne Society's magazine—on the Death's-head moth and bees. Last July a friend of his at Gravesend found one of these huge moths trying to gain access to a hive, having evidently been drawn to the spot by the odour of the honey. This disposes of doubts which have been suggested as to the old statements about this moth's habit of entering hives when it has a chance. The construction of modern hives keeps it out, but "where old-style hives are used, the moth can and does enter, and occasionally one has been found dead within a hive, the bees, being unable to remove so bulky an insect, having taken the precaution to embalm its body with what is called *propolis*." According to Mr. Clifford, some Continental bee-keepers have discovered that "the bees are aware they are liable to the intrusions of this big moth," and when the bees are "located in the old-fashioned hive, the insects erect a kind of fortification at the portal. This is constructed with a narrow passage and a bend, past which the Death's-head could not possibly make its way, and which it has no jaws to bite through."

WE learn from the *Agricultural Journal*, issued by the Department of Agriculture at Cape Colony, that much attention is being given there to questions connected with the fruit export trade. The department is in correspondence with the steamship companies with a view to securing every possible encouragement to the trade, which is expected to be taken up on a considerable scale this year. Replying to inquiries on the subject, the Castle Mail Packets Company announce that they will give every publicity to the rates of freight to be charged and the stowage arrangements, &c. The Company will also concede a somewhat lower rate for the less remunerative fruits carried in the cool chambers, and will reserve a cool and well-ventilated part of the vessel for conveyance of fruit as ordinary cargo. Careful instructions have been issued to captains of the Company's vessels in regard to the stowage and carriage of fruit.

DR. THEODORE MAXWELL has issued a useful catalogue of Russian medical dissertations and other works he has collected and presented to the Royal College of Surgeons of England. In order that the dissertations may be of service to students who do not read Russian, he has indicated the nature of each work in English, and has given references to such abstracts in the *Lancet* or elsewhere as he has himself made or happens to be acquainted with.

AN excellent "Child Life Almanack" for 1893, by A. M. Clive Bayley, has been published by Messrs. G. Philip and Son. It is issued as an extra number of "Child Life," and the object, as the author explains, is to provide teachers with suggestions both for lessons to be prepared and observations to be made. Teachers who may wish to give "seasonable" lessons will find many most useful hints as to what really goes on in nature during the various periods of the year.

MR. JOHN BROWNING, optical and physical instrument maker, has issued an illustrated catalogue of magic, dissolving view, and optical lanterns, lime-light apparatus, and slides.

THE extraordinary diversity in the temperature at which different micro-organisms flourish and multiply, has from time to time been the subject of some interesting investigations by Fischer, Globig, and others. Thus Fischer isolated fourteen different species of bacteria from the sea-water in Kiel harbour, and from soil in the town itself. These he was actually able to cultivate successfully at the freezing temperature (0° C.) as well as at from 15° to 20° C. Globig, on the other hand, studied the behaviour of micro-organisms at high temperatures and separated out no less than thirty varieties from garden soil which would grow at 60° C. Some of these were even able to develop at 70° C., whilst the majority refused to grow at all below 50° C., some still more fastidious individuals objected to any temperature below 60° C., and others again required a temperature of between 54° and 68° C. One bacillus, however, was discovered more catholic in its taste in this respect, for whilst growing at 68° C. it managed to develop also at from 15° to 20° C. Some fresh contributions on the growth of micro-organisms at low temperatures have recently been made by Forster of Amsterdam ("*Ueber die Entwickelung von Bakterien bei niederen Temperaturen*"). As far back as 1887 Forster described a phosphorescent bacillus obtained from sea-water which was found not only capable of growing, but of producing the phenomenon of phosphorescence at 0° C. In further researches made by this investigator in conjunction with Bleekrode, it is stated that, although not many different species were found by them to develop at 0° C., yet immense numbers of individual bacteria belonging to this category were detected in very various media. Thus one cubic centimetre of milk as sent into the market contained 1000 such micro-organisms, whilst in a single gram of garden soil as many as 140,000 were found. Large numbers of such bacteria were also present in sea-water obtained from the North Sea, and they were also found on the surface of fresh water fish as well as in their alimentary tract. It is well known that to successfully preserve meat and other articles of food it is necessary to employ a much lower temperature than 0° C., and experience has further shown that this is best done when the atmosphere is deprived of all moisture, as is accomplished by the compression and subsequent expansion of the air in enclosed spaces. Haddocks imported from Norway and thus artificially frozen were examined by Forster for bacteria. These fish were first killed and then exposed to a temperature of from 20° to 40° below 0° C. until they became perfectly hard and stiffly frozen, when they were removed to a cold chamber in which the temperature varied from 8° to 15° below 0° C. In spite of the extremely low temperature to which these fish had been subjected, on examining them when still hard frozen, a considerable number of bacteria were found in the abdominal cavity which had been opened when the fish was killed. It is obvious that during the interval which elapsed between the killing of the fish and their transference to the freezing chamber, bacteria must have been able to gain access, but had not had time to multiply to any considerable extent before the fish was frozen. Forster points out, what is sufficiently apparent, that the packing of samples of water in ice when sent from a distance for bacteriological examination to prevent the multiplication of the micro-organisms present, is really of very little if any use at all. Thus it was already shown several years ago by Percy Frankland that the bacteria in filtered Thames water were able to multiply extensively, even when preserved for some days in a refrigerator.

The additions to the Zoological Society's Gardens during the past week include a Bittern (*Botaurus stellaris*), European, presented by Lord Ilchester, F.Z.S.; two Hamsters (*Cricetus frumentarius*), British, presented by Miss Pugh; two Alligators (*Alligators mississippiensis*), from Florida, presented by Master Williams; a Common Snipe (*Gallinago cœlestis*), British, purchased.

OUR ASTRONOMICAL COLUMN.

Comet Holmes (November 6, 1892).—The following is a continuation of Herr Berberich's ephemeris of this comet, the places being for Berlin, midnight:—

	R.A. h. m. s.	Decl. ° ′	Log *r*.	Log Δ.
Jan. 5 ...	1 8 50 ...	+33 47·9 ...	0·4119 ...	0·3400
6 ...	9 59 ...	46·4		
7 ...	11 8 ...	45·0		
8 ...	12 18 ...	43·7		
9 ...	13 30 ...	42·6 ...	0·4143 ...	0·3516

The comet is now near to and south following β Andromedæ. Reports from various Observatories state that the comet is now very dim.

Comet Brooks (November 20, 1892).—This comet is now travelling very quickly. The ephemeris for Berlin, midnight, is continued below:—

	R.A. h. m. s.	Decl. ° ′	Log *r*.	Log Δ.	Br.
Jan.] 5 ...	18 29 40	+66 5·4 ...	0·0805 ...	9·8562 ...	7·82
6 ...	19 0 49 ...	13·6			
7 ...	19 31 22 ...	65 59·2			
8 ...	20 0 22 ...	24·6 ...	0·0806 ...	9·8651 ...	7·49
9 ...	20 27 8 ...	64 32·4			
10 ...	20 51 19	+63 26·0 ...	0·0811 ...	9·8781 ..	7·01

The unit of brightness is taken as that at midnight on November 21.

The track of the comet lies near the pole of the ecliptic, in the constellation Draco.

The Spectrum of Comet Holmes.—The spectrum of the comet appears to have been continuous without any trace of bright bands. At South Kensington it appeared to have its brightest part near the chief carbon fluting (λ 517), but there was nothing which could be described as a line or fluting. As might be expected, there was a brighter continuous spectrum from the nucleus. The same result was obtained by Mr. Campbell at the Lick Observatory, and by Prof. Keeler at the Allegheny Observatory. The latter observer remarks that the spectrum is just what we should expect if the comet shines entirely by reflected sunlight.

The Recent Opposition of Mars.—In the December number of *Astronomy and Astro-Physics*, Prof. W. H. Pickering summarizes the conclusions derived from the observations of Mars at Arequipa as follows: (1) That the polar caps are clearly distinct in appearance from the cloud formations, and are not to be confounded with them. (2) That clouds undoubtedly exist upon the planet, differing, however, in some respects from those upon the earth, chiefly as regards their density and whiteness. (3) There are two permanently dark regions upon the planet, which under favourable circumstances appear blue, and are presumably due to water. (4) Certain other portions of the surface of the planet are undoubtedly subject to gradual changes of colour, not to be explained by clouds. (5) Excepting the two very dark regions referred to above, all of the shaded regions upon the planet have at times a greenish tint. At other times they appear absolutely colourless. Clearly marked green regions are sometimes seen near the poles. (6) Numerous so-called canals exist upon the planet, substantially as drawn by Prof. Schiaparelli. Some of them are only a few miles in breadth. No striking instances of duplication have been seen at this opposition. (7) Through the shaded regions run certain curved branching dark lines. They are too wide for rivers, but may indicate their courses. (8) Scattered over the surface of the planet, chiefly on the side opposite to the two seas, we have found a large number of minute black points. They occur almost without exception at the junctions of the canals with one another and with the shaded portions of the planet. They range from thirty to one hundred miles in diameter, and in some cases are smaller than the canals in which they are situated. Over forty of them have been discovered, and for convenience we have termed them lakes.

The heights of some of the clouds were found to be not less than twenty miles, and indirect observations have led to the conclusion that the density of the atmosphere of the planet is less than that at the surface of the earth, but probably not as much as ten times less.

Prof. Pickering is of opinion that the opposition of 1894 will be quite as valuable to observers as that of 1892, the distance being but little greater, while the planet will be much farther north, and there is less likelihood of the surface being so much obscured by clouds as during the recent opposition.

GEOGRAPHICAL NOTES

An interesting illustration of the rapid development of South Africa is given by the recent appointment of a magistrate to reside near Lake Ngami to protect the interests of white traders, and enforce the laws restricting the sale of liquor and ammunition to the natives.

The January number of the *Geographical Journal*, the new form of the Proceedings of the Royal Geographical Society, contains a paper and map of some importance by Mr. A. P. Harper, descriptive of the central part of the Southern Alps of New Zealand. Government surveyors have been sent for several seasons to map out the glaciers, and an effort is being made by thoroughly exploring and mapping the region to make it the Switzerland of the southern hemisphere in the estimation of tourists, as it is already by virtue of its fine mountain systems.

An important paper on the physical conditions of the waters of the English Channel is published by Mr. H. N. Dickson in the new number of the *Scottish Geographical Magazine*. He shows how the ebb and flow of the tides in the Channel is affected by the characteristic form of the main feature of the coast-line, viz. bays with the western side running nearly from south to north, turning at a sharp angle, and lying open to the east. The circulation of the water and its temperature were found to be largely determined by these conditions.

Mr. Coles gave a successful lecture to young people in the hall of the University of London, on Friday last, covering the first half of his subject, "All the World Over," in a very interesting way. Anecdotes of personal adventure combined with exceptionally fine limelight views of scenery to give a vivid impression of the regions touched upon. The second and last juvenile lecture, under the authority of the Royal Geographical Society, will be given on Friday, January 6, at 4 p.m.

The Royal Scottish Geographical Society announces a course of educational lectures in continuation of those delivered by Prof. J. Geikie and Dr. H. R. Mill last year. The new course will be on the Geographical Distribution of Animals, by Mr. J. Arthur Thomson, who is at present delivering the Thomson Lectures at Aberdeen. The Society has also provided two special lectures to young people, by Prof. C. G. Knott, on Life in Japan, and by Mr. Graham Kerr on his recent travels in South America.

We understand that a book of travel in Madagascar and Africa, by Mrs. Colvile, F.R.G.S., describing the observations of the authoress on a recent extensive tour, will shortly be published by Messrs. Blackwood.

Mr. J. W. Gregory, assistant in the Geological Department of the British Museum, has joined as naturalist the sporting expedition of Lieutenant Villiers and others, which is on the point of starting up the Juba. From Bardera, the head of navigation, the party will traverse unknown regions to Lake Rudolf, and from there attempt to cross in a north-easterly direction, through the Galla country and Somaliland to Berbera, on the Gulf of Aden.

THE INTERNATIONAL ZOOLOGICAL CONGRESS AT MOSCOW.

THE International Zoological Congress held its second session in Moscow during the month of August last, and with most commendable zeal the committee, to whose care the editing and publishing of the memoirs read were committed, now publish the first part of the volume of its Proceedings. This part is printed in royal octavo size, and contains 350 pages, with several illustrations. All the memoirs are in French, thirteen out of the total thirty having been translated from, it is presumed, Russian. In the first section—that of questions concerning biology and systematic and faunistic zoology from a general standpoint—there are three papers. J. de Kennel replies to the queries of Prof. L. Cosmovici: (1) On a definite arrangement of the animal kingdom in "Phyla"; (2) is there a type "Vermes"? (3) on a uniform terminology of the secretory organs of worms. Ch. Girard on some points of nomenclature. J. de Bédriaga on introduced species, and on hybrids, reptilian and amphibian. In Section II.—the same subjects from a special standpoint—there are twelve papers:—P. N. Boutchinsky, on the Black Sea fauna; refers to a report on invertebrates of the Bay of Sebastopol by Péréïaslavtzeva, who records 639 forms found. He describes three zones: (1) from the surface to a depth of 175 feet; (2) from 175 to 280 feet in depth, with a minimum temperature of 6–7° C.; and (3) from 280 to 700 feet, with a slightly higher temperature than in the previous zone, 8–9° C. From a depth of 700 feet the water contains a quantity, more or less large, of sulphureted hydrogen, the quantity notably increasing with the depth. T. J. Van-Beneden gives a note on the living and extinct Cetacea of the same sea. Gr. Kojevnikov gives an account of the fauna of the eastern Baltic based on many recent explorations. Dr. J. de Bédriaga treats of European and circum-mediterranean vipers. C. Grévé has a paper on the geographical distribution of the Carnivores, and T. Richard, one on the geographical distribution of the Cladocerous crustacea. H. de Jhéring makes some observations on insects' nests made of clay. Prof. A. Brandt gives a classification of animal variations according to their causation. Prof. A. Milne Edwards and E. L. Bouvier give a most interesting account of the varieties and distribution of *Parapagurus pilosimanus*, S. T. Smith. A table with the comparative measurements of forty-two specimens, is appended. *P. abyssorum* and var. *scaber*, are reduced to the first named species. F. Vejdovsky describes *Thuricola gruberi*, n. sp., and *Monodontophrya longissime*, gen. et sp. nov., the former from a stream near Bodenbach, the latter in the alimentary tract and body cavity of *Rhynchelmis limosella*, Hofm. In a short note Dr. J. de Bédriaga calls attention to some differences between *Chalcides simonyi*, Steind., and *C. viridanus*, which forms Boulenger and Steindacher have proposed to unite, and thinks that *Molge luschani*, Steind., neither belongs to Molge nor to Salamander, but to a European and American genus, not however named by him.

The third section contains eight papers on histology and embryology. N. Kholodovski, contributions to a mesoderm and metamere theory. A. Ptitzine, note on the formation of the germ of the peripheric nervous system. V. Roudnev, note on the development of the cardiac endothelium in Amphibians. Mme. O. Tikhomirova, on the development of *Chrysopa perla*. Fr. Vejdovsky, on the segmentation of the ovum and the formation of the blastoderm in the Pseudoscorpiones, and on a rudimentary organ in the same. N. Koulaguine, contribution towards the history of the parasitic hymenoptera. A. Tikhomirov, value of embryological research for classification. Section IV., physiology:—C. Khvorostansky, on the luminosity of animals from the White Sea.

In Section V., devoted to morphology and comparative anatomy, L. Cosmovici writes as to the purport of the "aquiferous system," "segmentary organs," "excretory organs," and "nephridia." H. de Jhéring, on the presence or absence of an excretory apparatus in the genital organs of the metazoa. P. Mitrophanov, note on the metameric significance of the cranial nerves. N. Nassonov, on the position of the Strepsiptera in the animal system, according to the facts of post-embryonal development and of anatomy. A. O. Kovalevsky, on the excretory organs of the terrestrial Arthropods. N. Zograf, on the origin and parentage of the Arthropods, more especially the tracheal bearing forms.

A BOTANIST'S VACATION IN THE HAWAIIAN ISLANDS.

THE new number of the American *Botanical Gazette* (vol. xvii., No. 12) contains the first part of a paper by Prof. D. H. Campbell, describing his experiences during a vacation spent last summer in the Hawaiian Islands. We reprint the following passage:—

On awakening upon the seventh day out, and looking through the port-hole of my state-room, I saw that we were sailing near land. Rugged barren looking hills were seen; and, going upon deck, I learned that this was Oahu, the island upon which Honolulu is situated. As we skirted the shore at a distance, I soon spied a grove of unmistakable cocoa palms, the first hint of the tropical vegetation to which I was soon to be introduced. Beyond was the bold promontory of Diamond Head, an extinct volcanic crater, forming a great bowl with rugged sides, right at the water's edge. Beyond this, and bounded partly by it, is the bay upon whose shores stands the city. Back of it rose abruptly a chain of mountains, in places about three thousand feet above sea-level, and furrowed by deep valleys, whose walls, as well as the cloud-capped summits of the hills, were covered with the most wonderfully verdant vegetation. Never before had I realized the possibilities of green. Blue greens, yellow greens, gray greens, and positive greens, with all degrees of these and others that are indescribable, combined to form what Whistler would term a symphony in green.

As if to vie with the colours of the mountains, the sea exhibited an equally wonderful variety of tints. Outside the harbour is a coral reef, and within this the water is of the pale green common to shallow ocean water; but outside it deepens very rapidly into the vivid blue of the open ocean. From a distance the line is clearly seen; but, as the observer approaches shore, the water changes from deep blue through every shade of blue and green until the pale green of the water within the harbour is reached.

As we approached land numbers of the queer outrigger canoes of the natives were met, and from the wharf boys jumped into the water and swam about the ship in the hope of persuading some of the passengers to throw over to them coins, which they were very skilful in diving for.

On the way to the hotel a few gardens were passed, and in them everything was strange. By far the most striking thing was the superb *Poinciana regia.* Although I had never seen this before I recognized it in an instant from a description of Charles Kingsley's, read long ago. Surely in the whole vegetable kingdom there is no more splendid plant. A spreading flat-topped tree, perhaps thirty feet high, with feathery green, acacia-like foliage and immense flat clusters of big flaming scarlet flowers that almost completely hide the leaves so that the tree looks like an immense bouquet. They were in their prime about the time of my arrival in Honolulu, and continued to flower more or less for the next six weeks. Pretty much everything in Honolulu, except the cocoanuts and an occasional haw tree (*Paritium tiliaceum*) is planted; but people seem to vie with each other in seeing how many different kinds of plants they can grow, and the result is that the place is like one great botanical garden. To Dr. Hillebrand this is said to be largely due, as he was one of the first to introduce foreign ornamental plants, and his place, which is kept much as it was at the time he left the islands, was a very remarkable collection of useful and ornamental plants from the warm regions of almost the whole globe.

Probably the first thing that strikes the traveller from the cooler regions is the great variety and number of palms. Of these the beautiful royal palm (*Oreodoxa regia*) is easily first. With its smooth columnar trunk, looking as if it had been turned, encircled with regular ring-shaped leaf-scars, and its crown of plumy green leaves, it well deserves its name. Other characteristic palms are various species of betel palms (Areca), wine palm (Caryota), sugar palm (Arenga), and a great variety of fan-palms of different genera. None is more beautiful than a thrifty young cocoa palm, but unfortunately it is very subject in the Hawaiian Islands to the ravages of some insect which eats the leaves and often renders them brown and unsightly. Indeed, it is almost impossible to find a specimen which is not more or less disfigured by this pest. The trunk of the cocoanut tree is usually more or less crooked, and in old specimens much too tall for its thickness, so that the old trees look top-heavy. The date palm flourishes in Honolulu, where it is quite dry, but does not do so well in the wetter parts of the islands.

On studying the other trees, one is struck at once by the great preponderance of Leguminosæ, especially Cæsalpineæ and Mimoseæ. All about the town, and growing very rapidly, is the algaroba (*Prosopis juliflora*), a very graceful tree of rapid growth, with fine bipinnate leaves and sweetish yellow pods, which animals are very fond of, and which are used extensively for fodder. Add to this that the tree now forms the principal supply of fuel for Honolulu and we can realize its full value. Other leguminous trees that are planted are the monkey-pod (*Pithecolobium samang*), tamarind, various species of Bauhinia and Cathartocarpus. One species of the latter with great drooping bunches of golden yellow flowers and enormous cylindrical pods three or four feet long, rivals the Poinciana when in full flower.

Mingled with these are a great number of shrubs and trees with showy flowers or leaves, most of them more or less familiar to the stranger, either from pictures or from green-house specimens. Several species of Musa are grown, and when sheltered from the wind are most beautiful; but ordinarily the leaves are torn into rags by the wind. The tall and graceful *M. sapientium* has been largely supplanted by the much less beatiful Chinese banana, *M. Cavendishii*, which is short and stumpy in growth, but enormously prolific. The related traveller's tree (*Ravenala Madagascariensis*), is a common and striking feature of many Hawaiian gardens. Of the many showy flowering shrubs, the beautiful *Hibiscus Rosa-Sinensis* is one of the commonest, and is used extensively for hedges. One of the most striking hedges in the city, however, is the famous one at Puna Hou college, which is 500 feet long and composed of night-blooming cereus. I was not fortunate enough to see this when it was in full flower, but I saw a photograph of it when it was estimated that there were about 8000 flowers at one time.

Of the fruit trees ordinarily grown, the following may be mentioned. The mango is a very handsome tree with dense dark green foliage and masses of yellow and reddish fruit on long hanging stalks. The bread-fruit tree is common, both cultivated and wild, and is a very beautiful tree of moderate size, with leaves looking like immense fig-leaves, and the fruit like a large osage orange. I saw no ripe fruit, and so had not an opportunity of testing its quality. Guavas of different varieties are extremely common, both wild and cultivated, and the various fruits of the whole citrus tribe grow well. The few specimens of temperate fruits were, for the most part, much inferior to those of the United States. Of the fruits that did not strike my fancy, at least at first, was the alligator pear (*Persea gratissima*), a big green or purple pear-shaped fruit with an immense single seed. The pulp is somewhat waxy in consistence and very oily. It is eaten as a salad, and very much relished by the islanders, but the taste is acquired. The curious papaya (*Carica papaya*) is another fruit which did not appeal to my palate. Its big orange fruit, not unlike a melon in appearance when cut open. has a peculiar "squashy" flavour that suggested it having been kept a day too long.

Many showy climbers are planted, some of which, like Stephanotis, Thunbergia and Allamanda are superb; but there is one that is particularly obnoxious in colour, Bougainvillea, whose magenta floral-bracts are an offence to the eye, forming a cataract of raw colour. It looks, as some one observed, as if it had just come from a chemical bath.

As soon as one gets fairly away from the city, it is at once seen that all the luxuriant vegetation is strange. Along the seashore is a plain gradually rising into low hills, both almost destitute of trees, except here and there a few cocoa palms along the shore. Of the strictly littoral plants among the most conspicuous is the curious *Ipomœa pes-capræ*, with deeply two-cleft leaves and purplish pink flowers. In the fertile lowlands near the sea are the principal cane and rice fields, which with taro are the staple crops. The rice is cultivated entirely by Chinese, near Honolulu; but on the sugar plantations the Japanese are largely employed. To see a Chinese laboriously transplanting little handfuls of rice into straight rows, or ploughing in the mud and water with a primitive plough drawn by a queer Chinese buffalo are sights very foreign to an American eye. Sugar cane is eminently productive in the islands, and, hitherto, has proved the main source of revenue; but now the Hawaiians are bewailing the depression caused by the free admission of sugar from other countries into the United States; as, hitherto, their product has enjoyed practically a monopoly of the American market, having been admitted by treaty free of duty.

I made several trips up the valleys back of the city, but owing to the almost constant rain in many of them, these were not always agreeable. However, one is richly repaid by the luxuriance and variety of the vegetation. For a mile or two we pass between grass-covered hills, or hills overgrown in places with the lantana, which, introduced as an ornamental plant, has become a great pest. This plant covers some of the hills with an absolutely impassable thicket, and spreads very rapidly, so that it is a serious problem what is to be done with it. Of the common roadside plants, an orange and yellow milkweed and the showy white *Argemone Mexicana* were the most conspicuous. As one proceeds farther, where more moisture prevails, the variety becomes larger. Thickets of Canna and a Clerodendron with double rosy-white flowers, are common, and the curious screw-pine (*Pandanus odoratissimus*) is occasionally seen. This latter is a very characteristic plant, but is much more abundant in some of the other islands. In this region some very showy species of Ipomœa are very common, among them the well-known moon-flower, *I. bona-nox*.

With the increase in moisture, as might be expected, the mosses and ferns increase in number and beauty. There are many of them of types quite different from those of the United States. One of the commonest ferns of the lower elevation in *Microlepia tenuifolia*, a very graceful fern with finely divided leaves and terminal sori. Species of Vittaria, with very long undivided leaves, are also common here.

As we ascend one of the commonest ferns is *Sadleria cyatheoides*, a very large fern, often more or less arborescent. Ascending still higher the number and variety of ferns increases rapidly, and many beautiful and interesting ferns and mosses and liverworts become common.

At about one thousand feet elevation we begin to meet with species of Cibotium, to which genus belong the largest of the tree ferns of the islands. Here, also, I met for the first time with the smallest of all the ferns I have ever seen, *Trichomanes pusillum*. This dainty little fern, one of the Hymenophyllaceæ, forms dense mats on rocks and tree-trunks, looking like a delicate moss. The full-grown frond is fan shaped, and, with its stalk, is not more than half an inch high. These tiny leaves, nevertheless, in many cases bore sporangia.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 8.—"Preliminary Account of the Nephridia and Body Cavity of the Larva of *Palæmonetes varians*." By Edgar J. Allen, B.Sc., University College, London. Communicated by Prof. W. F. R. Weldon, F.R.S.

The Green Gland, in a larva of *Palæmonetes* which is a few days old, consists of an end-sac, which communicates by means of a U-shaped tube with a very short ureter, opening at the base of the second antenna. At the time of hatching, the gland consists of a solid mass of cells, without a lumen. In later stages the tube of the gland enlarges to form the bladder. The enlarged bladders of the two sides subsequently meet and fuse in the middle dorsal line, forming the nephroperitoneal sac described by Weldon and Marchal.

The Shell Gland is found in late embryos and young larvæ of *Palæmonetes*. It consists of a short renal tube, with a considerable lumen, which communicates internally with an end-sac, and opens externally at the base of the second maxilla.

Sections through the anterior region of the thorax of *Palæmonetes* show that the body cavity may be divided into four regions: a *dorsal sac*, surrounded by a definite epithelium, in which the cephalic aorta lies, but which does not itself contain blood; a *central cavity*, containing liver, intestine, and nerve-cord; two *lateral cavities*, containing the proximal ends of the shell glands; and fourthly, the *cavities of the limbs*, which contain the distal ends of the same organs.

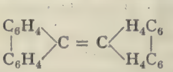
In late embryos of *Palæmonetes* solid masses of cells lie upon either side of the cephalic aorta. The dorsal sac is formed by the hollowing out of these masses of cells. Two lateral cavities are thus formed, which are separated by the aorta. The protoplasm of the cells lining these cavities, which is at first gathered into masses around the nuclei, then spreads out into a thin sheet, drawing away from the lower portion of the aorta, and causing the two lateral cavities to unite ventrally, and so form a single sac.

In the posterior region of the thorax the central and lateral cavities are similar to those of the anterior region, whilst dorsal to them the pericardial chamber lies. This chamber is separated from the central body cavity by the pericardial septum. The genital organs are situated immediately below the front end of this septum.

A comparison with the body cavity of *Peripatus* suggests the following relations. In the anterior region of the thorax of *Palæmonetes* the dorsal sac is homologous with the dorsal portions of the mesoblastic somites of *Peripatus*, and its cavity is a true cœlom. The central and lateral cavities, together with the cavities of the legs, represent the pseudocœle. In the posterior region of the thorax the cavities are all pseudocœlomic, and agree with those of the adult *Peripatus*.

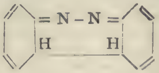
December 15.—"Preliminary Note on the Relation of the Ungual Corium to the Periosteum of the Ungual Phalanx." By F. A. Dixey, M.A., M.D., Fellow of Wadham College, Oxford. Communicated by E. A. Schäfer, F.R.S.

Chemical Society, December 1.—Prof. A. Crum Brown, President, in the chair.—The following papers were read:—The isolation of two predicted hydrates of nitric acid, by S. U. Pickering. The author announces the isolation of two crystalline hydrates of nitric acid: the monohydrate and the trihydrate, melting at − 36·8° and − 18·2° degrees respectively. In the case of either the melting-point is lowered by the addition of acid or water. The existence of these compounds was foreseen from an examination of the curves plotted from Bertholet and Thomsen's heat of dissolution values. This result is an important confirmation of the author's views.—Anhydrous oxalic acid, by W. W. Fisher. The best method of obtaining crystallized anhydrous oxalic acid is by allowing the hydrated acid to remain in contact with concentrated sulphuric acid for some months in a sealed glass tube. Oxalic acid is soluble in about 30 parts of cold sulphuric acid; the anhydrous acid dissolves with absorption of heat, whilst the reverse is the case with the hydrated acid. Anhydrous oxalic acid may be crystallized from nitric acid of sp. gr. 1·5. Oxalic acid may be completely dehydrated in a vacuum at 60°; the anhydrous acid is soluble in ethyl oxalate or glacial acetic acid, and separates from these solvents in a powdery form.—The production of orcinol and other condensation products from dehydracetic "acid," by N. Collie and W. S. Myers. The authors have obtained orcinol by the action of barium hydrate on dehydracetic "acid" or dimethylpyrone; on boiling a mixture of syrupy caustic soda and dehydracetic "acid," a true carboxylic acid is first produced, and, losing carbonic anhydride, yields orcinol. Among the products of the interaction of barium hydrate and diacetylacetone bright yellow needles melting at 180–181° are found; these probably consist of a naphthalene derivative $C_{11}H_{14}O_3$. Amidodehydracetic "acid," obtained in long needles melting at 192–196°, by the action of strong ammonium hydrate on dehydracetic "acid," readily yields dehydracetic "acid," on acid or alkaline hydrolysis.—Observations on the origin of colour and on fluorescence, by W. N. Hartley. It cannot be stated in general terms that colour is due to special methods of atomic arrangement; the statement may, however, be applied in a restricted sense to certain organic compounds, especially to those included in the class to which organic dye-stuffs belong. It is pointed out that all open chain hydrocarbons exert a continuous absorption, the extent of which depends on the number of carbon atoms in the molecule. The condition of strain and instability existing in many coloured substances has been remarked by Armstrong; the author points out that all organic colouring matters are endothermic compounds, and considers this to be the physical cause of what Armstrong terms "reactivity" or "high potential." It is shown that anthracene is not colourless, but has a true greenish-yellow colour in addition to its fluorescence. A number of experiments on fluorescence are detailed, and the following conclusions drawn from them:—(1) Alcoholic solutions of quinine exhibit a beautiful, bright violet fluorescence. (2) Hydrochloric acid is not fluorescent. (3 and 4) Quinine hydrochloride and chloroform are feebly fluorescent, but without distinct colour. (5) Both hydrochloric acid and chloroform can extinguish those rays which are the cause of fluorescence in quinine. (6) Some alkaloids may be recognized by the degree and colour of their fluorescence. (7) Normal alcohols of the ethylic series and the fatty acids are fluorescent. (8) Glycerol has a violet fluorescence. (9) Benzene has a pale blue fluorescence, azobenzene a greenish-blue. (10) Rock crystal has a pale bluish-violet fluorescence, flint glass a strong blue, and crown glass a very brilliant blue fluorescence. (11) Substances which are not fluorescent in strong solutions may become so on dilution, particularly if they exert a very powerful absorption of the ultra-violet or invisible spectrum.—The origin of colour, v. coloured hydrocarbons and fluorescence: a reply to Prof. Hartley's observations on the origin of colour and of fluorescence, by H. E. Armstrong. If attention be paid to visibly-coloured organic substances, it is a most remarkable fact that in those cases in which the "constitution" is fairly well established coloured substances are found to be all of one type. The author starts from this basis to inquire whether all coloured organic substances are not similar in type. Hartley's remark that all organic colouring matters are endothermic compounds has little importance in the present connection, inasmuch as the converse does not hold. The author contends that before admitting the fluorescence of many substances, *e.g.* alcohol and its homologues, every precaution must be taken to ensure their purity; instances in which easy explanation of the fluorescence of certain substances is possible are given. Hartley's observation that anthracene is coloured strongly confirms the author's hypothesis. Anthracene is fluorescent, and may be represented by a quinonoid formula, whilst its isomeride phenanthrene, which cannot be so represented, is colourless and non-fluorescent. Furthermore, whilst intense colour is produced by "weighting" what the author terms the "quinonoid radicles" of anthracene by replacing the central hydrogen atoms by a halogen, no such effect attends the similar treatment of phenanthrene, dibromophenanthrene being colourless like the hydrocarbon. And yet anthraquinone and phenanthraquinone are coloured yellow and deep orange respectively. Reference is made to other coloured hydrocarbons, viz. carotin and the red hydrocarbon, $C_{26}H_{16}$, recently investigated by Graebe. The formula assigned to the latter by Graebe—



$$\begin{matrix} C_6H_4 \\ | \\ C_6H_4 \end{matrix} \!\!>\! C = C \!<\!\! \begin{matrix} H_4C_6 \\ | \\ H_4C_6 \end{matrix}$$

—is an improbable one; such a substance would be colourless. The author gives a possible constitution, and, for the present, proposes to call the compound "erythrophene." The yellow hydrocarbon, $C_{26}H_{16}$, obtained together with this, is possibly a diphenylated anthracene, and may be termed "xanthophene." The "quinonoid radicles" in both hydrocarbons are heavily "weighted," hence their strong colour. With reference to Hartley's statement that a very little shifting of the region of absorption determines the presence or absence of colour in a compound, it is contended that this shifting may be due to a special character of structure. The author then explains his views as to the manner in which the "quinonoid mechanism" conditions colour. He suggests that in quinonoid compounds there are two "colour centres" corresponding to and expressed by the symbol $\overset{\frown}{\smile}$ in formulæ such as he has used in representing coloured substances. These centres co-operate in producing colour through interaction of the light waves which traverse them. Substances in which there are no such co-operating centres may absorb generally and selectively in "ultra" or "infra" regions of the spectrum, but without exhibiting "visible colour."—The origin of colour, vi. azobenzene, by H. E. Armstrong. Azobenzene, a highly-coloured substance, is generally represented as Ph.N : N.Ph, a formula in disaccord with the author's hypothesis explained in the preceding paper. Moreover, the formulæ usually attributed to the colourless diazo-salts (Ph.N : N.Cl, for example) represent them as comparable in constitution with azobenzene. The behaviour of azobenzene towards bromine and other reagents leads the author to doubt the correctness of the conventional formula assigned to it, and to consider the following a more probable one:—



—The reduction products of dimethyldiacetylpentane, by F. S. Kipping. The author shows that dimethyldiacetylpentane, a diketone produced by the hydrolysis of ethyl dimethyldiacetylpimelate is converted by reduction with sodium in a moist ethereal solution into dimethyldihydroxynonane and a compound which, judging from the manner in which it is formed, may be regarded as tetramethyldihydroxyheptamethylene.

$$CH_2\left\langle\begin{array}{l}CH_2\,.\,CHMe\,.\,CMe\,.\,OH\\ \qquad\qquad\qquad\quad |\\ CH_2\,.\,CHMe\,.\,CMe\,.\,OH\end{array}\right..$$

—The products of the interaction of zinc chloride or sulphuric acid and camphor (third notice), by H. E. Armstrong and F. S. Kipping. The authors have previously shown that the crude product obtained on heating camphor with sulphuric acid or zinc chloride contains 1 : 2 : 4 acetylorthoxylene. On oxidizing the oil remaining after the separation of the latter substance, α-methylglutaric acid is formed. This acid being the characteristic oxidation product of the phorone obtained by distilling calcium camphorate, it is probable that a homologue of this phorone is present in the camphor product.—The Griess-Sandmeyer interactions and Gattermann's modification thereof, by H. E. Armstrong and W. P. Wynne. In employing the Griess-Sandmeyer methods for displacing the amido-group by halogens, the authors find that, in very many cases, much better results may be obtained by operating at relatively low temperatures instead of at the boiling point. It appears also that the Gattermann process affords a larger yield than the Sandmeyer process, only because it is carried out at a lower temperature.—Methods of observing the spectra of easily volatile metals and their salts, and of separating their spectra from those of the alkaline earths, by W. N. Hartley. Persistent flame colourations of easily volatile metals, such as lithium, potassium, rubidium, cæsium, and thallium, may be obtained by heating beads of their fluosilicates, borates or silicates, on platinum wires in the Bunsen flame. If the substance to be spectroscopically examined be converted into a borate, the spectra of the alkali metals may be first observed, and on subsequently passing hydrogen chloride into the flame, the spectra of the alkaline earth metals may be rendered visible.—Manganese borate, its constitution and properties, by W. N. Hartley and H. Ramage. Manganese borate, after drying *in vacuo* over sulphuric acid has the composition $MnH_4(BO_3)_2.H_2O$. On heating at 100° it loses one molecule of water, and at a red heat two molecules more of water are lost, leaving a salt of the composition $Mn(BO_2)_2$. From the rate of loss of water with rise of temperature the existence of a number of intermediate salts is inferred. Manganese borate possesses a maximum of solubility in water at 18°, and a minimum at 80°. This is probably due to dehydration of the compound having the composition $MnH_4(BO_3)_2.H_2O$.

Anthropological Institute, December 13.—Edward B. Tylor, President, in the chair.—Mr. Arthur J. Evans read a paper on the prehistoric interments of the Bahi Rossi caves near Mentone and their relation to the Neolithic cave-burials of the Finalese. He described the recent discovery of three skeletons in the cave of Barma Grande, and showed that the character of the sepulchral rites practised, the relics found, and the racial type of the human remains agreed with the earlier discoveries made by M. Rivière and others in the same caves. Mr. Evans, however, opposed the theories that had been put forward as to the Palæolithic date of "Mentone Man." The bones of extinct Pleistocene animals and implements of the Moustier and Magdalenian types found in the cave earth above the interments proved nothing, for the simple reason that they were interments. No remains of extinct animals had been found in actual juxtaposition with the skeletons. On the other hand the complete absence of pottery, of polished implements, and of bones of domesticated animals in this whole group of interments and the great depth at which they occurred proved that the remains belonged to a very early period. Evidence was here supplied of an earlier Neolithic stage than any yet authenticated. Still the remains belonged to the Later Stone Age and to the days of a recent fauna. Mr. Evans compared some bone ornaments found with the so-called hammer-heads of the chambered barrows of Scandinavia and the decorative system with that found on Neolithic pottery in northern Europe. He further showed that interments of the same tall dolichocephalic race in a more advanced stage of Neolithic culture were to be found in the cave-burials of the Finale district further up the Ligurian Coast. The physical form and the character of the sepulchral rites was essentially the same. Only the skeletons were here associated with polished axes, pottery, and bones of domesticated animals. The direction from which the new civilizing influences had come was indicated by imported shell ornaments from the southern and eastern Mediterranean; in the Mentone caves the imported shells were from the Atlantic. In conclusion Mr. Evans showed that the latter Finale interments exhibited forms of pottery and implements identical with those of the Italian terremare of the other side of the Apennines, and included ceramic shapes which seemed to be the prototypes of vessels found in the early Sikel tombs of Mycenæan age. The Italic culture here revealed fitted on not only to that of the early pile-settlements of the Po Valley and the Lake-dwellings of Switzerland, but might be traced to the Danube valley, to Thrace, and the Troad. Amongst other parallel forms owl-like idols bearing a strong resemblance to those described by Dr. Schliemann from the site of Troy had been found by Padre Morelli of Genoa in one of the Finale caves.—Dr. H. Colley March read a paper in which he sought to prove that the peculiar features of Polynesian ornament are due to a mythography which is, in the main, a symbolism of origin and descent. Thus regarded, unattractive and bewildering designs are resolved into emblems of divinity and demonstrations of lineage. He traced the evolution and defined the attributes of Tiki, explained the nature of oromatuas and the meaning of unus, described the various methods of recording pedigrees, whether along a male or along a female line, and illustrated the mythical use of tapa and sinnet. He discussed, as modes of origin, totemism, gemmation, and generation, of which Polynesian examples were given, tabulated the kinship of the superior gods, set forth in full the Tane cult, especially in relation to the axe and the drum, and endeavoured, in conclusion, to account for the development of the complicated Mangaian adze.

EDINBURGH.

Royal Society, December 5.—Sir Douglas Maclagan, President, in the chair.—After an introductory address by the President, a note by Prof. Cayley, on uniform convergency of series, was read.—Prof. Tait communicated a note by Prof. P. H. Schoute, of Groningen, on the locus of a uniformly revolving line, which always passes through a point moving uniformly round a circle, and which always lies in a normal plane passing through the centre of that circle. The degree of the locus is found by an elegant and very simple method.—Dr. C. Hunter Stewart gave notice of a paper on the further development of Kjeldahl's method of organic analysis. The carbon, as well as the nitrogen, present can be determined by the same analysis in the developed method, and much smaller quantities than formerly of the substance analyzed lead to results as accurate as those previously obtained.—Prof. Tait read a note on the division of space into cubes. He gives a different, and more direct and short, solution by quaternions than that given by him some years ago.

PARIS.

Academy of Sciences, December 26.—M. d'Abbadie in the chair.—Thermal elevation under the influence of injections of soluble microbian products, by MM. Bouchard and Charrin. An elevation of temperature recalling that observed by Koch is produced in a marked degree in tuberculous patients by injections of the toxic substances secreted by the pyocyanic bacillus.—Vessels and clasmocytes of the hyaloid in the frog, by M. Ranvier.—Observations of Holmes's comet (November 6, 1892) made with the great equatorial of the Bordeaux Observatory, by MM. G. Rayet and L. Picart, report by M. Rayet.—Observations of Swift's comet (1892, I.) made with the great equatorial of the Bordeaux Observatory, by MM. G. Rayet, L. Picart and F. Courty, report by M. Rayet.—On the laws of dilatation of fluids at constant volume; coefficients of pressure, by M. E. H. Amagat.—Observations of Holmes's comet, made with the *equatorial coudé* (32 cm.) of the Lyon Observatory, by M. G. Le Cadet.—New experimental researches on the personal equation in transit observations, by M. P. Stroobant.—On conjugate systems and couples of applicable surfaces, by M. A. Petot.—On infinitesimal deformation and Bianchi's associated surfaces, by M. E. Cosserat.—On contiguous surfaces relative to the hypergeometrical series with two variables, by M. Levavasseur.—Test for the convergence of series, by M. A. de Saint-Germain.—Criterion of divisibility by any number, by M. Fontés.—On the motion of a particle in the case of a resistance proportional to the velocity, by M. Elliott.—General form of the law of vibratory motion in an isotropic medium, by M. E. Mercadier.—Employment of springs in the measurement of explosive pressures. If errors due to the inertia of the moving parts of the indicator are to be avoided, the amplitude of the tracing point must not exceed 1 mm. in the case of pressures used in modern firearms. This necessitates careful reading with a microscope.—On the decrease of temperature of the air with the elevation, by M. Alfred Angot. Experiments conducted on the Eiffel Tower indicate a decrease for each 100 m., between the soil and a height of 160 m., ranging from 0·6° in December to 1·46° in June. Between 160 m. and 302 m. the decrease per 100 m. ranges from 0·64° in February to 0·96° in October. At 300 m. the decrease per 100 m. is on the average 0·5° in winter, 0·6° in autumn, 0·7° in spring, and 0·8° in summer.—On the temperature of the electric arc, by M. J. Violle. From calorimetric measurements made with a portion of the arc light carbon detached from the hottest part during the passage of the current, the temperature of the arc, *i.e.* that of the volatilization of carbon, appears as 3500°, assuming the carbon to have its theoretical specific heat, 0·52, at the higher temperatures. This temperature of volatilization is constant, whatever the power employed.—Remarks on high temperatures and the vaporization of carbon, by M. Berthelot. The vapour tension of carbon is quite appreciable even below volatilization, which involves the reduction of a polymer to the monomolecular state, thus in reality representing a chemical process. Higher temperatures than that of the arc can be attained by purely chemical means, such as the explosive combustion of a mixture of oxygen and cyanogen.—On the equality of velocities of propagation of electric waves in air and along conducting fibres, verified by the example of a large metallic surface, by MM. Ed. Sarasin and L. de la Rive.—On nets of electric conductors; reciprocal properties of two branches, by M. Vaschy.—On the enfeeblement of electromagnetic oscillations with their propagation and their subsidence, by M. A. Perot.—Determination of the coefficients of self-induction by means of electrical oscillations, by M. P. Janet.—Doppler-Fizeau's method, exact and approximate formulæ, evaluation of the error involved, by H. de la Fresnaye.—Magnetic properties of oxygen at different temperatures, by M. P. Curie. A series of measurements with oxygen compressed to 5 and to 18 atmospheres respectively gave identical results at temperatures between 20° and 450°. Within this range, the volume coefficient of specific magnetization of oxygen varied inversely as the absolute temperature. The volume coefficient of magnetization of air at the ordinary pressure and at temperature t is given by $10^6 k_t = 2760 \times T^{-2}$, where T is the absolute temperature.—On the rotatory power of quartz at low temperatures, by MM. Ch. Soret and C. E. Guye.—On the fusion of carbonate of lime, by M. A. Joannis.—Ammoniacal compounds derived from ruthenium sesquichloride, by M. A. Joly.—On an iodo-sulphide of phosphorus, by M. L. Ouvrard.—Action of bismuth on hydrochloric acid, by MM. A. Ditte and R. Metzner.—Action of potash and soda on the oxide of antimony, by M. H. Cormimbœuf.—Relation between the heats of formation and the temperatures of the point of reaction, by M. Maurice Prud'homme.—On the study of the chemical reactions in a liquid mass by the index of refraction, by M. C. Féry.—On a propylamidophenol and its acetyl derivatives, by M. P. Cazeneuve.—Quantitative determination of impurities in the methylenes, by M. Er. Barillot.—Separation of micro-organisms by centrifugal force, by M. R. Lezé.—Loss of nitrogen in manures, by MM. A. Müntz and A. Ch. Girard.—Fermentation of manure, by M. A. Hébert.—Drying-up of marshes in Russia, by M. Venukoff.—Chemical conditions of the action of ferments, by M. J. Effront.—On trichophytia in man, by M. R. Sabouraud.—Evolution of the functions of the stomach, by M. J. Winter.—On the histology of the organs attached to the male apparatus in *Periplaneta orientalis*, by M. P. Blatter.—On the presence of a fossil Araliacea and Pontederiacea in the coarse Parisian limestone, by M. Ed. Bureau.—On a new geological map of the French and Spanish Pyrenees, by MM. Emm. de Margerie and Fr. Schrader.—Differential motion of the ocean and the atmosphere; water tides and air tides, by M. F. de Saintignon.—On the perforation of the basaltic rocks of the Gulf of Aden by shingle; formation of a Giant's Kettle, by M. Jousseaume.

AMERICAN MECHANISM.

Modern Mechanism. Edited by Park Benjamin, LL.B., Ph.D. (London and New York: Macmillan and Co., 1892.)

IN order to appreciate this volume thoroughly, it is necessary in the first instance to consider the reason for its existence. Appleton's "Dictionary of Engineering," an American book, was published in the year 1851, and was the first to gather in cyclopedic form descriptions of products of American mechanical industry. Some thirty years afterwards it became necessary to bring the work up to date, and its complete reconstruction was decided upon. The editor observes that no previous work of a technical character had so signally, and so quickly, demonstrated its own usefulness; it rapidly became a recognized standard of American mechanical practice. Owing, however, to the great progress made in mechanical invention, and the marvellous rapidity with which electrical science has advanced, a new record of the results has become necessary, and hence the present volume.

The list of contributors includes the names of eminent men, well known in this country for their high attainments in the different branches of mechanical and electrical engineering, forming a sure guarantee that the information to be gleaned from the pages is valuable and accurate. It would be impossible in the space at our disposal to notice more than a small part of the contents. Some interesting information is to be found on the subject of aerial navigation, more particularly the interesting experiments being carried out by Mr. Hiram S. Maxim. Commenting on Prof. Langley's statement, that with a flying machine the greater the speed the less would be the power required, Mr. Maxim says: "In navigating the air we may reason as follows: if we make no allowance for skin friction and the resistance of the wires and framework passing through the air—these factors being very small indeed at moderate speeds as compared to the resistance offered by the aëroplane—we may assume that with a plane set at an angle of 1 in 10, and with the whole apparatus weighing 4000 pounds, the push of the screw would have to be 400 pounds. Suppose, now, that the speed should be 30 miles an hour; the energy required from the engine in useful effect on the machine would be 32 horse-power (30 miles = 2640 feet per minute, $\frac{2640 \times 400}{33,000} = 32$). Adding 20 per cent. for slip of screw, it would be 38·4 horse-power. Suppose, now, that we should increase the speed of the machine to 60 miles an hour, we could reduce the angle of the plane to 1 in 40, instead of 1 in 10, because the lifting power of a plane has been found to increase in proportion to the square of its velocity. A plane travelling through the air at the rate of 60 miles an hour, placed at an angle of 1 in 40, will lift the same as when placed at 1 in 10, and travelling at half this speed. The push of the screw would therefore have to be only 100 pounds, and it would require 16 horse-power in useful effect to drive the plane. Adding 10 per cent. for the slip of the screw, instead of 20, as for the lower speed, would increase the engine power required to 17·6 horse-power. These figures, of course, make no allowance for any loss by atmospheric friction. Suppose 10 per cent. to be consumed in atmospheric resistance when the complete machine was moving 30 miles an hour, it would then require 42·2 horse-power to drive it. Therefore at 30 miles an hour only 3·84 horse-power would be consumed by atmospheric friction, while with a speed of 60 miles an hour the engine power required to overcome this resistance would increase eightfold, or 30·7 horse-power, which, added to 17·6, would make 48·1 horse-power for 60 miles an hour."

Mr. Maxim goes on to observe that his experiments show that as much as 133 pounds can be carried with the expenditure of 1 horse-power, and under certain conditions as much as 250 pounds. It will be evident, therefore, that the question of motors is all important, and that the total weight per horse-power developed must be as low as possible. It is stated that the greatest force can be obtained from a compound high-pressure steam engine using steam at 200 to 350 pounds pressure, and such engines have been constructed weighing 300 pounds; the horse-power of these engines is not stated.

It will be interesting to watch the outcome of these investigations. They indicate that much information is being accumulated, and that sooner or later a successful aerial machine will be forthcoming.

The question of armour plates has long vexed the soul of the British Admiralty; many very costly trials have been carried out in order to find the most suitable plate for the service. All these data have probably been known in the States, and that country must have benefited by them. Under this heading we find much information in the book, American experiments being quoted and illustrated. Naturally, the Americans wish to make their own plates, and wisely endeavour to do so by rolling only, to do without the heavy expense of forging. These experiments show that the high-carbon nickel Harveyed plate is undoubtedly the best plate ever tested. As a result of these trials, orders have been placed for plates for the cruisers under construction. An excellent full-page engraving is given of the U.S. armoured battle ship *Indiana*, and to judge by the blackness of the smoke she is not using Welsh coal! The article on steam boilers is well written, and very complete, containing much useful information. Among the many types of boilers illustrated there is a good print of the Yarrow torpedo boat boiler. We miss, however, the familiar Thornycroft boiler, and note an American water tube-boiler for fast launches very like the Thornycroft in the arrangement of the tubes.

The boilers for marine purposes are purely of the British type, and there is nothing of importance to note on this subject beyond the many experimental results recorded.

Further on in the book there is an interesting description of railway-car heating. We are told that car-heating, in the usual acceptance of the term, has come to mean the heating of railway cars by the use of steam from the locomotive. This is important, showing as it does the direction in which American railway companies are moving in the solution of a problem at present occupying the best attention of engineers in this country. Generally, we are told, the systems consist of a separate hot-water circulating system in each car, in connection with a heater, fed by steam from the locomotive, by a continuous train pipe running the length of the train, and coupled together between the cars by flexible hose-pipes and universal couplings; the Sewall steam coupler being generally used. Another important railway necessity is the continuous brake. Under this heading the latest form of Westinghouse quick-action automatic brake is described. In the original design the brake is applied by the engine-driver allowing a little air to escape from the train pipe, lowering the pressure, and thus applying the brake by the automatic action of the triple valves. It is evident that the vehicle next the engine will feel this reduction first, and its triple valve will work before that on the second vehicle, and so on. On trains of ordinary length this very slight difference in time between the brake's application on each vehicle is of little consequence, but when this automatic brake is fitted to a long goods train it becomes a serious matter. The length of a goods train of fifty American cars is 1900 feet, and the brake should act instantaneously to be perfect. The new triple valve is itself designed to discharge air from the train pipe; so on the driver opening the driver's valve, allowing air to escape to apply the brakes, the reduction of pressure operates the triple valve on the first car; this lets out more air, and so on through the train, the brake on the last car, 1900 feet away, being operated in 2·5 seconds after that on the first car.

The vacuum automatic brake is not described or illustrated. This brake is now being more and more brought into use and for general purposes it appears to be simpler and less liable to get out of order than its competitors.

A considerable part of the volume is taken up with the applications of electricity, for lighting and motive power purposes generally. On dynamo electric machinery much has been written and well illustrated. The reader is taken step by step from the rudiments of the subject to its latest applications, from a description of armatures to the arrangements of the field-magnets, then to the varying designs of dynamos, including most of the known machines. The same may be said on the treatment of the electric motors. Under the head of the transmission of power there is more useful information to be found, this being all the more interesting, because of the proposed use of electricity as a means of transmitting some of the power of Niagara to distant towns. There is, however, something wanting under the heading of electrical measuring instruments. The only ones mentioned are Weston's volt and ammeters. At the present time the street tramways of this country are in an uncertain stage as far as motive power is concerned; horse-power is admittedly expensive; the steam locomotive seems to have got into disrepute; the cable and electric traction appear to be struggling for the mastery. It is interesting therefore to read the memoir on electric traction in this volume. The accumulator system is just described, but the overhead cable or trolley system takes up the greater part of the space, so it is safe to assume that the latter is more generally in use, the principle of which is as follows: the current starts from the positive brush of the dynamo, passing out to the main conductor, suspended over the middle of the track, and along this conductor until it reaches the point where the trolley of one of the motor cars is in contact. Here it divides, and a portion passes down through the trolley to the motors, and thence to the rails forming a return lead to the negative brush of the generator. The main portion of the current passes on to feed other cars upon the line in the same manner, each car taking the quantity of current necessary to develop the required power. There are at the present time nearly 500 electric railways in America, and taking the results of twenty-two electric trolley lines, we find that the expenses vary per car mile from 22·99 cents to 7·89 cents, the highest and lowest respectively. A view is given of the electric street railway at Washington, D.C.; the overhead conductors being not at all unsightly.

On electric welding there is also much information, the Thomson process being very fully described. It consists briefly in completing the electrical circuit through the parts to be welded together, the resistance being sufficient to heat the parts so as to weld them, this being assisted by pressure.

The Bernado process is not described; in this process the work to be welded is connected to one terminal of the dynamo. The positive terminal being connected with a carbon rod, held in a portable insulated holder, the carbon rod is then placed on the work, and immediately withdrawn slightly, thus forming an arc, where the metal melts, and with skill much can be done.

The locomotive practice in America has long been of interest to locomotive engineers in this country, owing to the many differences in design and practice. A very good *résumé* of American practice is to be found in the memoir under this heading. A useful table is given showing a few leading dimensions, weights, &c., of typical engines in use. Take, for instance, the express passenger engine, a four-coupled bogie engine, the cylinders being 20 inches in diameter and 24 inches stroke. The driving or coupled wheels are 72 to 78 inches in diameter. The weight on coupled wheels is 75,000 pounds (33·48 tons), the total weight of the engine being 116,000 pounds (51·78 tons), and that of the tender 72,000 pounds (32·14 tons. Comparing these data, we find that the American engine is heavier than an 18×26 cylinder British engine and not so powerful, assuming equal steam pressures; the tender is light in a similar comparison, probably carrying less water. The reputed weight of trains hauled given in the table is of little use, because the speeds are not given, and for this reason comparisons cannot be made.

The paragraph on locomotive boiler construction is far too short; many interesting details might have been added. It is stated that the circular smoke-box tube plate is a conspicuous difference between the practices of the two countries, being purely American, whereas the Midland Railway Company have, amongst others, used the arrangement for some time. Owing to the enforced use of anthracite coal in certain parts, many peculiar designs of locomotive boilers have been used, the Wootten boiler being probably the most common. All, however, have particularly large grate areas, which, in the case of the Wootten, may in some cases exceed 76 square feet, or four times the area of the grate of recent British engines. An illustration is given of an engine of this type, as well as a full-page engraving of a compound locomotive with a similar boiler. This compound is very different from the Webb or Worsdell engines common in this country, being the design of the superintendent of the Baldwin Locomotive Works. The cylinders are outside the frames—there are two on each side, viz. one high-pressure and one low-pressure. The distribution of the steam being effected in each pair by one piston valve, each pair of pistons is connected to one crosshead, coupled in the usual way to the wheels.

A compound engine of the "Webb" type is also illustrated. This engine was constructed to Mr. Webb's designs in this country for the Pennsylvania Railway in 1889. It is stated that the results of experiments showed a saving of fuel over the ordinary engine of from 20 to 25 per cent.

This book is so full of interesting matter of so varied a nature that it would be possible to prolong this notice far beyond the space available. Take, for instance, agricultural machinery; the Price ploughing outfit is typical of the rest, consisting of a traction engine drawing four gangs of three ploughs, the twelve ploughs cutting eleven feet wide. The subject of milling tools is also of interest, because it is only during the last few years British engineers have used this means of shaping metals, the system having been brought into general use in the States.

Under the head of the manufacture of steel all the usual processes are described. We are informed that the Whitworth compression process is only partly successful in the formation of sound ingots; with this statement we cannot agree; the Whitworth steel ingot after compression is certainly sound throughout.

Taking into consideration the great mass of information contained in the 900 odd pages of this work, and the general excellence of the matter accumulated, it is only just to congratulate the editor on the completion of a work which must prove useful to many, and which should find a place in all technical libraries. The volume goes far to describe modern American mechanism, exhibiting the latest progress in machines, motors, and the transmission of power.

SEEDLINGS.

A Contribution to our Knowledge of Seedlings. By the Right Hon. Sir John Lubbock, Bart., M.P., F.R.S., D.C.L., LL.D., with 684 figures in text. In two volumes. (London: Kegan Paul, Trench, Trübner and Co., Ltd., 1892.)

SEEDS and seedlings have occupied the attention of Sir John Lubbock for a somewhat lengthened period. They have formed the subject of various communications, on his part, to the Journal of the Linnean Society and other publications. In the present volumes, modestly styled a "contribution," he gives us the details upon which his inferences have been founded.

The physical and chemical aspects of germination are entirely passed over, but the morphological phenomena are treated with a fulness never before attempted. The author has availed himself of the resources put at his disposal by the authorities at Kew, where the larger proportion of the seedlings described were grown expressly for the purpose. The Natural History Museum and the Cambridge Botanic Gardens have also been requisitioned, and much help has been rendered by capable assistants, whilst the services of Sir Joseph Hooker and Mr. Rendle, in looking over the proof sheets, are duly acknowledged. A work of such dimensions, crowded with detail, could hardly have been produced without such zealous co-operation. Nevertheless unity of plan and uniformity of treatment are conspicuous throughout, and thus comparison is readily effected.

Some previously published papers in the Journal of the Linnean Society, dealing with the causes which determine the form of leaves and cotyledons, are reprinted as the introduction to the treatise. The conclusion therein arrived at is that the form of the embryo, and especially that of the cotyledons, is essentially influenced by the form of the seed. On p. 78 the author begins the detailed examination of seedlings taken from almost all the orders of flowering plants. Five hundred and thirty succeeding pages in the first volume, and five hundred and eighty-eight in the second volume, are thus occupied. This little bit of statistics will serve to show the amount of detail which is contained within these volumes. The plan adopted is to give, first of all, a general sketch of the principal modifications exhibited by the fruit and seed in each order. Then follows a more detailed description of the seed and of the seedling plant in various representatives of the order. As these descriptions are identical in plan throughout, they are of great value to the student of comparative morphology. Naturally some orders are much better represented than others, but sometimes the omissions are rather unfortunate. In the genus Araucaria, for instance, seedling representatives of which are common in botanic gardens and nurseries, the diversities in the form of the seedling and in the mode of germination are very remarkable. "Characters" derived from the seedling plant have been recognized as of the highest importance for classificatory purposes since the time of John Ray (1682–1703).[1]

But whilst this is generally the case, such extraordinary exceptions as that mentioned in Araucaria are very noteworthy, and not less so because the genus in question is one of the very oldest of which fossil botanists have cognizance.

Myrtaceæ and Sapindaceæ are remarkable for the extremely diverse character of the embryo in different genera, and of which due note is taken in Sir John Lubbock's book. In Rosaceæ, on the other hand, the diversity is much less, nor is there any important morphological difference in the seedlings of the great order Compositæ, and scarcely more in Umbelliferæ, so far as they are known. These are facts of great significance with reference to the theories of inheritance and relative antiquity of groups.

---

[1] It may not be without interest to cite what Ray says on this matter:—"Floriferas dividemus in *dicotyledones* quarum semina sata binis foliis anomalis, seminalibus dictis, quæ cotyledonum usum præstant, e terra exeunt vel in binos saltem lobos dividuntur, quamvis eos supra terram foliorum specie non efferant; et *monocotyledones* quæ nec folia seminalia bina efferunt nec lobos binos conduunt." Thus Ray not only recognized the presence of one or of two cotyledons, but also their nature and their epi- or hypogeal condition. As Ray has been mentioned, it is certainly not inappropriate to allude to Grew also, for the first chapter of his "Anatomy of Plants" (1682), and the whole of the fourth book is devoted to the seeds and seedlings and in perusing them the reader will perceive that Sir John Lubbock has in a few cases been anticipated by his celebrated predecessor.

The gradual evolution of the perfect plant from the seedling is indeed a subject of great interest to the phylogenist, although it is difficult—nay, impossible—to separate those appearances which are merely hereditary from those which are the result of varying outward conditions, the more so because analogous conditions must have influenced the ancestors in past times even as they affect their successors now.

Amid such a mass of detail it is difficult to pick out points worthy of special note. We select two only out of many scores that might be mentioned. Some Onagrads are remarkable for the intercalary growth which takes place in the cotyledons, of which several illustrations are given in Sir John Lubbock's book. They call to mind the experiments of the late Prof. Dickie, who, by suppressing the plumule of seedling castor-oil plants, succeeded in inducing the cotyledons to continue their growth and to assume dimensions much greater than that which is habitual to them.

The small tubercles on the root of *Myrica californica* (vol. ii. p. 523, Fig. 663) have, so far as we know, not previously been observed. The author compares them to those found on *Alnus cordifolia*, and it would be interesting to ascertain whether these outgrowths are caused by an organism analogous to *Schinzia alni*, as described by Woronin, or to that which induces the peculiar tubercles on the roots of Leguminosæ, recently studied by Prof. Marshall Ward.

Monocotyledons generally have been rather badly treated by the author, although such genera as Potamogeton, Aponogeton, Orontium, and other Aroids, and Palms (of which not a single illustration is given) would have furnished examples at once interesting and easily accessible.

The work includes nearly seven hundred illustrations, faithfully executed, and very valuable to the student. The bibliography, in spite of its occupying no fewer than thirty-eight pages, is the weak part of the book. Some of the most important references are omitted, and whole series of species whose mode of germination has been recorded and sometimes figured, have been passed over. This only shows how colossal has been the task which Sir John Lubbock has set himself. We do not think the worse of the sun for having a few spots on his disc, nor are botanists at all likely to disparage this work because further research might have added a few more illustrations. As it is, it forms one of the most substantial and important contributions to botanical literature that have ever emanated from the press. It must continue to be a standard book of reference for generations, and it will, we hope, stimulate observers, according to their several opportunities, to prepare similar monographs on the various organs of plants.

MAXWELL T. MASTERS.

EPIDEMIC INFLUENZA.

Epidemic Influenza: a Study in Comparative Statistics. By F. A. Dixey, M.A., M.D. (London: Henry Frowde and H. K. Lewis, 1892.)

AFTER an epidemic disease has visited a country, when the pathologist and practical physician have had their say, there still remains the work of the statistician to be done. It is his province to sum up the results of the visitation in the clear light of hard figures, and to trace its onset and decline in mathematical curves. Such work is of value in more than one direction. It preserves for future generations a definite record of an epidemic of greater precision than the impression left on the mind of the physician: it enables a comparison to be drawn between our own experience and that of other countries: by the sifting and sorting of facts which it necessitates it may lead to the discovery of relationships with allied diseases which may prove of no small value to the pathologist.

This work has been done for influenza by Dr. Dixey in a very thorough and painstaking manner from the material collected under the supervision of the Registrar-General. It says much for the completeness of our registration system in London, that it is possible to compile from them such tables and curves as those with which we are presented in this work, nor are such materials available from any other city in Europe. The only cities whose statistics have been found by Dr. Dixey sufficiently accurate for comparison with our own are Paris and Berlin.

Dealing first with the epidemic of 1889–90, he shows in Table 1 the rise and progress of the disease in London, as indicated by the weekly returns of fatal cases, grouped according to the seven age periods adopted in the official returns. Table 2 gives us, so far as the returns of the period permit, the similar figures for the epidemic of 1847–48. The similar characters of the two epidemics are strikingly illustrated: in both we see the same extreme suddenness of rise, and the same features of decline, rapid at first, but becoming gradually slower during the succeeding months. In the next two tables are included similar figures for Paris and Berlin, and in these, and in Table 5, the author gives an analysis of the meteorological conditions accompanying the rise and fall of the epidemic in the three cities. These are of interest as showing how little influence the weather had on the course of the disease as a whole.

In the tables which follow—which are perhaps of greater interest than any of the others Dr. Dixey has compiled—the effects which influenza has exerted on the mortality from other diseases in London and other cities are shown. These effects are of two kinds: influenza may aggravate the mortality of pre-existent disease such as phthisis or heart disease, or diseases such as bronchitis or pneumonia may occur as complications of influenza and swell its death-roll. It is interesting to observe that whereas in 1847–48, which was in all respects a more fatal epidemic than that through which we have just passed, bronchitis showed the most extreme departure from the normal mortality, pneumonia holds that place in the late epidemic, while bronchitis falls into the second rank. In this connection may be mentioned a point of much interest illustrated in Tables 10, 11, and 12, which deal with the age incidence of influenza and its concomitant diseases. It is possible to draw curves showing the special age incidence of each, and each curve has its own special features. Now during an influenza epidemic the pneumonia curve is found to be modified so as to take on some of the characters of the influenza curve, thus affording corroborative evidence of a conclusion already reached both in this country and in

Germany, that influenza may occur sometimes as an apparently primary pneumonia.

The remaining tables deal with the data afforded by the epidemics of 1891 and 1892 in this country and abroad. That of 1891 is shown to have been much more fatal, especially at advanced periods of life, than that of 1890, while that of 1892, here treated of with less fulness than the preceding, seems to have been of still greater severity. Those who would follow Dr. Dixey into the details of these outbreaks must study the work for themselves. It is a contribution to statistical literature of very great value, and will save an infinity of labour to those engaged in the study of influenza.

A word of praise must be bestowed in conclusion upon the graphic charts with which the tables have been illustrated, those in particular which deal with the mortality curves from influenza and its allied diseases. These have been calculated and mapped out as percentage deviations from the mean, and show the main facts at a glance in a way which mere columns of figures fail to do. Those also which illustrate the age incidence of the diseases in question are of great value.

OUR BOOK SHELF.

An Elementary Text-Book of Hygiene. By H. Rowland Wakefield. (London: Blackie and Son, 1892.)

THE appearance of yet another elementary text-book upon the subject of Hygiene has the effect of aggravating the *embarras de richesses* which already obtains in this department of study; one is therefore justified in questioning the utility of the present volume, and on reading in the preface that it is adapted to the requirements of the Science and Art Department, there is all the more matter for surprise at its appearance in the face of three other publications—each better than the present—which have been written to meet the same end.

The manual is well printed and concisely written, and a surprising amount of matter is condensed within its tiny compass. This latter fact, however, is not entirely a matter for congratulation, for apart from making the book "dry reading," it must have the effect of rendering it in many places difficult of comprehension to those for whom it is intended, *i.e.* those who approach the subject with no prior knowledge whatever.

And thus it comes about, that in less than 200 small pages the whole range of Hygiene is surveyed, including chapters upon Eyes and Sight, School Hygiene, House Sanitation, Personal Hygiene, Parasites, Infectious Diseases, Accidents and Injuries.

Though the material given has been on the whole well selected and carefully compiled, the work is a little uneven; one finds seventy-three pages devoted to "food," whereas "water" is dismissed in seventeen, and "sewage and its removal" in eleven.

Here and there is evidence of the fact that the author is not of the profession to which Hygiene holds a filial relation, and that he was not quite at home with some of the departments of the subject—even in their elementary form—which he had set himself the task of handling; the very few errors and ambiguities which this fact is accountable for, are, however, too trivial to much affect the general accuracy of the book.

The small work will doubtless suffice for the examination requirements of those for whom it is intended, but the brevity and superficiality of treatment which is so frequently apparent within its pages, will not justify one in recommending it to those who wish to lay a good and useful foundation for a study of the science of Hygiene.

Ostwald's Klassiker der Exakten Wissenschaften. Nos. 38–40. (Leipzig: W. Engelmann.)

WE are glad to note the addition of three volumes to this admirable series. No. 38 is the second part of the original account of the photochemical researches of R. Bunsen and H. E. Roscoe (1855–59). The other volumes are translations of a paper by Pasteur on the minute organic bodies in the atmosphere (1862), and of papers by Lavoisier and Laplace on heat (1780 and 1784). In all the volumes there are figures in the text.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Geographical Names.

As the names of places given to the public with the authority of the Geographical Society of London are very apt to be accepted by geographers and be ultimately inserted in atlases and works on geography, I have to call attention to the paragraph "Nomenclature of the Karakoram Peaks," under "Geographical Notes," p. 857, in the December number of the Proceedings of the R.G.S., 1892, which I have lately read. It is to be regretted that so much reliance and importance has been placed on what a native drew on the sand, and the names he gave to various peaks. Natives are not always to be depended upon, not even when the topographical features are in sight, and unless verified from other and independent information, the names they give cannot be implicitly trusted and placed on record, as is so well exemplified in this case. The traveller must also have a considerable knowledge of the native languages or he may be very much misled. As fortunately I know both the places bearing the names given for two very conspicuous peaks, it may not be too late to prevent these names thus put forward from being accepted and perpetuated. "Skeenmung" or "Skinmang" is the name of a comparatively level piece of somewhat grassy ground at the great bifurcation of the Punmah Glacier, the name itself is expressive and is derived from "*Skeen*" an ibex, and "*Mang*," a level place in Balti = *Marg*, Kashmiri, *Maidan* Hindustani—which disposes of it as a likely designation for a peak.

Next we have "Chiring" given as the name of K2, the second highest peak in the Himalayas, quite as inaccurate, for it happens to be the name of another camping spot or bivouac at the end of a spur and about halfway between Skeenmang and the Mustakh pass, as used about the period I was there (1860). It is situated just above a very narrow part of the glacier, where its action is most marked on the rocky sides. "*Chirna*" in Hindustani is to rend, tear, and Chiring Gause is the name of all that portion extending six miles up to the main watershed.

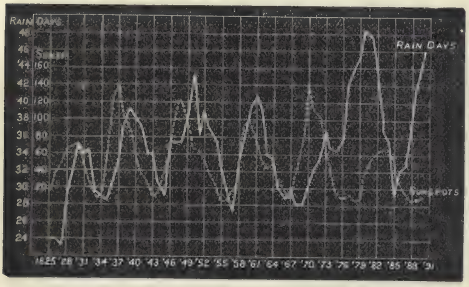
Shalford Park, Guildford, January 7.

The Weather of Summer.

THE number of days with rain, in summer, at Greenwich, during most of this century, has been subject to a pretty regular fluctuation. The curve (from 1825) having been smoothed by means of five-year averages, we obtain that shown in the diagram. And putting with it a curve of sun-spots, we find a strikingly definite correspondence (somewhat "lagging" in character) throughout at least four of the sun-spot cycles, the rain day maxima coming soon after the sun-spot maxima, and rain day minima soon after sun-spot minima. In recent years, however, the curves appear to have got out of step (so to speak) with each other; so that, *e.g.* we find a rain day *maximum* in 1880, two years after the sun-spot *minimum* of 1878, and a rain day *minimum* in 1885, two years after the sun-spot *maximum* of 1883.

I do not remember to have seen the facts of our summer weather put in this way. But it is well known that, in the discussions which arose some time ago about sun-spots and rainfall, there appeared some reason to believe that in the period of those four earlier sun-spot cycles, at least, we had had, on the whole, wetter years about sun-spot maxima than about the minima. A good deal was written on the subject (as your own columns show) in the seventies; and the data used seem to have been generally those of annual rainfall. Of late, apparently, the matter has attracted less notice; for the reason (I suppose) that the correspondence referred to has not been maintained, and recent facts have seemed rather against the theory of a causal relation between the two orders of phenomena.

Thus the teaching of the curve here given appears to harmonize, in general, with known facts about annual rainfall. I do not propose to try and weigh the data so far as they may be considered to favour the theory just indicated (earlier and greater part of the curve), nor the data which may be considered adverse (in the short, later part). It seems to me that the curve may be usefully studied *per se*, apart from any relation to sun-spots. Thus we might note the fact that all those maxima where our summers have got to a turning point from wet to dry have been quite near the beginnings of the decades. The dates are 1830, 1839, 1850, 1861, and 1880. The curve ends at 1890 (the final point representing, of course, 1888–92), and the position of this point, together with the date, seem to warrant our looking for an early descent of the curve, and a commencing series of (on the average) drier summers than we have had lately.



Smoothed curve of rain days in Summer at Greenwich, with curve of Sun-spots.

We might also note that the minima of the curve have ranged from the fives to the eights. Thus we have, 1827, 1835, 1845, 1857, 1868, 1885. Should the recurrence continue, we might look for the next minimum about 1895–1898. Of course there may be difference of opinion as to the strength of the presumption here afforded for such a forecast, and no good reason is offered (beyond experience) why the curve should now take the course roughly indicated.

It is not at variance with the above view that there is reason, it would appear, to anticipate soon a series of wetter *years*. In an article contributed to the *Times* of October 22 last year (cited in NATURE, vol. xliv. p. 630) Mr. Symons says: "There is no doubt that since 1887, at all events, the rainfall over England has been much below the average; and a consideration of all the facts leads to the conclusion that such a period of scarcity is very likely to be followed by one of abundance, and that the coming few years will probably be more rainy than those recently experienced, although possibly the increase will not occur in the summer months—at a time when it would be most noticed."

A. B. M.

"Aminol."

MY attention has only now been called to the letter of Dr. Klein, which appeared in NATURE, *ante*, p. 149.

To the remarks referring to "Aminol" (with Periodate I am in no way concerned) I desire, with your kind permission, to make the following reply, as they contain inaccuracies which, if not corrected, must do me injury.

The samples of "Aminol" alluded to by Dr. Klein were sent by me to a number of medical practitioners who had kindly consented to give it a trial. The strength of the samples was 1 in 5000.

Dr. Klein has carried out between September, 1890, and March, 1891, five separate consecutive series of experiments with "Aminol," with the object of testing its applicability to the treatment of certain external disease processes. His results are recorded in a report, the summary and conclusions of which were published last year with his full approval. The strength of solution employed in the first four series (which were only of a tentative nature with a view to arrive at a proper strength of solution for practical application) was 1 in 6000; in the fifth series a solution of the strength of 1 in 600 was used. Dr. Klein's letter leads one to suppose that he operated only with the latter strength.

The pathogenic germs selected for testing the power of the disinfectant were: spores of *Bacillus anthracis*, sporeless *Bacillus anthracis*, *Staphylococcus aureus*, *Bacillus diphtheriæ*, and *Streptococcus erysipelatis*. Amongst the results obtained with the solution of the strength of 1 in 6000 his report mentions the following: In Series IV., "On *Staphylococcus aureus*, which may be taken as the most resistant microbe amongst those associated with surgical and other external disease processes, the "Aminol" solution (1 in 6000) did produce an effect, though a limited one, after two hours already, and after twenty-four hours destroyed the microbes." In Series I.: "'Aminol' solution (1 in 6000) kills the *Bacillus diphtheriæ* in two hours. This was confirmed in Series III." In this connection it deserves to be noted that I possess already ample evidence, which will be published in due course, of conspicuous successes obtained in practice not only with the solution of the strength of 1 in 5000, but also with dilutions of the same, even to 1 in 20,000.

Dr. Klein's statement of the results which he obtained with "Aminol" in the strength of 1 in 600 is misleading. He says: "Spores of *Anthrax bacilli* remained unaffected after eight hours, only after an exposure of twenty-four hours did the number of living spores decrease; but some escaped disinfection even after so long an exposure. Now what are the facts? I quote from Dr. Klein's report:—

"Spores of *Bacillus anthracis* after 1, 2, 8, and 12 hours	good growth.
"Spores of *Bacillus anthracis* after 24 hours	growth reduced from 100 to 6."

Is it putting the case fairly or even clearly, seeing that no tests were made between twelve and twenty-four hours, to say "only after twenty-four hours did the number decrease," and seeing that only 6 per cent. remained after twenty-four hours? Is not that a decrease practically amounting to disinfection? Would it be extravagant to assume that the insignificant percentage remaining would be eliminated after a very little longer exposure (say another hour), and is there any doubt that a solution of the strength of 1 in 500 or 1 in 400 would have accomplished complete disinfection in a much shorter time than twenty-four hours? But in order to illustrate the significance of the results actually obtained with this solution of the strength of 1 in 600, let us see which other disinfectants can kill anthrax spores in twenty-four hours. I quote from "Koch on Disinfection," abstracted and translated by Whitelegge, published by the New Sydenham Society:—

(1) "For practical purposes a disinfectant should not require much longer than twenty-four hours."

(2) "Except chlorine, bromine, and iodine, only mercuric chloride, osmic acid, and potassic permanganate (5 per cent.) destroyed anthrax spores within twenty-four hours. Since a 5 per cent. solution of permanganate is inadmissible for disinfection in bulk, and osmic acid is out of the question, we have left only mercuric chloride and iodine, bromine, and chlorine."

The strengths in which the above-named substances succeeded in destroying anthrax spores in twenty-four hours are stated in Koch's tables thus:—

Permanganate,	aqueous solution	5 per cent	(1 in 20).
Bromine	,,	2 ,,	(1 in 50).
Chlorine	,,	?	
Iodine	,,	?	
Mercuric chloride	,,	1 per cent	(1 in 100).
Osmic acid	,,	1 ,,	(1 in 100).

Now put against this the fact, quoted above, that Dr. Klein found "that 'Aminol,' strength 1 in 600, killed 94 per cent. of anthrax spores in twenty-four hours," and further (I am quoting his report again), "that this solution is a perfectly harmless fluid as regards the human organism; therefore no undesirable disturbances could ensue owing to its being absorbed; this is well known to be the fact with some antiseptics, as in carbolic acid applications or in the use of perchloride of mercury."

Does not all this clearly establish the claim of "Aminol" to be called not only a true disinfectant, but a most potent and a most safe one at the same time?

But with all this (I mean what relates to its effect on anthrax spores) its application in medical and surgical practice has nothing to do, unless it be to demonstrate its comparative potency, for, as Dr. Klein himself points out in his report, "The spores of *Bacillus anthracis* may be left out of consideration, as they do not occur in the living body; under these conditions the *Bacillus anthracis* is always sporeless; a malignant carbuncle of the skin contains the *Bacillus anthracis* only in the sporeless state, and in infection with anthrax generally the bacilli are always in the sporefree state both in the blood and in the tissues."

What is of real importance in practice is the effect of "Aminol" on the other pathogenic germs on which Dr. Klein has tested it. And here again his letter states the case in a manner which is apt to mislead: "*Anthrax bacilli*, *Staphylococcus aureus* and others were destroyed, but only after a lengthy exposure."

Now what does his report say? "Series V. From this series it will be seen, therefore, that the solution used in the same (1 in 600) acted very differently from that used in the previous experiments (1 in 6000) inasmuch as the *Staphylococcus aureus*, which was not killed heretofore in eight hours, was in this instance completely disinfected in that time, and was considerably reduced even in one hour. The sporeless *Bacillus anthracis*, *Bacillus diphtheriæ*, and *Streptococcus erysipelatis* were killed in one hour." Can it be fairly said, then, that these were killed only after lengthy exposure, and does the word "only" apply at all to the one-hour results, when it is considered that there was no test made under the one hour? What is there to show that those of which there was no growth after one hour's exposure to the disinfectant had not been killed after ten minutes already?

Does it not look, then, as if Dr. Klein had penned his letter without consulting either his notes or his report?

A word in conclusion. Dr. Klein, for whom perhaps nobody entertains a higher personal regard than myself, may rest assured that the designation, "a true disinfectant," is meant by me to apply only to such strengths of solutions of "Aminol" as can compete with those substances and their respective strengths to which Koch has accorded that appellation. Nor need he to apprehend that anything has been or will ever be done by me intentionally committing him to what is not fully warranted by his actual results as recorded in his authorized published report. HUGO WOLLHEIM.

101, Leadenhall Street, E.C., January 2.

THE point at issue between Mr. Wollheim and myself is a very simple one, and needs no long explanation on behalf of Mr. Wollheim. As you will see from the letter which you kindly printed in NATURE, *ante*, p. 149, Mr. Wollheim, without my authority, has sent round a leaflet with my name on it, accompanying bottles of "Aminol," stated to be "a true disinfectant."

1. On this leaflet my name is introduced in a somewhat misleading manner, for it quotes to a large extent from my reports on the lime and brine experiments on microbes without saying so, but leaving the reader to infer that these reports of mine refer to "Aminol."

2. Mr. Wollheim never asked my permission or informed me of his intention of sending with each sample bottle of "Aminol" such a leaflet. It is unnecessary to say that had he asked me whether he could use my name on a wrapper of a patent medicine I should have emphatically answered *no*. He has recently informed me that he has cancelled the leaflet.

3. The samples of "Aminol" sent out were of the strength of 1 in 5000, the experiments in which I showed that "Aminol" possesses a certain disinfecting power were made with a strength of 1 in 600. This strength did not kill spores of anthrax in 12 hours; 1 in 6000 did not kill *Staphylococcus aureus* in 8 hours.

A substance which, like the "Aminol" sent out (viz. 1 in 5000), cannot kill *Staphylococcus aureus* in 8 hours, and has practically no effect on spores of *Bacillus anthracis* cannot be considered "a true disinfectant."

To show that Mr. Wollheim had a very strange idea about the whole matter, one has only to compare the actual facts of the case, as regards "Aminol" of the strength of 1 in 5000, with the motto put on the leaflet and the inscription on the label of the samples. For Mr. Wollheim quotes Koch to the effect that no disinfectant can be called a true disinfectant that does not kill spores, and notwithstanding that I have shown that "Aminol" even of the strength of 1 in 600 cannot kill spores in 12 hours, yet Mr. Wollheim advertises the "Aminol" of the strength of 1 in 5000 as "a true disinfectant." A true disinfectant kills spores after short exposure; a substance that requires many hours to do so cannot claim the name of a specific disinfectant. Vinegar, dilute acids, alkalies, and a host of substances affect spores after exposure for many hours (8, 12, and 24 hours), yet no one would consider these substances as specific disinfectants.

Again, a substance used in a certain strength (say 1 in 600) may have considerable disinfecting power on non-spore bearing microbes, with or without having any conspicuous action on spores. The same substance more diluted (say 1 in 5000) may have retained such action only to a very insignificant degree. Take for instance perchloride of mercury; while this substance is a powerful disinfectant when used in the strength of 1 in 500, 1 in 1000, even 1 in 2000, it has greatly less effect when used in more increased dilution.

No one is justified in advertising perchloride of mercury of the strength of 1 in 100,000 as "a true disinfectant," knowing that 1 in 500 or 1 in 1000 only can be so called. How much more does this hold good for a substance like "Aminol," which even in the strength of 1 in 600 does not kill the spores of anthrax in 12 hours, a period which for practical purposes of disinfection is out of the question. E. KLEIN.

19, Earl's Court Square, S.W., January 9.

Super-abundant Rain.

IN NATURE of November 10 the fact that "very nearly one-third" of the annual rainfall fell in one month at Nant-y-Glyn, in North Wales, is recorded as "remarkable."

But at Peshawar, on the north-west frontier of India, we received during last August a rainfall of 17·75 inches, the average local annual fall, calculated from the last fifteen years, being 13·51 inches.

We therefore had very nearly sixteen months fall in one month, and by far the largest portion of this fell in ten days of the month.

I need hardly add that the whole valley was flooded, and that we have since paid for our super-abundant rain in the form of very prevalent and fatal malarious fever. H. COLLETT.

Peshawar, December 19, 1892.

Earthquake Shocks.

THERE were two unmistakable shocks of earthquake on the afternoon of Tuesday, January 3, the first at 2h. 15m. 15s. G.M.T., and the second at 2h. 17m. I was sitting in a railway carriage at Severn Junction Station waiting for the Bristol passengers, when I felt a sensible upward movement of the seat (as if pushed from below) and saw the carriage sway. The movement was from south to north (*i.e.* at right angles to the railway). This was repeated four times in about six seconds. At 2h. 17m. there were two more (less strong) shocks. The carriage was placed in a siding, and there was no train at the station, and the air was calm and frosty. Ice was said to have cracked near here at this time. E. J. LOWE.

Shirenewton Hall, Chepstow.

A Brilliant Meteor.

ON Wednesday, January 7, at about 6.35 p.m., I was fortunate enough to see a brilliant meteor descending a little north of Castor. My attention was drawn to it by the brilliant light it threw over the country. The head was a ball of dazzling white and the tail yellow, with red streaks. It disappeared before reaching the earth, and I heard no report or rushing sound whatever.

As the duration was only a few seconds the above are more impressions than observations. W. POLLARD.

Pirton, Herts, January 7.

CHEMICAL SOCIETY'S MEMORIAL LECTURES.

AT an extra meeting of the Chemical Society, held on December 13 last, this being the first anniversary of the death of Stas, a paper was read and discussed which had been prepared for the occasion by Prof. J. W. Mallet, F.R.S., of the University of Virginia, U.S.N.A.—himself a high authority on atomic weight determinations, and well known to chemists through his papers on the atomic weights of aluminium and gold, published by the Royal Society of London.

The lecture marks a new departure in the work of the society. Hitherto our learned societies have been in the habit of publishing more or less complete—it would probably be nearer the truth to say incomplete—obituary notices of their foreign members. The Chemical Society has come to the conclusion, however, that inasmuch as its foreign members are always men of great distinction who, as a rule, have lived a considerable number of years after accomplishing their life work, it will be to the advantage of its fellows and of chemists generally, if the obituary notices of foreign members take the form of critical monographs of the subjects with which they have principally dealt.

The anniversary of the death of the foreign member is obviously the most appropriate occasion for the delivery of such a lecture. During the past year the society has lost two of its foreign members: Hermann Kopp, noted as an historian, as well as on account of his very numerous exact determinations of atomic volumes and specific heats, and A. W. von Hofmann. The life and work of the first mentioned will form the subject of a lecture to be delivered on February 20 next, by Prof. Thorpe, the Treasurer of the Society, than whom no one is more qualified to undertake the task. Prof. Thorpe is not only a pupil of the deceased chemist, but has reverently followed in his footsteps—having very largely extended Kopp's observations on atomic volumes in an elaborate investigation, the importance of which was recognised by the Chemical Society in 1881 through the award to him of its first Longstaff medal.

Von Hofmann, although originally a foreign member, became an ordinary member of the Chemical Society on coming to England as professor at the school in Oxford Street, long since merged in what is now known as the Royal College of Science, London. Hofmann was never again regarded as a foreigner; he served the society both as foreign secretary and as president, filling one of the vice-chairs during the remainder of his life. It is felt that owing to the special nature of his relations to the society and to english chemistry, it will be necessary to deal with his case in an exceptional manner; it is therefore hoped that in May next Lord Playfair—who was so intimately connected in his early days with chemical science and with the society—in the first place will picture the state of affairs chemical at and prior to the time of Hofmann's arrival in England. Sir F. Abel, Hofmann's first pupil and assistant, will follow with an account of Hofmann at the Royal College of Chemistry, calling to his aid for this purpose the remaining friends and pupils of Hofmann. The coal-tar colour industry, which has now attained such important dimensions, it is well known, had its origin in the Oxford Street laboratory, and Dr. Perkin—its parent—has consented to sketch the history of its development. In this manner it is hoped to impart considerable "local colour" to the Hofmann memorial lecture, thereby distinguishing it from the notice which is being prepared by the German biographers.

Passing now to Prof. Mallet's lecture on Stas, which is of considerable length, as it will occupy fully sixty pages in the Society's Journal. The biographical portion is brief, as a number of such sketches have already been published. Stas was born at Louvain on August 21, 1813. He graduated as Doctor of Medicine. His taste for chemical research was evidenced in 1835, when, together with a friend, he investigated in an attic of his father's house the crystalline substance phloridzin which they had extracted from the root bark of the apple tree. He continued the study of this substance in Dumas' laboratory in Paris, and it is an interesting proof of the acumen of Berzelius that in his annual report on the progress of chemistry he referred to this first research made by Stas with praise, and a prediction of future eminence for the author.

The starting-point of the long train of research with which his name will ever be associated was the redetermination of the atomic mass of carbon which Dumas and he together undertook, in order to explain the fact, noticed by Liebig and others, that the sum of the carbon and hydrogen found in hydrocarbons by the combustion process, as calculated from the carbon dioxide and water, not unfrequently exceeded the quantity of material analyzed. As the result of this investigation, which was carried out with unprecedented care and the most elaborate precautions, the value hitherto accepted for carbon on the authority of Berzelius ($76·432$ $O = 100$) was considerably reduced (to $75·005$). In 1840 Stas was appointed Professor in the École Royale Militaire at Brussels; he held this post for more than a quarter of a century, until an affection of the bronchial tubes and larynx obliged him to give up lecturing. He then received an appointment in the Mint, but resigned this in 1872 on political grounds, and withdrew into private life. He appears to have been a man of great independence of character.

Apart from his atomic weight investigations Stas did much work of value in other departments. His method of separating alkaloids from organic messes—no other name is applicable—which has been of such service in subsequent toxicological inquiries, was devised in 1850, in the course of the inquiry into the celebrated Bocarmé nicotine poisoning case. He examined into the methods of hydrolysing fats for the purpose of a report on the chemical section of the London 1862 Exhibition. In connection with the preparation of international standards he took an active part, along with Devile, in the inquiry into the properties of the platinum metals. It is known also that he did important work for his Government in investigating alloys for use in the construction of artillery.

Prof. Mallet prefaces his account of Stas's special investigations by an historical survey of the fundamental ideas which have gradually led up to the question, What is the mass of an atom of a particular element? Even in and beyond the days of Cavendish and Priestley the fact that atmospheric air was found of constant or nearly constant composition was long a stumbling-block in the way of clear distinction between a homogeneous compound and a uniform mixture. To the labours of Van Helmont, Boyle, and Boerhave much credit is due for the gradual advance towards the doctrine of the conservation of matter. The discoveries of Black and Cavendish brought it further into view, and it assumed its due importance and began to receive universal recognition with the constant appeal to the balance which Lavoisier made and taught others to make. Next came a comparison of the quantities of different substances, at first chiefly the then known acids and bases, which would enter into combination with each other. Proust, in the course of his controversy with Berthollet as to the fixedness of combining proportions, had observed that in certain cases it was true that in different compounds, consisting of the same constituents, for a fixed quantity of one constituent, the different quantities of another constituent bear to each other a simple multiple or sub-multiple relation. To Dalton, however, belongs the honour of announcing the principle as a general one, and of basing upon it a true chemical atomic theory of the nature of matter. Berzelius, in the early years of the present century, with apparatus in many respects inferior to that of the present day, and with scarcely any aid from chemical manufacturers in preparing pure materials and reagents, but with unsurpassed manipulative skill and the most honest criticism of his own work, produced the first fairly trustworthy list of numbers representing the proportions by weight in which the elements combine. Berzelius began work in this direction in 1807, his attention having been attracted by Richter's investigations; but soon afterwards he became acquainted with Dalton's new atomic theory of the nature of combination, and appears to have been impressed with its great importance, and at the same time with the need of more exact experimental data for its support and development. The wonderful accuracy of Berzelius's work generally is illustrated, as Prof. Mallet points out, by the fact that his number for oxygen, 16·021, becomes 15·894, almost exactly agreeing with the latest determinations of the present day, if the weighings of Dulong and Berzelius's three experiments on the synthesis of water be corrected for the buoyancy of the air. Since Berzelius many other chemists have worked in the same field, but his most worthy successor in such labours has undoubtedly been Stas. With greatly better resources in the way both of apparatus and material, with equal earnestness in seeking for the truth, with equal intelligence and skill he took up the task which became that of the largest part of his scientific life, and for a more limited list of elements than Berzelius had investigated, produced results of a degree of accuracy which it is high praise to say would have delighted no one more than Berzelius himself. He aimed at the determination with greater precision than any one before him had attained of the atomic weights of some ten or twelve of the elements. But by so determining these constants he endeavoured also to settle several general questions of fundamental importance in regard to matter as studied by the chemist.

Thus it has generally been assumed as true beyond dispute since the early part of the present century, that the mass of an atom of a given element is a constant quantity. This has, however, occasionally been doubted, and Stas himself considered the question as one requiring examination. His researches, however, lend no support to it. On this point Prof. Mallet expresses himself strongly in favour of the orthodox view.

Assuming that the atomic weights are immutable values, the question arises, Are they commensurable? This is the much-discussed hypothesis of Prout, the origin and development of which is very fully discussed by Prof. Mallet. A widespread feeling at one time undoubtedly existed among chemists that Prout's hypothesis, that the atomic weights of the other elements are integer multiples of that of hydrogen, if not true in its original form would ultimately prove to be so at least in a modified form. That Stas began his work under the influence of this feeling is clear from his own words:—

"Je le dis hautement lorsque j'ai entrepris mes recherches, j'avais une confiance presque absolue dans l'exactitude du principe de Prout."

But his experimental results clearly contradicted the hypothesis, and he satisfied himself that the atomic weights of the elements which he determined with such precision could not with truth be represented by integer multiples of the atomic weight of hydrogen, or the half or the fourth of this unit. In his own words:—

"Aussi longtemps que, pour l'établissement des lois qui régissent la matière on veut s'en tenir l'expérience, on doit considérer la loi de Prout comme une pure illusion. La simplicité de rapport de poids que présuppose l'hypothèse de Prout entre les masses qui interviennent dans l'action chimique, ne s'observe donc point dans l'expérience; elle n'existe point dans la réalité des choses."

The great majority of chemists—Prof. Mallet remarks—at the present day, are probably agreed in believing that the hypothesis of Prout has been shown by Stas to be untenable. But the fact that so many well determined atomic weights, referred to hydrogen as unity present numbers *nearly approaching integers*, is very striking and calls for further investigation. Stas himself is quoted as admitting this much. Prof. Dewar, in the course of the discussion after the paper was read, drew special attention to this question and gave several most striking instances of the nearer approach to whole numbers which resulted from a recalculation of the accepted values, using the lower value for oxygen (15·87) which so many recent researches tend to support, although on the other hand, of course, some of the values now near to whole numbers are considerably thrown out. Evidently there is ample opportunity for further experimental investigation of this all-important problem, and it is impossible—notwithstanding the extraordinary degree of accuracy attained by Stas—to formulate any final conclusion. The supreme interest attaching to the problem was clearly recognised by Stas himself, as the following words show:—

"Au point de vue de la philosophie naturelle, la portée de l'idée de Prout est immense. Les éléments des corps composés que nous considérons comme des corps simples en égard à leur immutabilité absolue pour nous, ne seraient eux-mêmes que des corps composés. Ces éléments, dont la découverte fait la gloire de Lavoisier et a immortalisé son nom peuvent être considérés ainsi comme dérivant de la condensation d'une matière unique: nous sommes naturellement conduits à l'unité de la matière, quoi qu'en realité nous constations sa pluralité, sa multiplicité."

This quotation is almost alone sufficient to show that Stas was a philosophical chemist of the highest order, and not a mere mechanical worker, as has sometimes been supposed; his unwearied attention to minutest details has undoubtedly served to completely overshadow the philosophical motives and aspirations by which he was guided.

Stas also endeavoured to obtain evidence with regard to the possible dissociation of the elements at high temperatures and to this end purified his materials with every imaginable precaution. The skill with which he carried out his operations is attested by the statement made by Mr. Crookes, the chairman at the reading of Prof. Mallet's paper, that he had seen in Stas's laboratory a large mass of potassium chloride, which Stas had been years in preparing, and in which he had failed to find a trace of sodium even spectroscopically—such an achievement appears almost inconceivable to the chemist. Stas, in fact, in the course of his work investigated the methods of analysis to be used with a degree of rigour, and discovered and applied refinements upon older methods of experiment with a degree of patience and skill, such as had never before been used in chemical investigation. Only those who are thoroughly conversant with such work can fully appreciate his labours; they probably will agree that owing to the multitude and diversity of the precautions to be taken, his work is the most difficult hitherto attempted, and that he stands unsurpassed among all who have undertaken the execution of exact physical measurements.

A lengthy section of Prof. Mallet's paper is devoted to the consideration of the objects to be aimed at and the methods to be pursued in future work. He advocates the repetition by competent hands of some one at least of Stas's fundamental results, calling attention to Stas's own emphatic expression of the wish that this should be done. It is also most important that no distinction should be made between rare and common elements, and that the atomic weights of all should be determined with the least possible delay and the highest attainable degree of accuracy. Certain of the elements particularly call for a more searching and exact investigation of their atomic masses, *e.g.* elements such as tellurium, which occupies a position in the periodic system not in harmony with its atomic mass, and cobalt, which plainly occupies the intermediate position between iron and nickel, and therefore should be intermediate in atomic mass.

In a number of cases the accepted value is based on the investigation of but a single interchange, the value for iron, for instance, being practically based on the results obtained on converting the metal into ferric oxide, and *vice-versâ;* and the relation of hydrogen to oxygen having been established by the reduction of cupric oxide. It is desirable that in such cases other and independent methods should be resorted to, *e.g.* that oxides of a number of metals other than copper should be reduced, with the object of detecting possible constant errors.

It is eminently desirable that an attempt be made to directly determine the ratio of hydrogen to each of the halogens without in any way bringing in the atomic mass of oxygen. Prof. Mallet suggests various methods deserving of study. Also it is very important that the metals of the yttrium and didymium groups should be further investigated. Prof. Mallet rightly terms the yttrium group the opprobrium of inorganic chemistry.

Nearly all that has been written hitherto in regard to the periodic relationship among the elements has involved the use of roughly approximate values only; but it is time that the foundation be laid for a more minute and critical study of the periodic system of classification. Anomalies in the classification as we now find it in our books, glimpses of more detailed relations than as yet clearly appear, tantalizing suggestiveness in so much of what is already before us, call for more precise determinations of the numbers we would discuss before we allow premature discussion to drift into mere fanciful speculation.

In regard to the methods which it is desirable shall be pursued in the determination of atomic masses, Prof. Mallet has much to say. He discusses the selection of processes, the purity of materials, the very numerous directions in which vigilance must be exercised in order to avoid extraneous or accidental causes of error, the quantities of material to be used, the practical precautions to be observed so as to secure accuracy of manipulation and in weighing and measuring, the mode of stating and calculating results, finally calling attention to the advantage to be derived from the application of greater working force and ampler means than can be commanded by private individuals to the determination of atomic masses; with reference to this last point, during the discussion on the paper, the opinion was freely expressed that it was undesirable that such work should be carried out in organized public or semi-public laboratories. The question is, no doubt, a difficult one to settle—such work demands a special temperament combined with genius of a high order and an infinite capacity for taking pains, qualities which must rarely occur united in a single individual. Moreover, in order that the value of a result may be appraised, it is essential to overlook every detail involved in the determination. Given the man, however, there can be no longer a doubt that every possible assistance he may require should be afforded him. It is marvellous that men like Berzelius and Stas, working all but alone and unaided, should have achieved results of such magnitude and universal importance—the moral effect of their example is certainly not less important than are the actual results of their labour.

The last section of Prof. Mallet's paper is devoted to the discussion of the form in which it is desirable finally to state the results. He here advocates the uniform substitution of the expression "atomic mass" for "atomic weight," on the ground that precision in language conduces to precision in thought—an aphorism far too commonly disregarded by chemists. We have now clear conceptions of atoms having constant mass for the same element, of determinable difference of mass in the case of different elements, the several masses and numbers of which regulate the composition of all known substances and the products resulting from interaction among them. The atomic theory has advanced far beyond the condition of a mere working hypothesis on which chemists long stood with more or less uncertain feet; but even if this were not so, considering it, to use a common metaphor, only as a scaffold, there is no good reason, so long as we stand on it and work from it, that we should be careless about tying our scaffold-poles and nailing our planks.

Lastly, Prof. Mallet urges that all atomic masses shall be expressed in terms of the mass of the hydrogen atom taken as unity, objecting strongly to the change to $O = 16$ which several writers have recently advocated, the most objectionable argument put forward in favour of such change being, he thinks, that the numbers we use are expressive of *ratios* only—that any figures are allowable which correctly express combining ratios, and that there are no reasons for using one set of figures rather than another save mere arithmetical convenience. This involves a grave error, as in adopting as unity the mass of a single atom of any particular element, preferably that one of which the mass is the smallest, we have reason to believe that we express the mass of all the others in terms of this as a really existent, definite, and constant quantity of matter. It is, indeed, difficult to understand when the scientific necessity in so many cases of taking hydrogen as the unit is realized, how the change to $O = 16$ can be advocated except on the simple utilitarian plea that it is to the analyst's convenience.

Prof. Mallet's monograph is undoubtedly a most admirable exposition of the philosophical lessons to be learnt from the contemplation of Stas's labours.

EXTINCT MONSTERS.[1]

THE volume with this title treats of large animals. It is clearly and simply written, without any pretence at being scientific, and is an excellent book for boys and unlearned people who are curious to be informed upon the subject of fossil animals. It would have escaped criticism altogether but for emphatic words of praise in the preface, and one or two passages in which the author, with second-hand information, speaks authoritatively of predecessors who restored extinct types of life with the slender materials which were available forty years ago. The attraction of the volume and its novelty is a series of restorations of saurians and mammals drawn chiefly by Mr. Smit. These for the most part are based upon the restorations of skeletons made by Prof. Marsh, whose discoveries have inspired Mr. Smit's pencil as much as they have influenced the author's pen. There is not much anatomy beneath the skins of the "Monsters," and they have an aspect as though cotton-wool had taken the place of muscle, or as though the drawings were models for the "Lowther Arcade." This, however, is of less importance than the answer given to the question, Are they reasonably faithful to nature? It does not seem to me that they can claim this merit; they are only reasonably faithful to Marsh. Prof. Marsh draws an animal so as to give one type the maximum height to which the bones can be hoisted; while another is given the maximum length to which the remains can be extended. My own studies would not have led me to reconstruct one of the extinct reptiles upon the lines which are adopted in these restorations. As an example of how a restoration should not be made, we may instance the figure of *Stegosaurus ungulatus* (p. 104), in which the management of the limbs is out of harmony with the evidences of the muscular structure of the tail, and the supra-vertebral crest. The restoration of the Scelidosaurus from the Lias of England is unsatisfactory. There is no better ground for giving a kangaroo-like position to that animal than there would be for drawing Teleosaurus in the same position. The mobility of the neck as drawn is astonishing.

---

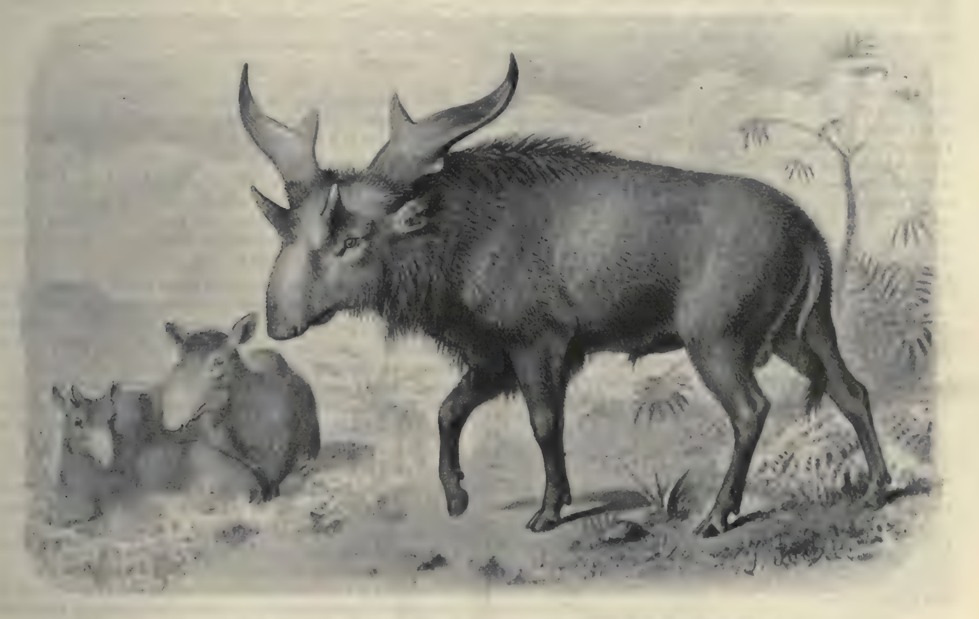
[1] "Extinct Monsters." A popular account of some of the larger forms of ancient animal life. By Rev. H. N. Hutchinson, B.A., F.G.S., with illustrations by J. Smit and others. (London: Chapman and Hall, Ld., 1892.)

The restorations of mammals are happier. The subjects diverge less from existing types. And probably the most successful in the volume is the spirited restoration of *Sivatherium giganteum* from the Sivalic Hills, though the Glyptodon and Irish Deer are meritorious.

In the text the author is generally content with telling the story of the history of science; but he sometimes strays into less safe matter. Thus an account is given of the eye of the Ichthyosaurus. And it is urged that the bony plates exercised a pressure on the eyeball, so as to make the eye more convex, and improve the definition of near objects. The study of sclerotic defences does not support this interpretation; and in at least one generic division of the Ichthyosauria the sclerotic plates do not overlap at all, but join each other by their lateral sutural margins.

It is perhaps unfortunate that the author gives currency to nomenclature and classification of the terrestrial types of saurians which may not always prevail. If the genera with a bird-like type of pelvis are terrestrial representatives of birds, and the genera with a reptilian type of pelvis are terrestrial wingless representatives of Pterodactyls, then it may not be an advantage to have the Dinosaurs treated as a homogeneous group, or the divisions adopted by Prof. Marsh, or in the British Museum (Natural History), handed on to the unlearned as representing the best available classification. On page 75, the author introduces a restored skeleton of Megalosaurus, which is attributed to Prof. Marsh. The skeleton certainly is not referable to Megalosaurus, which never has the pubic bones or the ilium constructed as in the figure. The restoration has been previously used in Nicholson and Lydekker's "Palæontology," and in Dr. Woodward's "Handbook to the Geological Department of the British Museum," but we do not remember any published authorization for the use of Prof. Marsh's name as authority for confounding Megalosaurus with the allied American type.

Another example of the same kind of interpretation occurs in dealing with Stegosaurus. It is said to have been proved that bones to which the name Omosaurus has been applied really belong to Stegosaurus, and that an unnecessary name has been disposed of. The ground on which this determination is made, not being stated need not concern us now; but it is undesirable that a popular work, whose main merit is that it does not pretend to teach the facts of science, should appear to enunciate judgments on scientific problems. Having described the immense enlargement of the spinal cord in the sacral region of Stegosaurus, the author remarks:—"So this anomalous monster had two sets of brains—one in its skull, and the other in the region of its haunches!—and the latter in directing the movements of the huge hind limbs and tail did a large part of the work." Remarks of this character are sure to be misunderstood, are out of place and incorrect.



The four-horned extinct Mammal *Sivatherium giganteum*. The animal on the left is Heladotherium.

The author has read much, and shown an excellent capacity for quotation, but has not always succeeded in using the newest results. He has conscientiously endeavoured to tell the story which is contained in his quotations, but beyond this he does not pretend, except in the occasional use of supposed scientific principles as a means of accounting for facts of animal structure. He has dealt with a subject of great difficulty with commendable clearness, and will interest readers who would be unable to follow a more technical exposition of extinct types of life. H. G. S.

ENERGY AND VISION.

THE interesting researches of Prof. S. P. Langley on energy and vision have recently been published in the Memoirs of the American National Academy of Sciences. From this we gather that he was led to investigate the question by the fact that it was not generally recognized how totally different effects may be produced by the same amount of energy in different parts of the spectrum. Two series of experiments were necessary, the first to determine the amount of energy in each ray, the second to observe the corresponding visual effect. The energy was determined as heat by the use of the bolometer, the heat dispersed by a prism being very nearly proportionate to the energy.

In the second series of experiments a beam of sunlight from a siderostat passes through a small hole in a darkened room and falls on a slit with a standard width of 0·1 mm. It is then received on a collimating lens of 11·9 centimetres aperture and 755 centimetres focal length, after which it passes through a prism of about 60° refracting angle. The spectrum thus formed is reflected and brought to a focus on a second slit of one millimetre aperture by a concave mirror, any particular colour being adjusted on the slit by a rotation of the prism. This second slit is screened from all possible stray light by a dark curtain, and is used as a source of illumination for a series of numbers from a table of logarithms, which is attached to a sliding screen. The greatest distance from the slit at which the figures could be distinctly read was then determined, and the law of inverse squares applied. For the brighter colours of the spectrum, the light entering the first slit was reduced by an adjustable photometer wheel.

Actinometric measures were made during the progress of the photometric observations, and showed a solar radiation of 1·5 calories per square centimetre per minute; this naturally being an essential unit.

The energy necessary to give the bare impression of luminosity in different parts of the spectrum, expressed in terms of horse-power, was found to be roughly as follows, the *minimum visibile* being defined as the feeblest light which is observed to vanish and reappear when silently occulted and restored without the knowledge of the observer:—

		Horse-power.
Violet (λ 400)	...	0·000000 000000 00018000
Green (λ 550)	...	0·000000 000000 00000075
Scarlet (λ 650)	...	0·000000 000000 00017000
Crimson (λ 750)	...	0·000000 000000 34000000

These values were derived from observations made by a single observer, Mr. F. W. Very, and are, of course, subject to a large percentage of error.

The general results of the investigation may be best summarized in Prof. Langley's own words:—

"The time required for the distinct perception of an excessively faint light is about one-half second. A relatively very long time is, however, needed for the recovery of sensitiveness after exposure to a bright light, and the time demanded for this restoration of complete visual power appears to be greatest when the light to be perceived is of a violet colour. The amount of energy required to make us *see* varies enormously according to the colour of the light in question. It varies considerably between eyes which may ordinarily be called normal ones, but an average from those of four persons gives the following proportionate result for seven points in the normal spectrum, whose wave-lengths correspond approximately with those of the ordinary colour divisions, where unity is the amount of energy required to make us see light in the extreme red of the spectrum near A, and where the six preceding wave-lengths given correspond approximately to the six colours, violet, blue, green, yellow, orange, red.

Colour	Violet	Blue	Green	Yellow	Orange	Red	Crimson
Wave length	400	470	530	580	600	650	750
Luminosity	1600	62,000	100,000	28,000	14 000	1200	1

It appears from this that the same amount of energy may produce at least 100,000 times the visual effect in one colour of the spectrum that it does in another.

If now it be inquired what the actual value of unity is in ordinary measure, we are able to give this also with a fair approximation, and to say that the *vis-viva* of the waves whose length is 7500 (tenth metres) being arrested by the ordinary retina, represents work done in giving rise to the sensation of the deepest red light of about 0·001 of an erg in one-half second.

NOTES.

THE Prince of Wales has consented to become Chairman of the Committee for the memorial of the late Sir Richard Owen, and to preside at a meeting to further the object, which will be held in the rooms of the Royal Society, Burlington House, on Saturday, the 21st inst., at half-past eleven o'clock. Admission will be by tickets, which may be obtained from Mr. Percy Sladen, Linnean Society, Burlington House, W. (who is acting as secretary to the Committee), or from Mr. H. Rix, assistant secretary of the Royal Society.

THE annual general meeting of the Royal Meteorological Society will be held at 25, Gre at George-street, Westminster, on Wednesday, the 18th instant, at 7.15 p.m., when the Report of the Council will be read, the election of officers and council for the ensuing year will take place, and the President (Dr. C. Theodore Williams) will deliver an address on "The High Altitudes of Colorado and their Climates," which will be illustrated by a number of lantern slides. This meeting will be preceded by an ordinary meeting, which will begin at 7 p.m.

THE general meeting of the Association for the Improvement of Geometrical Teaching is to be held at University College, Gower Street, W.C., on Saturday, January 14, the Rev. C. Taylor in the chair. At the morning sitting (11 a.m.) the report of the Council will be read, the new officers will be elected, and several candidates will be proposed for election as members of the Association. After the conclusion of the formal business Mis. Bryant will give "A Model Lesson on Geometry, as a Basis for Discussion." After an adjournment for luncheon at 1 p.m. members will re-assemble (2 p.m.) to hear papers by Mr. G. Heppel on "The Use of History in Teaching Mathematics," and Mr. F. E. Marshall on "The Teaching of Elementary Arithmetic." Members who wish to have any special matter brought forward at the general meeting, but who are unable to attend, are requested to communicate with one of the Honorary Secretaries. All interested in the objects of the Association are invited to attend.

DR. LUDWIG BECKER has been appointed to the chair of astronomy at the University of Glasgow.

THE Comet Medal of the Astronomical Society of the Pacific Coast has been awarded to Mr. Edwin Holmes, of London, for his discovery of a new comet on November 6.

ON Tuesday next (January 17) Prof. Victor Horsley, F.R.S., will begin a course of ten lectures, at the Royal Institution, on "The Functions of the Cerebellum and the Elementary Principles of Psycho-Physiology." The Friday evening meeting will begin on January 20, when Prof. Dewar, F.R.S., will give a discourse on "Liquid Atmospheric Air."

The severe frost which set in just before Christmas was succeeded by a rapid rise of temperature in Scotland on Friday, but in England the thermometer did not rise much above the freezing point until about twenty-four hours later. On the 5th and 6th instant the thermometer fell below 10° in many parts of Great Britain, and snow was falling in Scotland, which afterwards spread to many parts of England. The absolute shade minima recorded were −2° at Braemar, and 2° at Fort Augustus, in the north of Scotland. The distribution of pressure was unusually high over Scandinavia and northern Europe (inadvertently referred to in our issue last week as over these islands) having reached about 31·3 inches in Central Russia on the 4th, while areas of low pressure lay over the Gulf of Genoa and the south-west of Ireland. The latter depression gradually extended eastwards, causing strong easterly gales on the Irish coasts, while the anticyclone over Europe gradually gave way, the barometer at Haparanda on Monday being 1·5 inch lower than a few days previously. By Sunday all stations reported temperatures above the freezing point, while in the south-west of Ireland the maxima reached 47° and in the south of France even 63°. These changes were accompanied by rain in most parts of the country, which added materially to the rapidity of the thaw. Bright aurora was seen on Monday night in Scotland and Ireland. On Tuesday an anticyclone from the north-westward was spreading over our islands, with finer weather and lower temperatures generally, frost occurring in the north of Scotland and the central parts of England. The *Weekly Weather Report* of the 7th instant showed that the temperature in the eastern and midland parts of England was 12° to 13° below the average for the week; at several of the inland stations in England the daily maxima were below 32° through the whole period.

An enlightened Bengali, Babu Govind Chandra Laha, has contributed fifteen thousand rupees towards the expenses of the proposed snake laboratory at Calcutta. We may expect, therefore, that the institution will soon be in full working order. According to the *Pioneer Mail*, two main lines of research will be followed in the laboratory. So-called cures for snake-bites will be tested under strictly scientific conditions, and the properties of the snake poison as such will be investigated. The laboratory will be the only institution of its kind in the world, and the Committee of the Calcutta Zoological Gardens, who have taken the matter in hand, expect that it will be largely resorted to by the scientific inquirers who visit India during cold weather. In accordance with the practice of scientific laboratories in Europe, a charge will be made for the use of the tables and instruments at a rate sufficient to cover working expenses. Work done on behalf of the Government will also be charged for according to a regular scale.

The members and friends of the Society for the Study of Inebriety met on Tuesday to congratulate Dr. Severin Wielobycki on having completed one hundred years of life.

Prof. Bain contributes to the new number of *Mind* an interesting sketch of the career of the late Prof. G. C. Robertson, with whose name *Mind* will always be intimately associated. Prof. Bain includes in his article the admirable notice of Robertson written by Mr. Leslie Stephen for the *Spectator*.

We are glad to note the publication of a fifth edition, revised and augmented, of the Official Guide to the North Gallery at the Royal Gardens, Kew. It includes a short and interesting biographical notice of Miss North. A map is given to convey some idea of the extent to which her collection illustrates the vegetation of the temperate and tropical regions of the world.

A new edition of the list of members of the Institution of Civil Engineers, corrected to the 2nd inst., the seventy-fifth anniversary of its establishment, shows that the aggregate number of all classes is 6341, an increase during the past year at the rate of 3½ per cent.

A psychological laboratory has been established at Yale College, where Prof. Ladd has for some years been lecturing on physiological psychology. *Science* gives an interesting account of the new institution, which has been placed under the charge of Dr. E. W. Scripture, a pupil of Wundt. The laboratory consists of fifteen rooms, three of which, including an "isolated" room, are given over entirely to research. The isolated room is a small room built inside of another room; four springs of rubber and felt are the only points in which it comes in contact with the outer walls. The space between the walls is filled with sawdust as in an ice-box. The room is thus proof against sound and light, and, according to *Science*, affords an opportunity of making more accurate experiments on the mental condition than any yet attempted.

Students of ethnography will be interested to hear that Dr. N. B. Emerson, of Honolulu, is preparing a full account of the Polynesian canoe. In a communication printed in the new number of the Journal of the Polynesian Society he points out that the various migrations of the ancient Polynesians and their progenitors, from whatever source derived, must have been accomplished in canoes or other craft, and that the *waa*, the *pahi*, &c., of to-day, however modified they may be under the operation of modern arts and appliances, are the lineal descendants of the sea-going craft in which the early ancestors of the Polynesians made their voyages generations ago. He holds, therefore, that a comparative study of the canoes cannot fail to shed light on the problems of Polynesian migrations and relationships.

An interesting little paper on the destruction of wild birds' eggs, and egg-collecting, is contributed to the new number of the *Annals of Scottish Natural History*, by Col. W. H. M. Duthie. Collectors who require to be specially dealt with he groups in three classes—the aimless, the greedy, and the mercenary. In contrast with these is "the true collector," whom Col. Duthie defines as "a naturalist, acquainting himself with birds, their habits, flight, migration, language, and breeding haunts; his egg-collecting being only one of the means of acquiring this knowledge." The true collector should collect for himself, and should never receive an egg into his cabinet unless authenticated by an individual in whom he can implicitly trust. If all collectors were of this type, egg-dealers would cease to exist, and with them would disappear the tribe of hangers-on whom they maintain.

A good study of the form of eggs has been recently made by Dr. Nicolsky of St. Petersburg. He constructs an abstract formula, by which different eggs can be compared without regard to absolute dimensions. Calling the longer axis 1000, he obtains a figure representing the ratio of the longest transverse axis to it, and another, that of the distance of the obtuse end from the "centre," or point where the longer axis cuts the plane of the equator; then forms a fraction with these two figures, and takes it as the formula of the egg. Various explanations have been offered for the different forms of eggs. Dr. Nicolsky traces all to gravity. He considers that every egg not yet coated with a solid shell departs from the spherical form and elongates, simply because of pressure on it by the walls of the ovary. In birds which keep a vertical position when at rest (such as the falcon and owl) the soft egg becomes short through the bird's weight acting against the ovarian pressure. In birds which, like the grebe, are nearly always swimming, the egg lengthens, because the body weight acts in the same direction as the ovarian compression. Lastly, eggs become pyriform (more pointed at one end than the other) in birds which, like the guillemot, often change their position, sometimes swimming and diving, sometimes perching on rocks, &c. An examination of all the eggs in the zoological collection of the St. Petersburg University fully bore out these views. Dr. Nicolsky thinks it would be useful to test the theory by experimentation, birds being kept in a vertical or horizontal position at the laying time.

FOR twelve years (1878 to 1890) M. P. Plantamour made careful observations of the displacements shown by two spirit levels (one north-south, the other east-west), in the cellar of his house at Sécheron. The instruments were transferred to the Geneva Observatory, and the work resumed by M. Pidoux in April 1891 (after six months' interruption). M. Plantamour found that the mean air temperature had a preponderating influence in the oscillations observed, while some other factors of obscure nature were involved. The first year's data at Geneva (*Arch. de Sci.*) reveal an annual oscillation of the ground of the Observatory about an axis directed north-east and south-west, such that the south-east part sinks in summer and rises in winter. The east side went down till July 16, then rose gradually till the end of December (29), thereafter sinking again. The extremes were $-4''\cdot73$ and $+4''\cdot85$ (an amplitude of $9''\cdot58$). The variations of the south side were similar, but the amplitude somewhat greater. The north-south level showed some quite abnormal variations in the autumn of 1891, to which, however, the author does not attach great importance.

AN interesting contribution to our knowledge of the adaptation of structure to function in the human body is afforded in an investigation by Signor Minervini (of the Naples Society of Naturalists) of the blood-vessels of the skin in different parts. Portions of skin were prepared so as to show the exact structure of the chief arteries in them. The results are as follows:—(1) The artery-walls of the skin in men are generally thicker than those of other organs. (2) This greater thickness is due generally, and during most of life, to thickening of the middle layer; but in childhood the outer, and in advanced years the innermost, layer is most developed. (3) The artery-walls in the hollow of the hand, the finger-tips, and the sole, are, other things equal, thicker than those in the back of the hand, the forehead, the arm, &c. This greater thickness is due chiefly to a greater development of the middle layer, and in all ages of life. The arteries in the hollow of the hand in the case of occupations involving hard manual labour show a greater increase of thickness than in the case of those with little or no such work. In these cases all three layers of the artery are thickened, but the middle layer most. (4) In women all the chief arteries of the hollow of the hand and of the back of the hand are somewhat less thick than in men. The difference is not great, but occurs at all ages.

IN a paper on the Santa Isabel Nitrate Works, Toca Chile, read lately before the Scottish Institution of Engineers and Shipbuilders, and now printed in the Institution's Transactions, Mr. G. M. Hunter has something to say regarding the origin of "caliche," as nitrate of soda is called in its native state. Some contend that "caliche" is a marine deposit, others that it is an animal deposit, while others say it is a vegetable deposit. Mr. Hunter holds the first of these views. The coast of Chile has several times been disturbed and upheaved by volcanic agency, and he suggests that a large tract of sea was enclosed and heaved up to the present height of the nitrate region, and there formed an inland sea, which, after a lapse of time under a tropical sun, evaporated, leaving the salts to percolate and form the beds of nitrate. From the formation of the ground, showing depressions and ravines leading to the sea, it is evident that immense volumes of water at some remote period have passed through them. In proof of this, Mr Hunter points out that no "caliche" is ever found in such places, the accepted opinion being that there has been a "wash out," as it is called. During a later period than that of the formation of the "caliche" great floods passed over the plains, as is shown by the deep tracks of rivers, and the smooth washed appearance of the surface. Such periodical floods are common in tropical, rainless regions, and would not call for special remark, but from the fact that wherever these river tracks or washed surface appear no "caliche" can be found. This is so well known that even the workmen never attempt to search for it in such places. The only surface indication for the presence of "caliche" is rising ground covered with small black stones. The "caliche" in its native state is white, very compact and amorphous, not unlike rock salt, but when rich in iodine it assumes various colours, according to the composition and quality of the iodine it contains. For example, at times it contains masses of bright yellow, red, or blue, and again wholly composed of a dull black colour, in which state it requires an expert to distinguish it from *costra* or rock.

MR. E. LOMMEL claims to have found a simple explanation of the Hall effect. A simple train of reasoning shows, he says, that the equipotential lines perpendicular to the lines of flow in a plate are also the lines of force due to the current. If iron filings are strewn upon the plate they will arrange themselves along the equipotential lines if the current be strong enough. On bringing the plate into a magnetic field these lines of force change their position. Hence the lines of flow, necessarily orthogonal to the lines of force, will also change in form and position.

ACCORDING to Dr. J. Böhm, the statement that *Phytophthora infestans*, the fungus which causes the potatoe diseases, hibernates in the tubers, is incorrect, nothing whatever being known about its mode of hibernation. He further states that the infection of the potatoes never takes place in the soil through the uninjured skin, but is always brought about through injury to the tubers by insects or snails. In potatoe-heaps sound tubers can never be infected by their diseased neighbours. An infected potatoe either does not germinate at all or produces a healthy plant.

IN examining milk which is suspected to contain the tubercle bacillus it is usual to subject a sample of the milk to the action of a centrifugal machine after separating the fat. One method of working is described by Ilkewitsch (*Münchener med. Wochenschr.* 1892). The casein in 20 c.c. of milk is coagulated with citric acid, and, after filtering, the residue is dissolved in a solution of sodium phosphate. The butter-fat is separated by shaking with 6 c.c. of an aqueous ether solution, and acetic acid is then added until the liquid is on the point of coagulating. It is then placed in a copper tube tapering at the bottom, and this tube is inserted in the centrifugal machine and turned at the rate of 3600 revolutions per minute for fifteen minutes. The bacilli collect at the narrow end of the tube together with other sediment and dirt. The liquid is poured off, and the sediment examined microscopically. Thörner (*Chem. Ztg.* 1892, pp. 791–2) gives another method, which is as follows:—20 c.c. of the suspected milk are mixed with 1 c.c. of 50 per cent. potash solution, and heated in a bath of boiling water until the fat is saponified, when the solution turns yellowish brown. By this treatment the casein and albumen become soluble in acid. Twenty cubic centimetres of acetic acid are added, the solution shaken, heated on water-bath for three minutes, transferred to a strong glass tube, and turned in the centrifugal machine for ten minutes. The liquid is poured off, and the sediment is washed by shaking with 30 c.c. hot water, and again turned in the centrifugal machine. The water is poured off, and the sediment placed upon cover-glasses, which are treated in the ordinary way, staining with hot Neelsen's solution, decolourizing in 25 p.c. sulphuric acid, and finally staining in methylene blue; instead of washing the cover-glasses in sulphuric acid Thörner simply uses a solution of methylene blue containing sulphuric acid.

A METHOD of producing an intense monochromatic light is described by Dr. Du Bois (*Zeitschr. für Instr.* p. 165). It differs from the usual processes in the form in which the sodium is introduced into the flame. A mixture of sodium bromide and bicarbonate is made cohesive by adraganth and moulded into sticks 4 mm. in diameter and 12 to 15 cm. long. These are kept in the flame of a Linnemann burner by means of a rack and pinion motion. Their conductivity being very low, they are only vaporized at the extreme end. The latter must be covered to avoid a continuous spectrum. At the greatest intensity, two or three centimetres of the substance are consumed per minute. The spectrum exhibits, besides the enormously preponderating D lines, a pair of lines in the green, and a fainter pair in the red.

FROM the ages of persons who have died in France during the last 32 years, M. Turquan computes the average life there to have been about 38 years for women, 36 for men, and 37 years for both sexes together (*Rev. Sci.*). But this is now exceeded, and the average is over 40 years; a result, partly, of more attention to hygiene, partly of a diminished birth-rate. From a map showing the distribution of the average life, one finds the average very low in Finistère and Brittany (28 years 11 months in the former) in the Nord, the Pyrénées Orientales, &c., and especially in Corsica (28 years 1 month). In Finistère and Corsica one finds least hygiene and most children, but not the highest mortality of children. In some parts of Normandy, with a high infantile mortality, the mean life is yet very long. Thus it is about 48 years in Eure, 47 in Orne and Calvados, &c. The difference between the average life of men and women rises to 4 years (excess in case of women) in the north-west, and diminishes as you come towards the Mediterranean; and in Basses Alpes and Gard (in the south-east) man lives longer than woman by about a year and a half. In Normandy and Brittany there are most widows, and woman appears to have a greater vitality.

IT is now many years since electric currents were proved to exist in plants. In the study of these currents, an important step in advance was taken when Prof. Burdon Sanderson proved their existence in *uninjured* parts of living plants (it was usual before to apply electrodes, often polarizable, to cut parts). As to their cause, certain experiments made by Kunkel, some time ago, led him to think it was in the purely mechanical process of water-motion, set up on application of the moist electrode. The subject has been recently investigated by Herr Haake, who pronounces against this view. He used Du Bois Reymond's clay electrodes, with some woollen fibres projecting at the ends, and he enclosed the leaves in a tube in which they were guarded from air-draughts and kept moist. Arrangements were also made for various operations, such as varying transpiration, admitting hydrogen, removing oxygen, &c. (for details see *Flora*, p. 455, of this year). Herr Haake's results are briefly these:—1. It is unquestionable that changes of matter of various kinds are concerned in the production of the electric currents, especially oxygen respiration, and carbonic-acid assimilation. 2. Water-movements may possibly share in their production, but certainly their share is but a small one.

THE *Isvestia* of the East Siberian Geographical Society (vol. xxiii., 3) contains an account of M. Obrutcheffs' further researches in the Olekma and Vitim highlands. In the north-eastern, formerly quite unknown part of this region, the author found a further continuation of the "Patom plateau"—that is, a swelling from 3500 to 4000 feet high, devoid of tree vegetation, with ridges and mountains rising over it to heights of from 5000 to 5600 feet. They consist of granite and crystalline schists, probably of Laurentian age, covered with younger, probably Huronian, gneisses and schists. The other parts of the highlands consist of Cambrian and Lower Silurian deposits, while Upper Silurian limestones and Devonian Red sandstones are only met with in the valley of the Lena. We thus have a further confirmation of the hypothesis, according to which the great plateau of north-eastern Asia is a remnant of an old continent which has not been submerged since the Devonian epoch. Further traces of mighty glaciation have been found in the south-east part of the region. As to the gold-bearing deposits, they are pre-glacial in the south, and post-glacial or recent in the north. The high terraces in the valleys are indicative of a considerable post-pliocene accumulation of alluvial deposits, and of a subsequent denudation on a great scale.

MESSRS. MACMILLAN AND CO. announce that a new edition of Sir Archibald Geikie's "Text-book of Geology" is in the press, and will appear shortly.

THE third and fourth volumes (completing the work) of Mr. H. C. Burdett's "Hospitals and Asylums of the World" will be published by Messrs. J. and A. Churchill about the end of this month. Vol. iii. deals with the history and administration of hospitals in all countries throughout the world. Vol. iv. relates to hospital construction, and contains a bibliography and portfolio of plans.

MESSRS. R. SUTTON AND CO. have published a second edition of Mr. J. E. Gore's "Scenery of the Heavens," with stellar photographs and various drawings. Mr. W. F. Denning contributes to the volume a chapter on fireballs, shooting stars, and meteors.

THE second annual issue of "The Year-Book of Science," edited by Prof. Bonney, F.R.S., is now in a forward state of preparation, and will be shortly published by Messrs. Cassell and Company.

MESSRS. DULAU AND CO. have published "Annals of British Geology, 1891," by J. F. Blake. This is the second issue, and geologists will be unanimously of opinion that it is a decided improvement upon the first. It contains a digest of the books and papers published during the year, with occasional notes.

LECTURES on the ear will be delivered in Gresham College, Basinghall Street, E.C., on January 17, 18, 19, and 20, at 6 o'clock, by Dr. E. Symes Thompson.

IN Mr. R. Assheton's letter (NATURE, vol. xlvii. p. 176) the sentence beginning line 31 of the second column should have read thus:—"But it is more metazoic—if I may use such a word—to call the whole animal resulting from the segmentation of the fertilized ovum, the sexually produced generation."

TWO interesting new compounds are described by Prof. Anschütz, of Bonn, in the current number of the *Berichte*. They are well-crystallized compounds of the lactides derived from salicylic acid and the next higher (cresotinic) acid with chloroform, which latter substance is so loosely united with the lactide that warming to the temperature of boiling water is amply sufficient to dissociate them. Hence the compounds may be employed for obtaining perfectly pure chloroform, and for preserving chloroform in a solid form in which it is not prone to decomposition. The lactide of salicylic acid has long been supposed to be formed when the acid is treated with oxychloride of phosphorus. Prof. Anschütz, however, shows that the product of this reaction contains many other substances in addition, but by working under special conditions he has succeeded in isolating pure salicylide. Salicylic acid is dissolved in an indifferent solvent, preferably toluene or xylene, before the addition of the phosphorus oxychloride. The product of the reaction is washed first with soda and afterwards with water. Owing to the property, discovered by Prof. Anschütz during the course of the work, which salicylide possesses of combining with chloroform, it may be extracted from the white solid product, after drying, by means of chloroform, the compound being deposited from the chloroform solution in large colourless transparent crystals belonging to the tetragonal system. The compound possesses the composition $C_6H_4.CO.O.2CHCl_3$. The chloroform readily escapes upon warming, in very much the same manner as the water of crystallization contained in many crystallized salts. The free salicylide remaining is a solid substance melting at 261°. As regards its molecular constitution it is shown, by the amount of lowering of the melting-point of phenol employed as a solvent, to contain four of the salicylic radicles $C_6H_4.CO.O$, and is probably a closed ring compound. In a precisely similar manner phosphorus oxychloride reacts with the three cresotinic acids, the acids next higher than salicylic, with formation among other substances of lactides, which may be isolated in the same way in the form of their chloroform compounds, $CH_3.C_6H_3.CO.O.2CHCl_3$. Orthocresotinic acid lends itself best to this reaction. The pure lactides are readily obtained from the chloroform compounds by warming to 100°, pure chloroform being gently evolved.

THE two substances above described, salicylide-chloroform and the corresponding compound derived from ortho-cresotinic acid, are admirably adapted for the preparation of pure chloroform, on account of their large content of the latter substance, salicylide-choloroform containing 33·24 per cent. and the cresotinic compound 30·8 per cent of its weight. Moreover, in closed vessels they may be preserved any length of time; when exposed to the open air salicylide-chloroform slowly loses its chloroform, but the cresotinic compound is well-nigh stable, even under these conditions. The same quantity of the free lactide may be used over and over again without decomposition, it being only necessary, in order to re-form the chloroform compound, to allow it to remain in contact with the chloroform to be purified for twenty-four hours at the ordinary temperature. None of the usual impurities in chloroform crystallize along with the compound, so that a perfect separation is effected. Again, it is well known that pure chloroform decomposes more or less on keeping; this loss may be avoided by storing it in the form of the lactide, and regenerating it when required by the application of a gentle heat, with the certainty of obtaining it perfectly pure.

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (*Macacus rhesus* ♀) from India, presented by Mr. W. Stutely; two Barbary Mice (*Mus barbarus*) from North Africa, presented by Lord Lilford; four Bearded Titmice (*Panurus biarmicus*), European; four Ani (*Crotophaga ani*) from South America; six Hog-nosed Snakes (*Heterodon platyrhinos*); a Striped Snake (*Tropidonotus sirtalis*); a —— Snake (*Pitnophis* ——), from North America, purchased.

OUR ASTRONOMICAL COLUMN.

THE MOTION OF NOVA AURIGÆ.—Prof. W. W. Campbell, of the Lick Observatory, has communicated further results relating to Nova Aurigæ to the December number of *Astronomy and Astrophysics*. He is now perfectly convinced that the variation in the velocity previously suspected is real, and probably due to orbital motion. The values given below have been calculated on the assumption that the brightest line in the spectrum of the Nova, since the reappearance in August, is really the chief nebula line. The bright lines were displaced towards the violet, indicating approach, whereas in February and March last they were displaced towards the red.

Date. 1892.		λ		Velocity of approach. Miles per sec.

3	...	4·7	...	87

In the same journal Mr. Sidgreaves points out that the new lines cannot simply be revivals of those of February, and, further, that on account of the great difference of velocities and the reversed direction, they cannot be supposed to belong to the bright-line component of February. Neither is it likely that the dark-line component has become a planetary nebula, and the probability of three bodies rushing together being very small, Father Sidgreaves believes the new results to strengthen the view that the compound character of the spectrum was produced by local disturbances of a single star.

ASTRONOMICAL DISCOVERIES IN 1892.—In the *Observatory* for January Mr. Denning gives an excellent summary of the astronomical discoveries of 1892, a year which was very remarkable for the special attention given to the science by the press and the public. In chronological order the principal events were as follows:—

January 20.—Minor planet (324) discovered by photography by Max Wolf at Heidelberg. (Altogether 27 were discovered during the year by various observers.)

January 23–30.—Discovery of Nova Aurigæ by Dr. Anderson.

February 11.—The great sun-spot, extending over 150,000 miles of longitude, reached the sun's central meridian. This was followed by remarkable magnetic disturbances and displays of aurora.

March 6.—Comet discovered by Lewis Swift.

March 18.—Comet discovered by Denning at Bristol. On this day also, Dr. Spitaler, of Vienna, re-detected the periodical comet of Pons (1819) and Winnecke (1858).

August 6.—Opposition of Mars. Mr. Denning writes: "Practically our knowledge stands where it stood before. The results are not sufficiently discordant to settle disputed points."

August 27.—A new comet discovered by Brooks, of Geneva, N.Y.

September 9.—Prof. Barnard's memorable discovery of the fifth satellite of Jupiter.

October 12.—Comet discovered by photography by Prof. Barnard.

November 6.—Bright comet discovered in Andromeda by Mr. Edwin Holmes, London.

November 20.—A faint comet discovered by Brooks.

November 23.—Brilliant shower of shooting stars observed in Canada and the United States. The shower was evidently that of the Andromedes connected with Biela's comet.

COMET HOLMES.—Mr. Lewis Boss finds for this comet a period of 6·914 years, and concludes that no very close approach to Jupiter can have taken place in recent years; the eccentricity, however, is so small that important perturbations by Jupiter may have occurred. He further states that "the recent remarkable decrease in brightness of the comet seems to do away with the necessity of supposing that it has been recently made a member of the solar system. This decrease also renders it reasonably certain that the comet must have been subjected to some extraordinary disturbance of its internal economy, by the application of forces from without or within, with the result of giving to it that which was really an unaccustomed and temporary size and brightness" (*Astronomical Journal*, No. 283). According to Mr. Lockyer's views, such increase of brightness would be produced by the comet colliding with another meteor swarm lying in its track, and it is quite possible that the brightening of the comet at the time of the discovery was very sudden, thus explaining why the comet was not detected earlier.

The Rev. E. M. Searle (*Astronomical Journal*, No. 283) has deduced a period fifteen days shorter than that of Mr. Boss.

M. Schulhof, of Paris, finds a period of 6·909 years. He also points out that among the known periodic comets that of De Vico shows the greatest orbital similarity to Holmes's comet, and he considers that they may possibly have a common origin.

Mr. Roberts, of the Nautical Almanac Office, accepting as real the supposed impression of the comet obtained by Mr. Schorling in a photograph of the region taken on October 18, found a period of fifteen years, but the general agreement of the latest computations seems to indicate that the image in question could not be that of the comet.

The comet is now so dim that it is not considered necessary to continue the ephemeris.

EPHEMERIS OF COMET BROOKS (November 20, 1892).—The following ephemeris of Comet Brooks (Berlin, midnight) is given in *Ast. Nach.*, No. 3140, by Kreutz :—

Date.	R A.	Decl. (app.)	Log r.	Log Δ.

THE METEOR SHOWER OF NOVEMBER 23, 1892.—Further observations of this fine display of shooting stars are recorded in *Astronomical Journal*, No. 283. Prof. J. K. Rees counted 165 meteors in half an hour, and noted some as bright as Mars; all of them were very swift. The Rev. J. G. Hagen estimated that one observer, with a clear view to the west would have seen 250 meteors in half an hour, and notes that some were as bright as Jupiter. Mr. Sawyer estimated the maximum frequency as about 300 per hour, and, strangely enough, describes them as "slow-moving, generally quite bright, although none were observed as bright as the planets Mars and Jupiter." Both Prof. Rees and Mr. Sawyer note that the meteors appeared in clusters, four or five falling almost at the same instant, while for a few minutes none were seen. The radiant was near γ Andromedæ, and there is little doubt that the shower was that due to Biela's comet.

GEOGRAPHICAL NOTES.

IN M. Dybowski's journey from the Mobangi to the Shari, as described at a recent meeting of the Paris Geographical Society, he encountered one of the most systematically cannibal tribes which has yet been described. This tribe, known as the Bonjos, have only one object of purchase—slaves to be eaten. They refuse to sell food or any other products of their country for anything else, and the surrounding tribes capture and export canoe-loads of slaves for this purpose. The French expedition experienced great difficulty in obtaining food amongst a people who had no desire for ordinary articles of trade.

THE boundaries of the republics of South and Central America are certainly the least definite lines on the political map of the world so far as civilized lands are concerned. The question of delimitation is never at rest. Dr. H. Polakowsky gives in the last number of *Petermann's Mitteilungen* a brief account of the negotiations and surveys relating to the frontier of Costa Rica and Nicaragua from 1858 to 1890. The difficulty in this case lies in the fact that the mouth of the San Juan river, a certain point of which was fixed on in 1858 as the coast frontier, is continually changing, and a breakwater belonging to the harbour and canal entrance of Greytown, in Nicaragua, now stands in what was formerly the territory of Costa Rica. On the Pacific coast years of diplomacy were required to fix the centre of Salinas Bay, but it is satisfactory to know that permanent boundary stones have now been erected at both ends of the line.

MR. COLES delivered his second lecture to young people under the auspices of the Royal Geographical Society, on Friday evening, when a large audience of both young and old enjoyed his spirited descriptions of Iceland and British Columbia, illuminated by many anecdotes of personal adventure.

THE defective condition of the charts, even of the coast of Europe, was strikingly brought out by the recent court-martial on the stranding of H.M.S. *Howe* in Ferrol Channel. The chart used on board was drawn from soundings made about a hundred years ago, with a few subsequent corrections, which failed altogether to indicate the rock on which the *Howe* struck. The Spanish authorities are reported to have refused permission for the new chart surveyed by the officers of the Channel Squadron to be published, and meanwhile the Hydrographic Office has cancelled the old chart.

A NEW SEISMOGRAPH.

BEFORE speaking of this memoir, let me enter a protest against the method of publishing these "Annali" in such a way as to convey the impression that the papers composing it were written three years before their actual date. All readers are warned that when the volume is bound up, and the paper covers are removed, they must post-date the papers by three years.

The seismograph described in the present paper is intended for stations of the second class. The objects in view in its construction were amplification of the record in a pendulum seismograph, and improvement of the warning apparatus in the form of a style seismoscope of the Milne type which the author finds frequently fails.

The amplifying lever is composed of fine placfont tubes arranged girder-like in the form of a short hollow triangular prism, surmounted by an acute triangular pyramid, which points downwards, and carries at its apex the writing style. The pendulum bob is a flattened cylinder, supported by a placfont wire 1·50 m. long. The amplifying lever at the junction of the three pyramidal and the prismatic tubes supports three radial arms meeting in the centre, as it were, of the pyramid base, and support a ball-and-socket joint of agate, the cup part of which is at the end of an arm projecting from the supporting wall. Immediately above this centre, and occupying the prism space of the lever, is the cylindrical box, the wire supporting which passes through a small hole in the centre of the base of the prism. We thus have a simple lever of the first order of light girder work. It is prevented from rotating in azimuth by including some steel wire permanently magnetized.

The style has been modified by lightening it and making it more rigid and non-oxidizable, which is done by using a capillary glass tube.

The registering apparatus is a smoked glass plate, supported over a clock, started at the moment of the earthquake by a seismoscope. To prevent the complex figures of the ordinary registration in a pendulum seismograph, the author has arranged so that the plate shall rotate through a segment of a circle every three seconds, so as to bring a fresh surface of smoked glass beneath the style.

Some modifications are then described. The principal one is making the bob annular, carrying a suitable aperture, in which is engaged the short end of a lever. This lever is composed of three very thin brass tubes, graduating away smaller from the fulcrum, which is a gimbal joint such as suggested by the reviewer some years since in NATURE. This lever carries at its lower and longer end the style which records on the glass plate as in the original one described in this memoir.

Another modification is a combination of the triple and single suspension of the pendulum bob, that is, the bob ring is first suspended by triple wires to a button which in its turn hangs at the end of a single wire.

The details of these seismographs are fairly well worked out, but the employment of aluminium in many of the parts has been neglected. Likewise, no arrangement has been made for the oblique play of the engaged pinion in the newer lever. The only new point about this seismograph is the interrupted rotation of the recording plate. This has a decided advantage in giving a dissected record, but is part counterblanced by the fact that important movements that may be taking place at the moment

---

[1] G. Agamennone, "Sopra un Nuovo Pendolo Sismografico." *Annali dell' Ufficio Centrale Meteor. e Geodinamico*, ser. sec., pt. 3, vol. xi., 1889. (Roma, 1892.)

of the advance are represented by a curve or curves which would require a series of careful experiments to be carried out in each instrument, followed by difficult and elaborate calculation for each advance.

Much credit is due to the author for working out the modifications, but until we have some original method of finding a steady-point, not so far suggested, it is doubtful if we can improve on the Gray, Ewing, and Milne seismographs, that are not, as the author imagines, little used or tested instruments.

H. J. JOHNSTON-LAVIS.

PHYSICAL GEOGRAPHY AND CLIMATE OF NEW SOUTH WALES.

A SECOND edition of an excellent pamphlet on the "Physical Geography and Climate of New South Wales," by Mr. H. C. Russell, F.R.S., astronomer royal for New South Wales, has just been issued at Sydney. It is published by authority of the New South Wales Government. The following extracts may be of interest to various classes of readers in Great Britain:—

Looking back through the pages of history, and the dim traditions of an earlier time, we find abundant evidence of a belief in the existence of a great south land to the south and east of what was then the well known earth. Those early navigators whose travels had fostered this belief, had doubtless followed down the Malay Peninsula and the string of islands which seem to form part of it, in search of spices and other treasures which the islands supplied. Pliny, who had evidently gathered up the traditions of "Terra Australis incognita," says that it lay a long way south of the Equator, and in proof of this mentions the fact, strange in those days, that when some of its inhabitants were brought to civilization they were astonished to find the sun rise on their left hand instead of on their right. And Ptolemy, A.D. 170, after describing the Malay Peninsula, says: Beyond it, to the south-east, there was a great bay in which was found the most distant point of the earth; it is called "Cattigara," and is in latitude 8½° south; "thence (he goes on to say) the land turns to the west, and extends an immense distance until (as he believed) it joins Africa." And it may fairly be assumed that the extreme south latitude of Cattigara, and its situation in a great bay where the land turns to the west until it joins Africa, is proof that it was some point in the Gulf of Carpentaria, for no other place would fulfil the conditions. The idea that the land actually reached Africa was not Ptolemy's; it was a necessary part of the system of Hipparchus, for he taught that the earth surrounded the water and prevented it from flowing away. It is not surprising, therefore, that the early navigators, following down the islands, came at length to that part of the Gulf of Carpentaria where the land turned to the west; and believing Hipparchus' system of geography, thought that in turning to the west they were in reality turning towards home, and Cattigara was therefore the most distant point known. Marco Polo tells us that the Chinese navigators in his day (A.D. 1293) asserted there were thousands of islands in the sea to south of them, and in the present day we find proofs of their early visits to Australia in the traces of Chinese features amongst the natives of the northern coast; indeed, some historians think that Marco Polo, in the account he gives of the expedition sent to Persia by the Great Khan, refers directly to Australia, under the name of Lochac. This place he says was too far away to be subjugated by the Great Khan, and was seldom visited; but it yielded gold in surprising quantity, and amongst other wonders contained within it an immense lake or inland sea. It is impossible that such a description should apply, as has been thought, to the Malay Peninsula,—a country within easy reach, and one which his ships must have passed in every voyage; and so far from being beyond his power, it was within the limits over which his sway extended. That Lochac formed part of the main-land was also quite in accordance with their ideas of the earth, which surrounded the ocean, and the abundance of gold is certainly more likely to be true of Australia than of the Malay Peninsula.

For long years after Marco Polo we find no direct reference to Australia, except the stories which lived amongst navigators, and seemed to lose none of their marvellous points by transmission. These kept alive the desire to explore the great south land, so rich in treasures and wonders. All the evidence collected so far goes to prove that the Portuguese had, early in the sixteenth century, explored at least the northern parts of Australia. What they learned was, however, kept a profound secret until about 1540, when one of their government maps was stolen; and there are now in existence six maps believed to be copies of it, which were all published between 1539 and 1555. These all show Australia under the name of the "Land of Java," the real Java being called the "Little Java," and from this time onward frequent attempts were made to explore what had for so many generations been "Terra Australis incognita." Sturdy navigators could not understand the silence of the Portuguese, except as proof of the richness of the land, about which tradition told wonderful tales. "It was a land of gold and spices, of magnificent tropical fruits and vegetation—a perfect paradise, in which the happy and simple inhabitants were loaded with jingling ornaments of gold. Its very atmosphere was elixir, and existence a round of enjoyment." No wonder that in an age when, at least upon the ocean, the power to take was mistaken for the right to do so, there were many who cast longing glances towards the southern Paradise. Whether these stories of gold had any foundation in fact or not, when barter was regularly exchanged on the coast of Australia, it is impossible now to say, but more recent discoveries of rich surface gold lend some colour to them, and the vegetable richness of the northern part of Australia is quite in accordance with tradition. But all the early English navigators were unfortunate, and Australia got a reputation the very reverse of what further investigation has shown that it deserves. In point of fact, all the glowing colouring of tradition is true; but when Dampier, in 1688, sailed down the western coast, he saw nothing but a "dry sandy soil," and the "miserablest people in the world"; and later on, when the first English settlers landed on Australia, they chose a bay, beautiful to look at, but there was no gold and no fruit worthy of the name, the soil was barren and sandy, and the climate in the worst part of its summer. No wonder that the fame of Australia was blackened, and report made it a miserable land, subject to droughts and floods—a land in which everything was turned topsy-turvy. The summer came at winter time; trees shed their bark, not their leaves—were brown instead of green; the stones were on the outside of the cherries; and the pears, pleasant to look at, were only to be cut with an axe; and there was nothing to eat, "unless, perchance, ye'l fill ye with root of fern or stalk of lily." Such was the early verdict upon Australia. Fortunately the first colonists, once here, were obliged to stop. By degrees they found that everything that was planted grew well; that wheat in the valley of the Hawkesbury yielded 40 to 50 bushels to the acre, and in one memorable season actually ruined the farmers by its very abundance, for in the then limited market, the price fell so low that it was not worth gathering, and it was left in the fields to rot, while the farmers sought other work. Horses, sheep, cattle, and pigs throve marvellously, and some of the cows getting away, the bush soon contained numbers of wild cattle. Even wool did not deteriorate in the new Colony; and step by step the facts became too strong for prejudice, and the first fleeces of Australian sheep sent to England lifted the veil. Manufacturers would gladly take as many as could be sent; their demand for more wool extends with the supply, and now only from Australia can they obtain the fine wools which they need. Quantity and quality of wool have increased together, and the Grand Prize at the Paris Exhibition for our New South Wales wool has proclaimed the fact far and wide. Wool has done still more for the Colony. We took possession of it as a narrow strip of coast country; the demand for pasture forced us to find a way over a hitherto impassable range, and the same want has driven all the desert out of the Colony, and covered it with sixty-two millions of valuable sheep (1892). The country which early writers upon Australia called a barren waterless desert is now growing the finest wool and yielding abundant water from wells, and when, in 1851, it was announced that gold had been discovered in abundance, the world was convinced that Australia was a promising country after all. Year by year the people have been coming in increasing numbers to supply our great want (population), and as our numbers increase new avenues of wealth and prosperity are opening before us.

Geographically, Australia has a grand position, lying between the 10th and 40th degrees of south latitude—that happy mean where it is neither too hot nor too cold. Surrounded by the ocean, the sea breezes temper what might otherwise be a hot climate in the summer; the air is clear and dry, and yet brings rain in heavy showers. Vegetation is abundant, and includes all the cereals and fruits of the world, so that, in the words of the old tradition, it has "all the conditions which make life a pleasure."

Australia measures from north to south 1900 miles, and from east to west 2400 miles, and speaking generally, has a rounded outline, the only great inlets on the coast-line being the Gulf of Carpentaria and the Australian Bight. The total area is rather greater than that of the United States, and almost equal to the whole of Europe. On the east, north, and west, and at a short distance from the coast are found ranges of mountains, of no great elevation, yet almost the only high land. On the west and north-west coasts the mountains form a bold outline of granite, rarely more than 200 miles from the coast, and attaining to heights of 2000 to 3000 feet. Between these and the sea the land is low and good, but on the inland side is found a vast table land which slopes towards the unknown interior so gradually that the inclination is not easily seen, and no rivers running to the interior have yet been discovered—all known streams running to the sea.

On the east coast we have also the mountain chain parallel to the coast, but it is much higher and more extensive, and the strip of low land by the coast is much narrower, often not more than 30 miles wide, and at Point Danger the range comes right to the sea. This grand chain of mountains is known generally as the Great Dividing Range, and extends for about 1500 miles along the east coast. Near its southern extremity is the Snowy Range, the only spot in Australia where snow may always be found. The highest peak, Mount Kosciusko, 7170 feet, is also the highest land in Australia. The ravines on its sides always contain snow, and the mountains near it, about 6000 feet high, are also covered with snow for the greater part of the year.

Of this great continent island, the Colony of New South Wales holds the choicest portion—the southern part of the east coast—the part where, with remarkable sagacity, the first settlement was made. It has the best climate, all the most important rivers in Australia, the great bulk of the coal land, unlimited stores of all the useful minerals, and the finest pastoral and agricultural lands for extra-tropical vegetation; besides which, its extensive highlands afford climatic conditions for all purposes. It is naturally divided into three portions. The comparatively narrow coast district, from 30 to 150 miles wide, abundantly watered by rivers and smaller streams coming down from the mountains. The rainfall here, fed by winds from the Great Pacific Ocean, is very abundant, from 40 inches in the south to 70 in the north, and at Sydney 50 inches. The mountains have doubtless very much to do with this abundant precipitation, and at times the rains are so heavy that the rivers, fed by mountain torrents, carry heavy and dangerous floods. In years past wheat was largely and profitably grown, but rust has of late so frequently appeared that little or no wheat is grown, for it pays better to supply the city markets with dairy produce, Indian corn, and various kinds of hay. In the northern districts sugar-growing is a profitable industry, and increasing rapidly. About Sydney enormous quantities of oranges are grown for exportation.

The second division includes the mountains and elevated plains, and extends the whole length of the colony, varying in width from 120 to 200 miles. On the south, with the exception of the Monaro Tableland, the country is very rough and mountainous, the highest points, Mount Kosciusko and the Snowy Range, catch the rain and snow that feed the river Murray and the Murrumbidgee. Wheat grows well here, but nearly all the land is used for pastoral purposes. Proceeding northwards, the mountains decrease in height and extend laterally. A part of the land is taken up for agriculture, some for mining. In its natural state the western country is open plain or lightly-timbered, and large areas are covered with rich volcanic soil which seems fit to grow anything, but the want of labour and carriage, and the profit and security to be found in raising wool and meat, has for the most part tempted capital into squatting pursuits; but since the railway has reached this part of the country more attention is being given to agriculture, and it is rapidly extending. Between Goulburn and Bathurst, the western waters form the Lachlan and the eastern the Hawkesbury rivers, and from Bathurst northwards to latitude 25° all the western waters go to form the various tributaries of the Darling river. These mountains are from 2000 to 3000 feet, with some peaks rising to nearly 6000 feet. The central parts of the western slopes are celebrated for rich soil and herbage, and here also the greater part of the gold-mining area, as well as mines for other minerals have been found, including coal, which is also found in great abundance, with iron and lime, at Lithgow and other places. Deposits of copper, silver, lead, tin, and mercury are also found in abundance. A very large portion of the high land here is suitable for agriculture, and is being taken up for that purpose by degrees. English fruits—the apple, cherry, currant, &c.—grow to perfection here, as well as in other parts of the mountain districts.

The third division covers by far the greatest area, and consists of the Great Western Plains, extending away to the Darling river, and thence to the south Australian border. Here there are but few known mineral deposits except copper, and the enormous deposits of silver and lead at Broken Hill, and no attempt at agriculture. All the land may be said to be held for grazing purposes, and for that purpose, now that capital has been invested in tanks and wells for water supply, this country is unequalled. Sheep and cattle thrive in a remarkable degree, and form a most profitable investment, the climate being dry and wonderfully healthy for man and beast.

These are the three great natural divisions, made so by the conformation of the land and the climate. It will be evident from what has been said of the elevation of the mountains that snow is not a common feature upon them, and the only part where snow lies for any considerable time is the extreme south. As a necessary consequence, the river system is peculiar; indeed, it has often been asserted that Australia had no rivers—at least none which were of any use as such; but as we shall presently see, this statement, like many others affecting Australia, was made in ignorance. The necessity for increased pasture had driven the early colonists to cross the Great Dividing Range, aptly so-named, in search of pasture, in 1815, and the desire to extend the new pastures beyond the Bathurst Plains, which were the first discovered, led them on, and one of the first questions that demanded their attention was to account for the direction in which all the streams were flowing. The shortest road to the sea was to south-west, and yet all the water was running to north-west, and quite naturally it was asked—Could there be a great inland sea into which these rivers discharged? In 1818 Oxley started with a determination to see where at least one of them went to; so he followed the Macquarie for more than 200 miles, and found that he was going due north-west, further and further, as it seemed to him, from the natural outlet on the south coast. At last the river spread out to an apparently interminable marsh. Turn which way he would his progress was stopped by a shallow fresh-water sea, for sea he was at last convinced it must be, so great was its extent, and he was obliged to turn back. He had got there after two very wet seasons (1817 and 1818), and his inland sea is now known as the Macquarie Marshes; and the mystery was not solved until Sturt, in 1829, found all these streams trending to north-west unite in the Darling, and then turn to south-west.

Coming from mountains of such moderate elevation, these streams are necessarily dependent upon the rainfall, and have no snow to help them, so that in rainy seasons they become important rivers and in dry ones sink into insignificance; but since most of the rains which feed these waters are, as it were, offshoots of the tropical rains, they seldom fail altogether, and as a rule the Darling is navigable for four months of each year, and sometimes all through the year, up to and beyond Bourke. The current is very slow, seldom reaching two miles per hour, and therefore offers little hindrance to the steamers which carry wool and stores.

In the exploration of our rivers there was another surprise when settlement extended south-west from Sydney. The waters here were found to flow to the west, and the Lachlan has for a considerable portion of its course a south-west direction, that is, at right-angles to the Macquarie and the Bogan. Could the Lachlan, the Murrambidgee, and the snow-fed Murray ultimately join the waters that ran north-west from Bathurst? Sturt had not solved this question—he only followed the Darling part of the way down—and it was left for Sir Thomas Mitchell to find the junction of the two river systems in 1835, and to prove that the Darling and the Murray were united at and below Wentworth.

After dealing with the rivers and harbours of New South Wales, Mr. Russell discusses the temperature, rainfall, droughts, and winds of the colony. Of the temperature he says:—

In works of reference, Australia generally is credited with heat in excess of that due to its latitude. It is difficult to say why, unless it arose from a habit of one of our early explorers who carried a thermometer and carefully published all the high, and none of the low readings he got, until, fortunately for the colony, the thermometer was broken and the unfair register stopped. But not only the interior—Sydney even to the present day is credited, in standard works of reference, with a mean temperature of 66·2°, or more than three degrees higher than the true mean, which is 62·9°. Such an error is not excusable when meteorological observations have been taken and published for just forty years. There is another error made by some writers when describing Australia. It is shown by them inverted on the corresponding latitudes in Europe, and the reader naturally infers that Australia is as hot as those parts of Europe. Confining our attention to New South Wales, that is between 29° and 37° of south latitude, we find that generally it is cooler than a corresponding part of Europe. The mean temperature of the southern parts of England is about 52°, and that of France, near Paris, about the same, increasing as you go south to 58·5° at Marseilles. Taking this as a sample of the best part of Europe, let us see how the mean temperatures in the colony compare with those: Kiandra, our coldest township, situated on a mountain, is 46°; Cooma, on the high land, 54°; Queanbeyan, high land, 58°; Goulburn, high land, 56°; Armidale and New England district, 56°; Moss Vale, 56°; Kurrajong, 53°; Orange, 55°. These towns are scattered along the high table-lands from south to north, and represent fairly the climate of a very considerable portion of the whole colony. Next to this in point of temperature is the strip of land between the ocean and the mountains, and which is affected by the cooling sea-breezes. Here we have a mean temperature ranging from 60° at Eden, the most southern port, to 68° at Grafton, one of the northern ports. Sydney, in latitude 34°, has a summer temperature only four degrees warmer than Paris, which is in latitude 49°. Now the usual difference for a degree in latitude is a degree in temperature, and therefore, if Sydney were as much warmer than Paris as its latitude alone would lead us to expect, its temperature should be 74°, and that is 15° warmer than Paris; but as we have seen, it is only 4° warmer. This single example is enough to prove the comparative coolness of our coast districts. The investigation made during recent years shows that the mean temperature of the whole colony, as derived from forty-five stations scattered over it, is 59·5°, three degrees lower than that of Sydney, or only one degree hotter than that of Paris.

It may be mentioned that the highest shade temperature ever recorded in Sydney was 106·9°, and near Paris a temperature of 106·5° has been recorded.

The third great district, consisting of lower land and plains to the west of the mountains, has a climate considerably warmer in summer than the parts above described, owing to the powerful effect of the sun on land having little forest and little or no wind; but in winter the temperature sinks down much lower than the coast districts, owing to the great radiation; so that the annual mean temperature is not so great as the summer heats would lead one to anticipate. A table has been prepared for the purpose of showing by comparison with many places in Europe and America the temperature of the colony. The places have been arranged in order of temperature, taking for that purpose the mean annual temperature. This shows at once that the range of temperature here is equivalent to that offered by Europe from the north of England through France to Sicily. Such a range is more remarkable, because if New South Wales were placed on the map of Europe according to its latitude it would extend from Sicily to Cairo, whereas when placed by its temperature it stretches as we have seen from Sicily northwards to England. Nor is this all that the table shows us. For even when we find a place in Europe with a temperature equal to that of some place here, it is at once observed that the summer temperature in Europe is warmer than the colonial one and the winter colder; for instance, Naples, 60·3°; Eden, 60·3°; summer at Naples, 74·4°; at Eden, 67·9°; winter at Naples, 47·6°; Eden, 51·9; and so generally the southern country has the cooler and more uniform temperature. It is worthy of remark that the only places here of equal mean and summer temperature with places in Europe are those which are to be found on the western plains, as at Wagga Wagga, which has a mean temperature of 60·3°; Naples, 60·3°; and summer temperature of both is 74°; or again, to compare the places of the same or nearly the same latitude, Messina, in Sicily, latitude 38° 11′, has a mean temperature of 66°, summer 72·2°, winter 55°; Eden, New South Wales, in latitude 37°, has a mean temperature of 60·3°, summer 67·9°, winter 51·9°; or Cairo, in latitude 30°, mean of 72°, summer 85·1°, winter 58·2°; Grafton, latitude 29° 45′, mean 68·1°, summer 76·8°, winter 58·4°. It is useless to multiply examples,—we have here enough to show how much cooler Australia really is than the fervid imaginations of some writers have made it appear in print.

Looking at this question of temperature generally, it will be seen that New South Wales is no exception to the general deduction of science that the southern lands are cooler than those of corresponding latitudes in the north, and it is only during hot winds, which are very rare in New South Wales, that the temperature rises to extremes. But to leave Europe, and compare the climate of New South Wales with that of America. Our limits of latitude would place us from Washington to New Orleans. Now the mean temperature at Washington is 55° and at New Orleans 68°, while that of Eden is 60·3° and Grafton 68·1°; so that if mean temperature were a complete test of climate it would appear that our coast is hotter than corresponding latitudes in America. But mean temperature is not enough; we must compare the summer and winter temperatures; and summer at Washington rises to 76·7° and at Eden only to 67·9°, 9° cooler; New Orleans summer is 82° and Grafton 76·8°; but 82° hardly represents the summer heat at New Orleans, for it is a steady broil, during which every day for three months of summer the heat is over 80°, a temperature that is only reached on this coast during hot winds, or in other words, very seldom. But winter temperature at Washington falls to 37·8°, and at New Orleans to 56°; at Eden 51·9°, and at Grafton 58·4°. Hence it is evident that on this coast the heat is very much less in summer and greater in winter than upon the coast of America. Such facts place the colony in a very different position in regard to climate from that which it has occupied in published works, for instead of being a hot country we see that its coast districts are much cooler than corresponding latitudes in Europe and America, and that in its elevated districts, which comprise a large part of it and much of the best land, it has a climate no warmer than the best and most enjoyable parts of Europe in much higher latitudes; but while bringing these facts into due prominence it is not the intention to deny that another considerable part of the colony, forming the western plains, is subject to greater heat, caused, no doubt, by the sun's great power on treeless plains, and the almost total absence of cooling winds; yet, although in summer the temperature here frequently rises over 100°, and sometimes up to 120°, yet, owing to the cold at night and in winter, the mean temperatures are not greater than those of corresponding latitudes in the northern hemisphere; and this part of the colony being remarkably dry, the great heat is by no means so enervating as a temperature of 80° in the moist atmosphere of the coast, and, what is of still more importance, it does not produce those terrible diseases which are usually the offspring of hot countries. This is also, no doubt, due to the dryness of the air. Stock of all kinds thrive remarkably well, and are very free from disease in those hot western districts.

SCIENTIFIC SERIALS.

THE *Quarterly Journal of Microscopical Science* for August 1892 contains:—On the anatomy of *Pentastomum teretiusculum* (Baird), by Prof. W. Baldwin Spencer, M.A. (Plates i. to ix.). Whilst collecting on Kings Island, which lies to the west of Bass Straits, half-way between the mainland of Victoria and Tasmania, numerous specimens of the copper-head snake (*Hoplocephalus superbus*) were found, in the lungs of which a large species of Pentastomum were parasitic; afterwards the same parasite was discovered in the lungs of the black snake (*Pseudechys porphyriacus*) in Victoria; on examination there seemed little doubt but that the species was the one described by Baird long ago (1862) from specimens obtained in the mouth of a dead copper-head snake in the Zoological Gardens, London, under the name of *Pent. teretiusculum.* In this paper we have a very complete account of the anatomy of this form, there being descriptions and figures of its external anatomy, schematic representations of the muscular, alimentary, secretory, nervous, and reproductive systems, and an account of the sense organs. The paper is illustrated by ten double plates.—On the minute structure of the gills of *Palæmonetes varians*, by Edgar J. Allen, B.Sc. (Plate x.). It would seem that so far as the gills of this crustacean are concerned, the statement made by Haeckel and Ray Lankester, that the circulatory system of the Decapods is everywhere closed, does not hold true. It would also seem fairly certain that the masses of cells surrounding the venous channels, in which Kowalevsky found litmus deposited a few hours after its injection, exercise an excretory function. In addition to these excretory cells, a large number of glandular bodies occur in the axis of the gill, and these are of two kinds—clear and reticulate glands.

The number for November 1892 contains:—On the development of the optic nerve of vertebrates, and the choroidal fissure of embryonic life, by Richard Assheton, M.A. (Plates xi. and xii.). That the optic nerve is formed by the differentiation of the cells of the optic stalk into nerve fibres, which consequently lose connection with the inner wall of the optic cup, and piercing the outer wall, make connection with the outer face thereof, is held to be probable by such writers as Balfour, Foster, Marshall, Haddon, and others, whilst the opinion that it is formed by the growth of nerve fibres either from the retina (outer wall of the optic cup) or from the brain, along the optic stalk, but outside it and unconnected with it, is or has been held by His, Müller, Kolliker, Hertwig, Orr, and has been recently supported by Keibel, Froriep, and Cajal. Schäfer seems to be uncertain which view to take. As the result of the author's investigations in the frog and chick, he concludes that the optic stalk takes no part in the formation of the nervous parts of the organ of sight. The optic nerve is developed independently of the optic stalk, and at first entirely outside it. The great majority of the fibres forming the optic nerve arise as outgrowths from nerve cells in the retina.—On the larva of *Asterias vulgaris*, by George W. Field, M.A. (Plates xiii. to xv.).—On the development of the genital organs, ovoid gland, axial and aboral sinuses in *Amphiura squamata*; together with some remarks on Ludwig's hæmal system in this ophiurid, by E. W. MacBride, B.Sc. (Plates xvi. to xviii.). Concludes that echinoderms agree with other cœlomata in the origin of their genital cells these latter have at first an unsymmetrical position in echinoderms, and afterwards take on a radially symmetrical disposition in correspondence with the secondarily acquired radial form of the body. The origin of these cells adjacent to the stone canal suggests a comparison of the origin of the genital cells near the nephridia in many annelids, but the homology of the stone canal with a nephridium has yet to be proved.—On a new genus and species of aquatic Oligochæta belonging to the family Rhinodrilidæ, found in England by W. B. Benham, D.Sc. (Plates xix. and xx.). This new worm receives the name of *Sparganophilus tamesis*; it was found in some numbers in the mud of the Thames, adhering to the roots of *Sparganium ramosum*, near Goring; the cocoon is drawn out to a point at one end, while in the other it shows a narrow frayed end. As the home of the Rhinodrilidæ is America, the author suggests that the cocoons of this worm may have been introduced into the Thames amongst the roots of water plants, or attached to timber from the United States.

American Meteorological Journal, December.—Atmospheric electricity, earth currents, and terrestrial magnetism, by Prof. C. Abbe. The author has collected from various telegraph companies particulars about electrical storms, which illustrate the magnitude of the disturbances that frequently occur. The present electrical and magnetic observatories, which usually observe only some part of the whole series of phenomena, need to be supplemented by completely equipped establishments recording continuously the north-south, the east-west, and the zenithal-antipodal differences of potential. The ordinary records of atmospheric electricity give merely the difference of potential of the earth and a point in the atmosphere defined as the end of the water-dropping collector.—Notes on the use of automatic rain gauges, by J. E. Codman. Observations were made continuously for three years with the object of showing what difference the size of the gauges would make in the amount of rainfall collected. The largest gauge had a diameter of over 22 inches, and the smallest 2 inches. The results show that the size of the gauge made no practical difference. He also gives the results of rainfall collected in gauges erected at various heights on a mast. The result showed that a gauge at an elevation of 50 feet or less above the surface of the ground will collect the same amount as one on the ground, provided both are situated in a position not affected by counter-currents of air. This result agrees with that found by Prof. Hellmann in his experiments at Berlin.—Sunshine recorders, by Prof. C. F. Marvin. Thus far two methods only have been in general use, (1) the focussing of the rays of the sun by means of a glass sphere and obtaining a burn on the surface of a card, and (2) the photographic method, producing a trace on sensitized paper. The first method records only bright sunshine, while the latter method is more sensitive and records fainter sunshine. Prof. Marvin has improved a method first developed by D. T. Maring of the Weather Bureau, consisting in principle of a Leslie differential air thermometer, mercury being used to separate the air in the two bulbs. When properly adjusted and exposed to sunshine the lower blackened bulb becomes heated and causes the column to rise above a platinum point and close an electric circuit. The instrument, of which a drawing is given, is said to respond promptly to sunshine and shadow. The other articles are:—Late investigation of thunderstorms in Wisconsin, by W. L. Moore.—Observations on the aurora of July 16, by T. W. Harris, and Temperature sequences, by Prof. H. A. Hazen.

THE articles in the *Journal of Botany* for November and December are mostly of interest to students of British botany. Mr. F. J. Hanbury adds two more to his new species of *Hieracium*, *H. britannicum* and *H. caniceps*; Mr. Bagnall describes a new species of bramble, *Rubus mercicus* from the Midland counties; and Mr. W. H. Pearson a new British liverwort, *Scapania aspera*. Mr. G. F. Scott Elliot contributes some useful hints on botanical collecting in the tropics.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 8, 1892.—"On the Photographic Spectra of some of the Brighter Stars." By J. Norman Lockyer, F.R.S.

The present communication consists of a discussion of 443 photographs of the spectra of 171 stars, which have been obtained at Kensington and Westgate-on-Sea during the last two years.

The chief instrument employed in this work has been a 6-inch refracting telescope in conjunction with—at different times—objective prisms of 7½° and 45° respectively.

By this method the time of exposure is short, and good definition, with large dispersion, is easily secured. The spectra thus obtained will bear enlargement up to thirty times without much sacrifice of definition.

The 30-inch reflector and slit-spectroscope at Westgate-on-Sea have also been used in the inquiry.

My object has not been so much to obtain photographs of the spectra of a large number of stars as to study in detail the spectra of comparatively few.

In the classifications of stars adopted by others from a consideration of the visual observations, only the broader differences in the spectra have been taken into account. Prof. Pickering has more recently employed a provisional classification in connection with the Henry Draper Memorial photographs of stellar spectra, but this chiefly relates to photographs taken with small dispersion. With larger dispersion it becomes necessary to deal with the presence or absence of individual lines.

In the first instance, the various stars of which the spectra have been photographed at Kensington have been arranged in tables, without reference to any of the existing classifications, and taking into account the finer details. The basis on which the main tabular divisions of the spectra are founded is the amount of continuous absorption at the blue end. This distinction was not possible in the case of the eye observations.

The stars included in the first table are characterized by the absence of any remarkable continuous absorption at the blue end, and by the presence in their spectra of broad lines of hydrogen. These have been further classified in four sub-divisions, depending on the presence or absence of other lines.

In the stars of the second table there is a considerable amount of continuous absorption in the ultra-violet, and the spectra beyond K are very difficult to photograph as compared with the stars of the first table. In these stars the thickness of the hydrogen lines is about the same as in the solar spectrum. These also are arranged in two sub-divisions.

In all the stars included in the third table there is a very considerable amount of continuous absorption in the violet, extending to about G, and it is a matter of great difficulty to photograph these spectra, as most of the stars of this class are below the third magnitude. The hydrogen lines are very thin. One subdivision includes the spectra which show flutings shading away towards the less refrangible end of the spectrum. The other comprises stars without flutings in their spectra. The brightest star in this table, α Orionis, is discussed in detail, the result tending to show that the temperature of the absorbing iron vapours is not much greater than that of the oxy-hydrogen flame.

The relations of the various sub-divisions to which reference has been made are then traced.

One important fact comes out very clearly, namely, that whether we take the varying thicknesses of the hydrogen lines or of the lines of other substances as the basis for the arrangement of the spectra, it is not possible to place all the stars in one line of temperature. Thus, there are stars in which the hydrogen lines are of the same average thickness, while the remaining lines are almost entirely different. These spectra cannot, therefore, be placed in juxtaposition, and it is necessary to arrange the stars in two series.

The next part of the paper consists of a discussion of the photographic results in relation to the meteoritic hypothesis. In the Bakerian Lecture for 1888, I brought together the various observations of the spectra of stars, comets, and nebulæ, and the discussion suggested the hypothesis that all celestial bodies are, or have been, swarms of meteorites, the difference between them being due to different stages of condensation. The new classification rendered necessary by this hypothesis differed from previous ones, inasmuch as the line of evolution followed, instead of locating the highest temperature at its commencement, as demanded by Laplace's hypothesis, placed it much later. Hence bodies of increasing temperature were demanded as well as bodies of decreasing temperature.

The question how far this condition is satisfied by the new facts revealed by the photographs is next discussed.

This involves the consideration of some points in connection with the hypothesis to which brief reference alone has been made in previous communications. The phenomena to be expected on the hypothesis, and the actual facts, are given side by side below :—

Nebulæ.

The bright lines seen in nebulæ should have three origins :—	
(1) The lines of those substances which occupy the interspaces between the meteorites. Chief among these, from laboratory experiments, we should expect hydrogen and gaseous compounds of carbon.	(1) Lines at wave-lengths approximately very closely to the lines of hydrogen, and to some of the carbon flutings, appear in the spectra of nebulæ.
(2) The most numerous collisions between the meteorites will be partial ones—mere grazes—sufficient only to produce comparatively slight rises of temperature.	(2) There is a fluting most probably due to magnesium at λ 500, and the longest flame lines of iron, calcium, and magnesium are seen.
(3) There will, no doubt, be a small number of end-on collisions, producing very high temperatures, and there should be evidence of some high-temperature lines.	(3) The chromospheric line D_3 and another line at λ 4471 (which is always associated with D_3 in the chromosphere) have been recorded in the spectrum of the Orion Nebula.

Bright-Line Stars.

The lines seen in the spectra of bright-line stars should, in the main, resemble those which appear in nebulæ. They will differ, however, for two reasons given in the paper.	Prof. Pickering has shown that the Draper Memorial photographs prove that bright-line stars are intimately connected with the planetary nebulæ, the lines in the spectra being almost identical.

Stars of Increasing Temperature.

Stage 1.—Immediately following the stage of condensation giving bright-line stars, the bright lines from the interspaces will be masked by corresponding dark ones, due to absorption of the same vapours surrounding the incandescent meteorites, and these lines will therefore vanish from the spectrum.	The spectra of stars given in the third table answer these requirements. They show no bright lines under normal conditions.
Owing to the interspaces being restricted, absorption phenomena will be in excess, and low-temperature metallic fluting absorption will first appear. The radiation spectrum of the interspaces will now consist chiefly of carbon.	The dark flutings in the visual spectrum agree very closely in position with the flutings seen in the flame spectra of manganese, lead, and iron. The evidence afforded by the photographs proves the actual presence of carbon radiation.
Under these conditions the amount of continuous absorption at the blue end will be at a maximum.	The photographs show a considerable amount of continuous absorption in the ultra-violet and violet.
Stage 2.—With further condensation, the radiation spectrum of the interspaces will gradually disappear, and dark lines replace the fluting absorption owing to increase of temperature, though this line absorption need not necessarily resemble that in the solar spectrum.	The spectra consist of numerous dark metallic lines, but they do not exactly resemble the solar spectrum. α Tauri and γ Cygni are types of stars at this stage.
Stage 3.—(1) The line absorption and the continuous spectrum at the blue end will diminish as the condensations are reduced in number, as only those vapours high up in the atmospheres surrounding the condensations will be competent to show absorption phenomena in consequence of the bright continuous spectrum of the still disturbed lower levels of those atmospheres.	(1) These conditions are satisfied by such stars as α Cygni, Rigel, Bellatrix, δ Orionis, and α Virginis. In these there is no continuous absorption at the blue end, the spectra consisting of simple line absorption.
(2) Lines of iron and other substances will disappear at this stage, because the bright lines from the interspaces will counteract the lines in the same positions due to absorption of surrounding vapours.	(2) In the spectrum of α Cygni, which represents the earliest example of this stage, there are a few of the longest lines of iron, but in other stars of this class the iron lines disappear.
(3) The chances of violent collisions being now enormously increased, we should expect the absorption of very high-temperature vapours. The solar chromospheric lines may be taken as examples of lines produced at such temperatures.	(3) The new lines which appear include the chromospheric line at λ 4471, and possibly a few others.

The Hottest Stars.

The order of the absorbing layers should follow the original order of the extension of the vapours round the meteorites in the first condition of the swarm, and the lines seen bright in nebulæ, whatever their origins may be, should therefore appear almost alone as dark lines.	In stars like α Andromedæ we have absorption lines agreeing in position with some of the bright lines which appear in nebulæ.

Stars of Decreasing Temperature.

Stage 1.—Owing to the diminishing depth of the absorbing atmosphere, the hydrogen lines will, on the whole, get thinner, and new lines will appear. These new lines will not necessarily be identical with those observed in the spectra of stars of increasing temperature. In the latter there will be the perpetual explosions of the meteorites affecting the atmospheres, whereas in a cooling mass of vapour we get the absorption of the highest layers of vapours. The first lines to appear, however, will be the longest low-temperature lines of the various chemical elements.	Taking Sirius as a type of stars in the first stage of decreasing temperature, it is found that its spectrum shows many of the longest lines of iron.
Stage 2.—The hydrogen lines will continue to thin out, and the spectra will show many more of the high-temperature lines of different elements. These will differ from the lines seen in stars of increasing temperature owing to the different percentage composition of the absorbing layers, so far as the known lines are concerned.	The conditions at this stage of cooling are satisfied by such stars as β Arietis and α Persei. In the spectrum of these stars nearly all the solar lines are found, in addition to fairly broad lines of hydrogen.
Stage 3.—With the further thinning out of the hydrogen lines and reduction of temperature of the atmosphere, the absorption flutings of the compounds of carbon should come in.	There is undoubted evidence of the presence of carbon absorption in the solar spectrum and the spectrum of Arcturus, the only star which has yet been investigated with special reference to this point.

The photographs, then, give us the same results as the one formerly obtained from the eye observations.

Comparison is then made between the groups in the classification first suggested by the eye observations, and the various sub-divisions in which the photographs have been arranged.

Geological Society, December 7.—W. H. Hudleston, F.R.S., President, in the chair.—The following communications were read :—Note on the Nufenen-stock (Lepontine Alps), by Prof. T. G. Bonney, F.R.S. In 1889 the author was obliged to leave some work incomplete in this rather out-of-the-way portion of the Lepontine Alps. In the summer of 1891 he returned thither in company with Mr. J Eccles, F.G.S., and the present note is supplementary to the former paper. The Nufenen-stock was traversed from north to south, and a return section made roughly along the eastern bank of the Gries Glacier. Gneiss abounds on the north side of the Nufenen Pass, followed by rauchwacké and some Jurassic rock. On the flank of the mountain are small outcrops of rauchwacké and of the so-called "Disthene-schists" (both badly exposed), followed by much Dark-mica schist, often containing black garnets. Higher up is a considerable mass of Jurassic rock with the "knots" and "prisms" which have been mistaken for garnets and staurolites, but Dark-mica schists set in again before the summit is reached. They continue down the southern flank of the peak : but rather north of the lowest part of the water-shed, between Switzerland and Italy, the "Disthene-schist" is again found, followed by a fair-sized mass of rauchwacké. The return section gave a similar association in reverse order ; and both confirmed the conclusions expressed by the author in 1890 as to the absence of garnets and staurolites from Jurassic rocks (with belemnites, &c.), and the great break between these or the underlying rauchwacké (where it occurs) and the crystalline schists, in which garnets often abound, of the Lepontine Alps The crystalline schists and the Mesozoic rocks are thrown into a series of very sharp folds, which, locally, presents at first sight the appearance of interstratification.—On some schistose "greenstones" and allied hornblendic schists from the Pennine Alps, as illustrative of the effects of pressure-metamorphism, by Prof. T. G. Bonney. The author describes the results of study in the field, and with the microscope, of (*a*) some thin dykes in the calc-schist group, much modified by pressure ; (*b*) some larger masses of green schist which appear to be closely associated with the dykes ; (*c*) some other pressure-modified greenstone dykes of greater thickness than the first. The specimens were obtained, for the most part, either near Saas Fee or in the Binnenthal. These results, in his opinion, justified the following conclusions :—(1) That basic intrusive rocks, presumably once dolerites or basalts, can be converted into foliated, possibly even slightly banded, schists, in which no recognizable trace of the original structure remains. (2) That in an early (possibly the first) stage of the process, the primary constituents of the rock-mass are crushed or sheared, and thus their fragments frequently assume a somewhat "streaky" order ; that is to say, the rock passes more or less into the "mylonitic" condition. (3) That next (probably owing to the action of water under great pressure) certain of the constituents are decomposed or dissolved. (4) That, in consequence of this, when the pressure is sufficiently diminished, a new group of minerals is formed (though in some cases original fragments may serve as nuclei) (5) That of the more important constituents hornblende is the first to form, closely followed, if not accompanied, by epidote ; next comes biotite (the growth of which often suggests that by this time the pressure is ceasing to be definite in direction) ; and, lastly, a water-clear mineral, probably a felspar, perhaps sometimes quartz. (6) That in all these cases the hornblende occurs either in very elongated prisms or in actual needles. The author brings forward a number of other instances to show that this form of hornblende may be regarded as indicative of dynamometamorphism ; so that rocks where that mineral is more granular in shape (cases where actinolite or tremolite appears as a mere fringe being excepted) have not been subjected to this process.—On a secondary development of biotite and of hornblende in crystalline schists from the Binnenthal, by Prof. T. G. Bonney. Both the rocks described in this communication come from the Binnenthal, and were obtained by Mr. J. Eccles, F.G.S., in the summer of 1891. They belong to the Dark-mica schists described by the author in former papers, and have been greatly affected by pressure. In each a mineral above the usual size has been subsequently developed. In the rock from near Binn this mineral is a biotite : the dimensions of one crystal, irregular in outline, and having its basal cleavage roughly perpendicular to the lines indicative of pressure, are about ·175″ × ·03″. The other mineral, from the peak of the Hohsandhorn, is a rather irregularly-formed hornblende, the crystals (which lie in various directions) being sometimes more than half an inch long. The exterior often is closely associated with little flakes of biotite. The author discusses the bearing of this fact, and the circumstances which may have favoured the formation of minerals, so far as his experience goes, of an exceptional size. Some remarks also are made on relation of these structures developed in the Alpine schists to the various movements by which those rocks have been affected, and on the general question of pressure as an agent of metamorphism. The reading of these papers was followed by a discussion, in which the President, Mr. Eccles, the Rev. E. Hill, Mr. Rutley, Mr. Teall, and the author, took part.—Geological notes on the Bridgewater District in Eastern Ontario, by J. H. Collins.

PARIS.

Academy of Sciences, January 2.—M. d'Abbadie in the chair.—M. Lœwy was elected Vice-President for 1893. MM. Fizeau and Fremy were elected into the central committee of administration. The President gave a list of the members, associates, and correspondents deceased and elected during 1892. The new members were MM. Appell, Perrier, Guyon, and Brouardel. Foreign associates, MM. von Helmholtz, and van Beneden. Correspondents, MM. Sophus Lie, Considère, Amsler, Auwers, Rayet, Perrotin, de Tillo, and Manen.—Observations of Brooks's comet (November 19, 1892) made with the *equatorial coudé* of the Lyon Observatory, by M. G. Le Cadet.—On a new method of approximation, by M. E. Jablonski.—On the movements of systems whose trajectories admit of an infinitesimal transformation, by M. Paul Painlevé.—On the general form of vibratory motion in an isotropic medium, by M. E. Mercadier.—On thermo-electric phenomena between two electrolytes, by M. Henri Bagard. The thermo-electric force between two portions of the same electrolyte in different stages of dilution was determined by experiments performed at the physical laboratory of the Faculty of Sciences at Nancy. The diaphragm employed consisted of goldbeater's skin, which has the advantage of closely adhering to the glass. The results are given in the case of zinc sulphate. With a 5 per cent. and a 45 per cent. solution the difference of potential ranged from 78 at 17·9° to 155 at 73·5°, the unit being 1/10000th of the E.M.F. of a Daniell cell. The law of intermediate bodies was strictly fulfilled, as shown by opposing a couple of 5 and 25 per cent. in series with another of 25 and 45 per cent. to a third of 5 and 45 per cent., when no deflection of the electrometer was observed between 0° and 73·3°.—On the age of the most ancient eruptions of Etna, by M. Wallerant. The first eruptions of Etna have been variously estimated to have occurred in the later quaternary or in the upper pliocene periods. These conclusions were based on the study of the prismatic basalt laid bare by the sea round the foot of the cone. The pliocene deposits found in conjunction with part of the basalt appear from palæontological evidence to be contemporaneous with the sub-Appenine blue marls, which belong to the lower pliocene. In the Cyclopean Isles the basalt is covered with a layer of clay, which is also found interpenetrated by the basalt. The identity of age of the two formations is evidenced by lenticular patches of sand interstratified in the clay, whose particles consist of fragments of pyroxene, peridote, and triclinic felspar, proving that when the sub-Apennine marls were being deposited Etna was the scene of eruptions accompanied by the emission of ashes.

HEREDITY.

Das Keimplasma. Eine Theorie der Vererbung. By August Weismann. Professor in Freiburg i. B. (Jena: Gustav Fischer, 1892.)

IN the substantial volume whose title stands at the head of this article Prof. Weismann has gathered together the results of the essays and researches which he has given to the world during the last eleven years, and he now presents us with a theory of heredity, for which his previous writings have been but preparatory.

Those who have followed the German philosopher since the appearance of "Die Dauer des Lebens" in 1882 have traversed a wide territory. They have seen many theories and hypotheses come into view and attain a certain degree of definiteness. Some of these are now lost to sight, others have changed their outline and altered the relative proportion of their parts, but, whatever was the standpoint, the central feature of Prof. Weismann's theory of heredity—the continuity of the germ-plasma—remained unchanged.

The work before us consists of an introduction, partly historical, and of four books, in which the theory and its application to various biological problems are set forth in the fullest possible manner, and in language for the most part free of technical phrases, so that a non-scientific reader can easily follow the argument. At the close of the volume are a summary of the four books and an index. The latter is a novelty in a German book of this kind, for which we cannot be too grateful to its compiler, Fräulein Diestel.

The title of the work strikes the key-note of Prof. Weismann's theory. Heredity, according to his view, is brought about by the transference from one generation to another of a substance with a definite and very complex constitution, the germ-plasma. This substance is the material basis of heredity; and it is supposed that a part of it in each reproductive cell is not used up in the construction of the offspring, but is transmitted unchanged to form part of the reproductive cells of the following generation. As the author points out, his theory might be termed "Blastogenesis," or the origin from the germ-plasma, as opposed to Darwin's Pangenesis, or the origin from all parts.

This germ-plasma is necessarily a most complicated substance; it cannot arise anew, but can grow and increase. Its ultimate constituents, according to the latest view of the Freiburg professor, are certain units termed biophores, which possess the properties of assimilation, growth, and multiplication by means of fission. So long as the organic world consisted of biophores living either singly or united in colonies, heredity and multiplication with subsequent growth were one, since each division resulted in two similar halves, which by growth gave rise to organisms exactly like the parent.

But, when the principle of the division of labour made itself felt, the biophores became differentiated, and simple division no longer sufficed to give rise to two similar organisms, each exactly like their parent. A special mechanism was needed to bring about heredity, and according to our author this was found in the nucleus. This differentiated part of the cell was originally a collection of reserve biophores. After the division of the nucleus the biophores in each half multiplied, and so replaced those which had separated from them, and thus rendered possible the completion of the new organism. The structure of the nucleus became still more complicated when amphimixis, the mingling of the hereditary substance of two individuals, made its appearance. Amongst multicellular organisms, with their endless variety of cells, the same mechanism exists, but in a still more complicated form. Sexual reproduction has arisen; that is, the "Anlagen" for the whole organism are collected into a single reproductive cell, two such cells come together, and the resulting fertilized egg cell contains the hereditary substance of two individuals.

According to Prof. Weismann's present view, this hereditary substance or germ-plasma consists ultimately of biophores. These units are built up in a definite order and arrangement into units of the second degree, which are termed "cell determinants," or simply "determinants." Every cell of a multicellular organism is dominated in its histological character, and in the rhythm and nature of its division by one of the determinants. Each cell has not, however, a corresponding determinant in the germ-plasma, but cells of the same sort, as, for instance, blood corpuscles, may be represented in the hereditary substance by the same determinant. In the germ-plasma of any species there must be as many determinants as there are variable cells or cell groups in the organism. The determinants are arranged in a definite order in units of the third degree termed "ids."

These ids, which will be familiar to readers of Prof. Weismann's latest essay, that on Amphimixis, are again built up into idants, and these last probably correspond with the chromatosomes, or nuclear rods of the nucleus. Thus the germ-plasma consists of idants; the idants are composed of ids; the ids are built up in a definite manner of determinants; and the determinants are formed of the final units, the biophores.

It is assumed that the biophores can pass out of the nucleus and divide and multiply in the surrounding cell protoplasm. Amphimixis brings about the mingling of a certain number of biophores from one parent with a similar number from the other, and the organism whose body is dominated by this mixed assemblage of biophores partakes of the nature of both parents.

In the reproductive cells of the higher plants and animals the nucleus must contain not only those determinants which dominate the structure, rate of division, &c., &c., of the cell itself, but also those which will dominate the various cells and systems of cells which will eventually arise from the reproductive cell; and furthermore these must be definitely arranged in a given order, so that they may not be all called into activity at once, but may become functional successively, in accord with the origin of the cells they control.

It is not possible within the limits of a short article to describe the many ingenious applications of his theory, by means of which Prof. Weismann attempts to explain such phenomena as the Regeneration of lost parts, Reversion, Budding, Alternation of Generations, &c.: all these are brought into line, and are shown to be capable of an explanation in the theory of germ plasma. Dimorphism and seasonal dimorphism are explained by the assumed existence of double determinants, one corresponding with each form, and remaining inactive during the life-time of the organism controlled by the other.

Such changes as affect the cell body cannot be transmitted according to this view, since alterations in the cell have no effect upon the biophore which in the next generation will dominate the corresponding cell of the offspring. But, since variation must be ultimately dependent on external circumstances, influences such as climate, change of food, &c., are considered to have in the course of time some effect upon the determinants, and a corresponding change in the organism results. In this lies one of the chief differences between the germ-plasma theory of Prof. Weismann and the Pangenesis of Darwin. They both give a possible explanation of heredity; but in the latter case the gemmules, coming from every cell of the body, afford an explanation of the transmission of acquired somatic changes; in the former case the biophores, arising only from other biophores, would be uninfluenced by any such change. A. E. S.

THE BASIS OF ALGEBRA.

The Algebra of Co-planar Vectors and Trigonometry. By R. Baldwin Hayward, M.A., F.R.S., Senior Mathematical Master in Harrow School, formerly Fellow of St. John's College, Cambridge. (London: Macmillan & Co., 1892.)

THIS work is constructed on the methods of the school of mathematicians who derived their inspiration from the teaching of De Morgan, a school which is represented by many of the most influential of our recent writers on mathematical subjects. It is intended to occupy the place of the "Trigonometry and Double Algebra," published in 1849 and now a long time out of print, at the same time incorporating such improvements in elementary treatment as have been evolved out of half a century's discussion of the foundations of Algebra. Those who are acquainted with Mr. Hayward's other writings, such as his "Elements of Solid Geometry," will expect a fresh and interesting treatment of his subject; and they will not be disappointed. On turning over the pages we constantly come across elegant touches and happy turns of expression, and historical appreciations—the stuff which constitutes the basis of literary excellence in mathematical writings.

The treatise is primarily concerned with the logical exposition and illustration of the principles on which Algebraic Analysis, including Analytical Trigonometry, is founded. The utility of this subject in its practical applications renders it a necessary part of even an elementary course of reading; while a very refined treatment of it may lead so far into the notions of the Theory of Functions and algebraic continuity in general, as to somewhat overlay the really simple matters with which it is concerned. In this country the tendency in elementary books has, until recently, been rather to take the fundamental formulæ on credit, and to make the subject consist of the development of their analytical and practical consequences. The philosophical principles which bind them into an organic whole have retained so much the aspect of *à posteriori* developments, that there is some temptation to proceed in the view that Mathematical Analysis is an inductive science like Natural Philosophy; that it is one part of the science to invent and verify the formulæ, while the logical calculus which gives them precision and limitation is quite another department. The great majority of readers of the elements of Algebra have no time for an exhaustive discussion of the nature of continuous quantity and all the types of singularity to which it is liable; while on the other hand complete neglect of the logical basis of Analysis deprives it both of a main source of its interest, and of a large part of its value as an intellectual training. Hence arises the importance, even in presence of the complete theory with which a specialist must be acquainted, of the simplification and improvement of methods of exact treatment within the domain of elementary ideas.

The author's method starts off from an *à priori* discussion of the Algebra of Co-planar Vectors, which leads him to the two modes of specification of a vector, as a power of the fundamental vector, and as a sum of components. The identification of these two expressions leads to the analytical definitions of the *sine* and *cosine*, and by way of certain theorems in algebraic limits [whose explicit enunciation is by the way not essential] to the orderly development of the subject. The theorems concerning series which involve the complex variable are strikingly illustrated by corresponding vector chains, and geometrical interpretations are throughout very copious. The treatment is here so full and many-sided, that it would form an interesting occupation for the reader to take up the other aspect of the matter, and try to pick out the simplest and briefest analytical foundation on which the formulæ required for practical applications may be built.

The remarkable formula of p. 115, $(4{\cdot}810475\ldots)^{\iota} = \iota$, if removed from the context in which it is set, might be propounded as a puzzle in interpretation. The author introduces us straight off to an expression with a complex index, and proceeds to ascertain whether any meaning can be assigned to it, which will allow the inclusion of such expressions in the algebraic calculus. The geometrical method gives him very neatly and definitely an expression for the values of A^B, where A and B are both complex, by means of the vector ribs of a fan of equiangular spiral form. But when the conception of logometers (analytical logarithms) to a vector base comes up for interpretation, the answer proves to be some one of an infinito-infinite series of vectors related to one another in a manner so complicated as to elude definite grasp; and we have arrived at a case in which the inclusion of the function in our calculus would, in the absence of special machinery of representation like a Riemann's surface, be best avoided.

The origin of all difficulty in the treatment of complex algebra lies in fact in the multiplicity of values of the functions with which it deals. If each function can be defined as spread out in a multiple sheet so as to be single-valued at each point on each leaf of the sheet, a great part of the trouble disappears. We can then if we please make explicit use of the Principle of the Permanence of Equivalent Forms, which, after having been expounded at length and defended by Peacock (appendix to "Algebra"), has been summarily rejected as misleading and unmeaning by many recent authors. To the formal reintroduction of this principle Mr. Hayward's language exhibits a tendency to return. Outside the domain of elementary Algebra, its strict employment in the prolongation of an analytical function into a new region is indeed of common occurrence in Analysis; while its tentative application in unrestricted form, as an instrument of suggestion and discovery in the Theory of Operations, is fundamental. To the effort to widen the limits of interpretation in connexion with it, has been due most of the advances in Analysis.

It is a fundamental question in mathematical logic how far, after having carried the stream of our analysis through regions of uninterpreted symbols, and having at length arrived at a stage in which these symbols have disappeared, we are entitled to claim this procedure to be demonstrative. It is of course of the very essence of Algebra that the intermediate steps of its analysis remain uninterpreted; though in the Algebra of real quantities we have a tacit assurance that an interpretation can be supplied if necessary. Why then was there an objection to a similar procedure in the Algebra of complex quantities; and what is the source of the timidity and doubt which characterized the use of complex analysis before its geometrical interpretation was developed? Simply that complex quantities turned out to be multiple-valued, and that the selection of the proper value under given circumstances had to be settled by tracing the continuity of the quantities in a way that was to the mind practically impossible until a visual geometric representation was discovered. The Argand diagram is not essential to the logic of the matter; it rather makes Analysis possible by bringing its scope within our grasp. It simply forms a more extensive and systematic example of the method which has been in use since the time of Descartes for studying functions and approximating to their roots, by aid of their graphical representation.

The Principle of Permanence of Equivalent Forms thus lies at the very root of Algebra, but it is rendered ineffective by indeterminateness of interpretation. Its strict use, when most needed, is subject also to another hitch. It requires that the forms be expressed in exact terms; an infinite series must be expressed in the sum of n terms together with a residue R. These residues must be retained throughout the analysis until we arrive at a point where interpretation comes in; and it must then be settled how far they can be neglected in the circumstances of the actual interpretation. In the language of Mr. Hayward, it cannot be asserted about series that are not absolutely convergent, that the fundamental laws of Algebra hold without limitation.

It is perhaps a question how far the idea, thus restricted and safeguarded, is worth being expressly retained as a working principle of ordinary Algebra. In subjects like the Calculus of Operations and Finite Differences, which are still in an unsytematized stage, it cannot be dispensed with; and the extent to which its use is boldly pushed, by De Morgan and Boole, even to the discussion in an operational manner of divergent series without their residues, contrasts with the more exact processes of recent Analysis. How far this boldness arises from the profound logical studies of these writers, and their appreciation of the imperfect character of inference at the best, may be a subject open to discussion.

In connexion with the doctrine of convergence of series, the author gives a very clear account, from Sir G. Stokes, of how it is that, on approaching certain critical points, the convergence may gradually fall off and finally disappear. The illustrations employed are algebraic series of an exceptional character; and the whole circumstances may possibly suggest to the uninitiated that it is a phenomenon of exceptional rarity. The most natural context is, of course, in connexion with the wonderful and far-reaching theory initiated by Fourier, by means of which functions arbitrarily discontinuous are expressed by seemingly continuous series. In that connexion, the necessity of explanation is so obvious that it is interesting to examine the previous attempts at elucidation. Thus De Morgan, in 1839, is able to conclude ("Diff. and Int. Calc.," pp. 233, 239) that such discontinuity cannot occur in series proceeding by powers of a real variable; that in other cases it occurs only through the series becoming divergent at the point of discontinuity. It is, however, an important question how far it would be allowable to avoid burdening an elementary exposition by complete precautions against the existence of anomalies like this, which would hardly have originally occurred to any one in that early stage.

The book ends with a wider survey, including a clear and interesting account of Cauchy's theory of the radical points of a rational function. The graphs of the cubic $z^3 + az$, which are given as an illustration, would also form excellent and rapid examples of the Rankine-Maxwell method of graphical addition, applied to the separate graphs of z^3 and az.

FOSSIL PLANTS AS TESTS OF CLIMATE.

Fossil Plants as Tests of Climate, being the Sedgwick Prize Essay for the Year 1892. By A. C. Seward, M.A., F.G.S., Lecturer in Botany in the University of Cambridge. (London: C. J. Clay and Sons, Cambridge University Press, 1892.)

THIS admirable essay is really a digest of the opinions of the principal writers on fossil plants, so far as they throw light on geological climates, and a critical *résumé* of the subject up to date. It should be read by all who prefer to deduce the relative temperatures of various latitudes in the past from such solid data as assemblages of ferns, cycads, and conifers, the ancestors of living genera and species, rather than from utterly extinct belemnites, ammonites, and saurians, of whose habits little can ever be known, and which might have drifted far out of their temperature zones by warm and cold sea-currents.

Perhaps if any criticism can be made, it is that too little has been said by the author as to what is known of the Mesozoic floras, which, if scanty, are extremely interesting. In fact only the widely-separated Palæozoic and Cenozoic floras are fully dealt with. Owing to the magnitude, difficulty, and freshness of the problems presented by the former, they have received the larger share of attention and have ever attracted some of the most acute and philosophic of scientific workers. But while the researches of such investigators as Williamson and Renault into the actual structures and affinities of the carboniferous plants have been rewarded with the most brilliant successes, attempts to speculate and theorize have only been productive of barren controversy. All inferences as to the temperatures in which they flourished have merely been inductions from unknown data: their affinities with existing plants are so remote that they can tell us of little beyond moist climates and spongy, marshy soils, liable to inundation, with possibly an atmosphere more highly charged with carbonic acid than at present. But that neither the flora nor identical conditions were uniformly present over the whole land during the deposition of the carboniferous, becomes every year more apparent; and perhaps few would now maintain that fossil floras met with in widely-different latitudes must necessarily be contemporary because similar, or reject as impossible the correlation of the Glossopteris floras of the southern hemisphere simply because they are so dissimilar.

Tertiary floras, however, have to be approached from almost totally different standpoints, for here minute investigations into vegetable structure can only exceptionally lead to important results. On the other hand it may be possible to predicate the climate that any group among them would have required, with almost perfect accuracy. Allowing that even most closely-allied species may have had different habits, enough remain that are practically identical with living species. These not only prove to us that in every land in our hemisphere the temperatures remained warmer throughout the Tertiary period than at present, but also that the temperatures were far from equable during Eocene time. Thus it is impossible to hesitate as to the evidence of the flora in the lower stages of our Eocene, which exhibits an abundance of planes, poplars, and alders and an absence of all approach to sub-tropical essences; nor as to that of the London Clay, with its tropical nipas, sabals, and a host of others almost indistinguishable from species existing at the present day. There is scarcely need of the corroborative evidence of the Mollusca as to cooler seas in the Thanets, nor of tropical conditions in the large turtles, crocodiles, snakes, and nautili of Sheppey. In fact, the temperature of the spots occupied by Reading, Bournemouth, or Mull at a particular stage of the Eocene could be predicated from the fossil floras almost as accurately as from living plants. If the same cannot be said of the Arctic regions it is simply that the specimens brought home are, perhaps from the exigences of travel and inexperience of the collectors, for the most part so imperfectly preserved and fragmentary, that few of the determinations can carry the smallest weight. It may suit quidnuncs to accept indeterminable fragments as evidence of the growth of palms and cycads in the Greenland Eocene—it is time the Miocene age of these beds was relegated to the limbo of Coal-measure palms and yuccas—and to become excited over the presence of a sub-tropical flora within the Arctic circle; but as a fact it is doubtful whether anything has been discovered there which might not have grown in our own temperature, if slightly modified, a state of things which it is conceivable the damming back of the Arctic seas by the land connection which then existed between Europe and America, aided by an active Gulf Stream, might have brought about. When we come to the Miocene, worked out as that of Switzerland was by Heer, or still more the Quaternary, with such data as those laboriously amassed by Clement Reid, the inferences as to climate are still more irresistible.

As to evidence of the age of rocks, plants are less trustworthy, because they have neither been so perfectly studied nor are their zones as yet at all properly defined. All we can say is that certain assemblages are found in association at the beginning of the Tertiary, and that changing temperatures have since compelled them not to disperse, but to migrate far and wide. Fewer probably of the species are extinct than is generally supposed, and the primitive associations have held together perhaps to the present day, with many gaps from extinction and desertion and a large infusion of recruits through the ordinary causes of evolution, stimulated by the increase in browsing mammalia. Whether, on the other hand, the marine deposit zones are really entitled to the weight attached to them as evidences of age, except locally, is not so clear. They are usually the littoral deposits of a limited area, where some changes of level or current have apparently suddenly driven out the fauna and introduced new colonies more adapted to the changed conditions. If we could follow the subsequent wanderings of these assemblages under the sea our faith in their sudden extinction and consequently in their chronological value might be greatly modified. At all events, many of the less conspicuous groups of mollusca, when critically examined, prove to have surprisingly near relatives in distant seas at much later periods, and even at the present day.

J. STARKIE GARDNER.

OUR BOOK SHELF.

Pioneers of Science. By Oliver Lodge, F.R.S. (London and New York: Macmillan and Co., 1893.)

THIS book consists of eighteen lectures on the history and progress of astronomy, which were delivered by Dr. Lodge in 1887. "The lectures having been found interesting," he thought it "*natural* to write them out in full and publish," and, although this can scarcely be considered a sufficient excuse, the intrinsic merits of the work are abundant justification for its existence. In Part I., "From Dusk to Daylight," the progress of astronomy from Copernicus to Newton is traced in a series of vivid pictures of Copernicus, Tycho Brahe, Kepler, Galileo, Descartes, and Newton; while Part II., "A Couple of Centuries' Progress," brings the history of gravitational astronomy from Newton down to the present time. In these latter lectures Roemer and Bradley are associated with the velocity of light and aberration; Legrange and Laplace with the solar system and the nebular hypothesis; Herschel with the motion of "fixed" stars; Bessel with the distances of stars; Adams and Leverrier with the discovery of Neptune; and Lord Kelvin and George H. Darwin with tides. Dr. Lodge has been able, by judiciously combining clear statements of scientific facts and laws with interesting personal details, to give his lectures all the charm of a romance. The book is an admirable introduction to the study of astronomy, and no better gift for a beginner could well be chosen; while to those to whom many of its details are already familiar, the picturesque clearness with which they are presented will make their knowledge more real and more complete. The standard of excellence maintained in the lectures makes distinction difficult and invidious, or we would distinguish the lectures on Newton and those on tides as models of what such popular scientific expositions should be. The book is copiously, and, on the whole, well illustrated, but some of the illustrations—notably those of clusters and nebulæ—are very familiar and somewhat out of date. A curious mistake occurs on page 291, where a well-known drawing of a comet appears as an "old drawing of the Andromeda nebula." The illustration on page 326, showing the paths of Uranus and Neptune and their relative positions from 1781 to 1840, and professing "to illustrate the *direction* of their *mutual* perturbing forces," is partly misleading; but in introducing this Dr. Lodge has erred in good company, for the diagram, originally due to Dr. Houghton, appears in many of our recent astronomical text-books. A. T.

Electric Lighting and Power Distribution. Part I. By W. Perren Maycock, M.I.E.E. (London: Whittaker and Co., 1892.)

THIS cheap and useful little text-book has been written for the author's junior students, as he is of opinion that no trustworthy elementary work on the subject is to be obtained. The scope of the work has been limited to the syllabus of the ordinary grade examination of the City and Guilds of London Institute. We find, however, much information on subjects not usually found in other manuals. The book is freely illustrated, and the descriptions are clear.

It is very important for the junior student to understand clearly what is meant by a line of force, and to grasp the fact that lines of force are only *assumed* to exist, because, by such an assumption it is possible to explain many, otherwise inexplicable, phenomena. On page 47 we find the following statement:—"The power which any magnet possesses, of picking up pieces of iron, and of acting upon another magnet, depends upon the existence of lines of magnetic force." This quotation is vague; a junior student might easily imagine that the lines of force really existed, whereas they are purely assumptions, to elucidate the phenomena of magnetic attraction. The illustrations of simple bar magnets, solenoids, and electro-magnets, in which the lines of force are delineated, should have the assumed directions of the lines of force clearly shown by arrow-heads. This might be done with advantage in Figs. 17 to 20.

Chapter IV. deals with induction of currents, electromagnetic induction, Faraday's Law, and concludes with a clear description of magneto-motive force, magnetic resistance, magnetizing force, induction and permeability. These latter are very difficult for a junior student to understand thoroughly, and the author should have devoted more space to the discussion of these important points in dynamo construction. One particularly good feature in this text-book is the large number of questions arranged at the end of each chapter. These are well suited to test the knowledge of a student. Chapter V. deals generally with electrical testing, measuring instruments used in installations, and meters for measuring the current, such as Teague's, Elihu Thomson's, and the Wright-Ferrauti. Chapter VI. concludes the book, describing the principle of the dynamo, different types of machines, and the construction of the various parts.

Taken as a whole this book attempts too much. The matter described has suffered considerably by condensation, a serious thing where junior students are concerned. Most of the illustrations are good; some are indistinct, and Fig. 98 is decidedly wrong, showing the brushes set for one direction of rotation, and the arrow indicating the reverse.

On the other hand the sequence of matter is good, and a student should learn much from the work. The author takes great pains to describe clearly the many units involved, particularly the applications of Ohm's law. The book would last much longer in the hands of the average student if the present paper binding were replaced by something stronger.

The Naturalist on the River Amazons. By Henry Walter Bates, F.R.S. With a memoir of the author by Edward Clodd. Reprint of the Unabridged Edition. With Map and Numerous Illustrations. (London: John Murray, 1892.)

THIS work is so well known, and has long held so high a place among scientific books of travel, that it is unnecessary to do more than note the appearance of a new edition. It is clearly printed on good paper, and the illustrations are well reproduced. The introductory memoir by Mr. Clodd is a most welcome record of the main facts of Mr. Bates's career. The materials for this interesting sketch were enriched by letters placed at the author's disposal by Sir Joseph Hooker and Mr. Francis Darwin. An excellent portrait of Mr. Bates is included in the volume.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

A Proposed Handbook of the British Marine Fauna.

SUCH a handbook as Prof. Herdman suggests is so much wanted that many naturalists must from time to time have felt tempted to essay it. But the difficulties are very formidable. Prof. Herdman seems to contemplate the preparation of such a work mainly as a labour of compilation. But the groups where compilation would nearly suffice are just those where the handbook is least required. On the other hand, such a group as the Amphipoda, in spite of Canon Norman and Mr. Stebbing's many papers, is still in great need of revision; it was only the other day that Canon Norman opened our eyes to our rich fauna of Mysidæ, before which time no search among published records would have told us anything worth the having; we are in just the same position as to our British Cumacea, until Canon Norman again reveals the treasures of his cabinet; our Pycnogrns are almost as little known. In every one of these groups, and in many others like them, the preparation of a hand-list would need the experience of a specialist, just as much as the Tunicata would require Prof. Herdman's own special knowledge. The area to be embraced is another difficulty. Prof. Herdman proposes to take the British area as defined by "Canon Norman's" B.A. Committee in 1887, on which he himself served. But the committee's report was repudiated by Canon Norman himself, who afterwards suggested a wider "British area," whose boundaries I fancied had since been recognized as more suitable by everybody. However the British area be defined, there will long remain a difficulty in the numerous forms not yet recorded from within it, but which are likely, or certain, to turn up when sought for. Such things as the parasitic and other Crustacea described of late years by Giard and his pupils from Wimereux form a case in point. I am inclined to think that to make in the first instance a hand-list of the whole fauna of the North Atlantic basin would be not a bit more difficult, but in some respects easier, than to restrict the list to the British area alone. That it would be incomparably more useful is certain. It would make a book not more than three times (perhaps little more than twice) as big as Carus's "Fauna Mediterranea." And it would be a very important step towards that new *systema naturæ* of which the Germans are already beginning to talk, and which it is high time were begun.

But Prof. Herdman both asks discussion of his plan, and also invites criticism on his execution of it. Take his very first illustrative genus, which he tabulates as follows:—

ANTENNULARIA.—Stems simple or branched; pinnæ verticillate; nematophores along the stems; gonothecæ axillary, unilateral.

A. antennina, L., stems clustered, usually simple; hydrothecæ separated by 2 joints. 6 to 9 in. high. Gen. distr. deep w.

A. ramosa, Lamk., stems single, usually branched; hydrothecæ separated by 1 joint only. 6 to 9 in. high. Gen. distr. deep w.

Now there are *no* nematophores along the stem, but only on the pinnæ; *A. ramosa* may sometimes grow up unbranched, but I for one never saw it so, and *A. antennina* is always simple, save by the rarest individual abnormality; the dimensions are quite inaccurate, for we have *A. antennina* here of all sizes up to 24 inches high. The distribution given is too vague. In the report of the B.A. Committee, which Prof. Herdman goes by, deep water is defined as that below 100 fathoms; but these two are not deep-water species, either in that or any other common use of the phrase. The authorities are very loosely given. *A. antennina*, L., should be (L.), and if the bracketed authority, *i.e.* the original user of the specific name, is to be the one quoted, then for *A. ramosa*, I think Lamk. should give place to (Lamx.). And why is the authority for the genus left out altogether?

Moreover, even if these definitions were verbally accurate so far as they go, they would only suffice to exclude one another, with no reference to other non-British species. They are rather definitions of groups of species or sub-genera, than of these two particular forms. It would not matter very much, perhaps, in this case, where other species are not likely to turn up upon our coasts; but such definitions, drawn with reference only to known British forms, would soon lead to hopeless confusion in the case of less-known groups. D'ARCY W. THOMPSON.

Dundee, January 11.

On an Abnormality in the Veins of the Rabbit.

AMONGST a number of rabbits dissected in my laboratory last term, one specimen exhibited a peculiarity in the venous system which is especially interesting in connection with Hochstetter's and Macalister's accounts of the development of the veins. Unfortunately the specimen had been too far dissected before the abnormality was noticed to follow out every detail.

The blood from the hinder extremities, urinogenital organs, and abdominal walls, passed into a large vessel having the position and relations of a postcaval posteriorly. Instead, however, of passing through the dorsal border of the liver to penetrate the diaphragm, it was seen at the anterior part of the abdomen to correspond to the azygos, receiving the superior intercostal veins, and opening into the right precaval. This vessel evidently, then, corresponded to the persistent right posterior cardinal. The portal system was apparently normal, and the hepatic veins opened into a postcaval, which extended through the diaphragm to the heart in the usual manner.

Thus the independently-formed section of the postcaval (*Leberabschnitt*) had taken on no connection with the part developed from the cardinals (*Urnierenabschnitt*), but had remained as a separate vein, bringing back the blood from the alimentary organs (and ? diaphragm) only.

I have not thought it necessary to do more than mention these facts, as the whole question has recently been fully discussed by Dr. A. Robinson ("Abnormalities of the Venous System and their relation to the Development of Veins," "Studies in Anatomy from the Anatomical Department of the Owens College," vol. i. p. 197, Manchester, 1891). The above case, however, supports the view that the renal veins are direct tributaries of the right cardinal, and not of the postcaval; while the reverse conclusion is derived from Dr. Robinson's observations. W. N. PARKER.

University College, Cardiff, January 14.

Difficulties of Pliocene Geology.

YOU were good enough to print a letter from me a week or two ago, in which I called attention to some of the difficulties in explaining the distribution of the so-called Pliocene beds. I should like to prosecute the subject a little further.

The geographical distribution of the mastodon is assuredly one of the greatest paradoxes in natural science.

As is well known, it occurs both in North and South America, and on both sides of the Rocky Mountains and the Andes. It has not occurred, however, so far as I know, north of the great lakes in the east, nor of Oregon in the west, nor has it ever been reported from Alaska, where mammoth remains are so abundant. I do not know any evidence that it has been found anywhere in Asia, north of the Himalayas, neither in China, nor Manchuria, nor Mongolia, nor Turkestan, nor in Siberia; nor has it occurred in European Russia, except close to the Black Sea, nor in Poland, nor in Scandinavia, nor in North Germany.

In the Old World its zone of distribution extended from India to the Pyrenees, including the Mediterranean borders, the valleys of the Danube, and the Middle Rhine, Eastern England, and perhaps Iceland, whence some teeth are said to have been sent to the royal collection at Copenhagen. This distribution of a very highly specialized beast is certainly most extraordinary. Granted that the mastodons of Western Europe and those of America are slightly different, the difference is so slight that, as Falconer says, Cuvier treated them as the same species, and they cannot have been very long isolated. Yet how are we to explain the facts, and do justice to the widespread view that the ocean areas are very old?

It seems to me as clear as anything can be that when the mastodon was distributed over Western Europe and America, there must have been a land communication between the two areas, and I cannot see how, with the facts before us, we can escape the conclusion that this connection must have been across either the Atlantic or the Pacific, not in high but in low latitudes, perhaps across both.

The mastodon is not the only animal which points the same lesson. The machairodus, a very highly specialized feline, has been found both in the Old and the New World, but did not inhabit the great palæarctic province of Europasia, east of the Rhine, nor America north of the great lakes. The American jaguar, a mere variety of the Old World leopard, is another animal with the same abnormal distribution, so are the American and the Old World tapirs.

Now this connection between the Old and the New World cannot, so far as we can judge, have been in high latitudes, for the forms in question have not occurred in high latitudes. If the connection had been across the Northern Pacific, we should have had some remains of these animals in Japan, where more than one fossil elephant has occurred; or in the Sandwich islands, which are, to all appearances, a very old land-surface.

The connection must, therefore, if it was across the Pacific, have been across its more equatorial part. It seems similarly to follow from the absence of these animals in the high latitudes of America and Europe, save the doubtful case of Iceland, that in the case of the Atlantic also the land-bridge must have been further south, and perhaps where the Atlantic islands still remain. One more inference. If there was a penannular or circular belt of land about the earth in the tropical or subtropical zone over which these beasts could travel, it would possibly account for the tertiary climate of high latitudes having been a warm one, as we know it was. A zone of land in the tropics would act as a furnace, whose heat would be widely distributed by the ocean currents in contact with it.

The views here urged, it will be said, are like those of the advocates of a Miocene Atlantis. They are in essence very different, and meant to explain a very different phenomenon, namely the aberrant and abnormal distribution of the mastodon and its companions. The mention of the Miocene Atlantis, however, suggests another and more critical difficulty in explaining the Pliocene beds, but this must be postponed to another letter. HENRY H. HOWORTH.

The Athenæum Club, January 13.

Earthquake Shocks.

A SERIES of slight earthquake shocks have lately occurred in this district, viz. January 3, 2.15 p.m. at Severn Junction (E.J.L.) January 4, 11 a.m., Itton Court, Chepstow (a heavy plant; in a greenhouse was seen to move four times by Mr. J. Curr and the Rev. N. S. Barthropp); January 5, between 2 and p.m., and again on the 6th (a little earlier), Llanthony Monastery (a rumbling noise on the Black Mountains near the monastery Mr. P. E. Hill); January 14, 6.55 p.m., a shock lasting more than a second, Bigswear House, Coleford, Mr. J. V. Newbery (Mr. Newbery has had experience of earthquakes, from a long residence in Japan). E. J. LOWE.

Shirenewton Hall, Chepstow.

The Weather of Summer.

I REGRET to find that, in making a quotation at the end of my letter last week (p. 246), I erred in supposing Mr. Symons to be the writer. I beg to apologize for the slip. A. B. M.

ON THE ORIGIN OF THE ELECTRIC NERVES IN THE TORPEDO, GYMNOTUS, MORMYRUS AND MALAPTERURUS.

THE subject of this communication may seem remote and uninteresting, but it will not be difficult to show that questions of the highest importance for physiology, anatomy, and the Darwinian theory are closely related to those touching the structure of the electric organs of certain fishes and the laws of their functions.

The fact that the body of an animal should become a complete electrical apparatus acting at the will of its owner induces us to inquire how this extraordinary result has been attained; that is, to investigate the origin of the electric organs of fishes, and the manner in which the animal throws them into action. We shall see that in pursuing both lines of enquiry we open far-reaching views into regions as yet unknown.

According to the present state of our knowledge there can be no doubt that most of the electric organs hitherto discovered are of muscular origin. It is not my intention to dwell on this transformation of muscular tissue, but it may nevertheless prove interesting to cite an example of the completeness with which such transformation can take place; I refer to the Mormyrus—the so-called pike of the Nile—a fish which has only of late been sufficiently known to possess electric power. A transverse section of the tail of any ordinary fish shows scarcely anything more than the vertebral column, muscles and their tendons, attached to the bones. On the other hand, a transverse section of the tail of Mormyrus (Fig. 1) shows no conspicuous muscles, but in place of them electric tissue filling up the entire space occupied by muscles in ordinary fishes. Of the muscular apparatus there is nothing left except the longitudinal tendons passing outside the electric organs from muscles placed anteriorly. If these tendons were cut across the Mormyrus would be unable to move its tail.

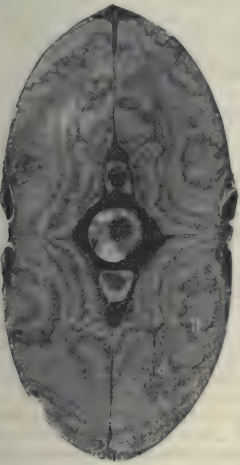

FIG. 1.—Transverse section of the tail of *Mormyrus cyprinoides*.

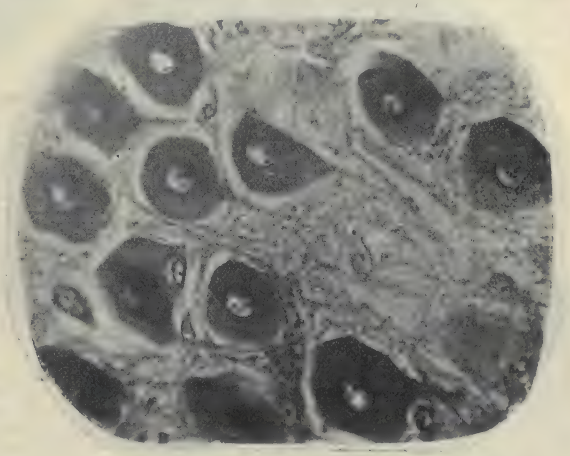

FIG. 2.—Ganglion cells from roots of electric nerves of Torpedo.

Omitting the complicated arrangement of histological elements in this modified muscular tissue in the different electrical fishes—which could not be sufficiently explained without a large number of illustrations—it may be sufficient to state that a kind of swelling loosens the molecular elements of the muscles and allows them to be settled again in a very regular but quite new form.

The well-known electric eel of America, *Gymnotus electricus*, has only the external shape of an eel, and is in reality a very short fish, carrying very powerful electric organs in a long tail springing from a very short rump. A transverse section of the tail shows that a part of the muscle is changed into electric organs, while another remains unchanged.

In the different kinds of electric skates—Torpedinidæ—the electric organs are developed from muscles, which originally belong to the branchial arches and the arch of the lower jaw.

When we look to the nerve apparatus which enables the fish to throw the electric organs into action by a voluntary impulse, we find in every case wonderfully developed ganglion cells from which the impulse is transmitted directly to the electric batteries. Such a coincidence certainly cannot be the result of mere chance. But beyond the invariable presence of large ganglion cells as the starting points of electric nerve fibres there is very little uniformity in the arrangement of these elements in the different sorts of electrical fishes; on the contrary, there are most remarkable and striking differences not only in the position but also in the number and in the appearance of these nerve centres. It is to be hoped therefore, that some important views regarding the character and functions of ganglion cells in general may be suggested by their study.

In the Torpedo the electric ganglion cells—being in vast numbers—form a bean-shaped mass in the medulla constituting the well-known electric lobe. It represents modified motor centres of the vagus nerve; anteriorly it is covered by the cerebellum, but emerging from beneath that organ, the lobe increases rapidly where the largest electric nerve leaves the medulla. Lower down its size again diminishes, where it gives rise to the fourth electric nerve and terminates quite free in a blunt point on each side. On counting the ganglion cells in a complete series of sections one finds the number to be about 54,000—a number that can be found to nearly correspond with the fibres in the electric nerves that arise from them. A transverse section of the medulla, close to the spot where the roots of the electric nerves are gathering, shows the so-called axis cylinder processes of the cells entering the roots to form the nerves. This is seen in Fig. 2—a photogram taken from nature like all the other illustrations of this paper.

Even the first and smallest of the electric nerves shows a great number of nerve fibres collected into bundles which on transverse section appear as if perforated by numerous small openings—each apparent aperture being a nerve fibre. I counted about 8039 fibres in the first electric nerve, in the second or largest about 23,770; in all four nerves about 58,318 fibres. This total exceeds that of the ganglion cells by at least 4000, but the disparity of number is probably to be accounted for by the impossibility of getting an exact total from a series of sections where the cells are very often dragged away by the knife.

The ganglion cells of the Gymnotus, or electric eel, are disposed in a different manner. Behind a short portion at the anterior end of the spinal cord where ordinary cells are found, the grey substance contains large rounded ganglion cells, the most anterior of them forming a semicircle around the central canal of the cord. Since these first cells extend in front of the most anterior electric nerves, a transverse section of this region shows no axis cylinders leaving the grey substance, all being directed downwards to the gathering place of the first electric nerve roots, and therefore must be cut off. If, however, a transverse section be made in the middle portion of the cord the whole grey matter is seen to be packed with electric cells and their axis cylinders are seen passing very straight and undivided to join the electric nerve roots at once. The other processes of the cells are so pale and fine that it is impossible to recognize them sufficiently well in a complete section. Since the electric batteries extend along both sides of the tail to its very end, the electric nerves and their ganglionic centres have a similar extension. The electric cells form a continuous column in the spinal cord, but it is very slender, therefore, notwithstanding the great longitudinal extent of the electric centre, the number of cells is not so very great. I estimated the total number of cells to be about 60,000—not many more than the estimated number in the Torpedo.

The genus Mormyrus, whose electric power was doubted until quite recently, resembles the Gymnotus in the structural arrangement of its electric apparatus. I was fortunate enough to find the ganglion cells for the electric nerves in the spinal cord, where the tail is endowed with the electric batteries, as seen in Fig. 1. The cells are very soft, and must be very carefully preserved to show all their details. Their regular undivided axis cylinders leave the cord-like motor roots, and form a sort of plexus before leaving the vertebral canal. It is to be considered as a very important fact, that broad processes of the cells regularly intercommunicate on so large a scale that their union into a complete system for simultaneous action cannot be doubted.

Fig. 3 shows such cells in the grey substance of the spinal cord; the intercommunicating processes can be seen much more distinctly in the microscopic slide and even in a photogram, than they appear in that figure.

The axis cylinder of each cell being a well-defined undivided process, the intercommunicating processes must be regarded as protoplasmic in the sense expressed by Deiters. Their general intercommunication cannot have any other significance than to insure equality of action in giving the impulse to the electric batteries. If that statement be admitted *the protoplasmic processes of the cells must have a conducting function.* If that be true in the Mormyrus there is no reason whatever why it should be otherwise in other vertebrates. Yet Golgi maintains that the protoplasmic processes of nerve cells are to be regarded as having a simply nutritive and therefore a non-nervous function.

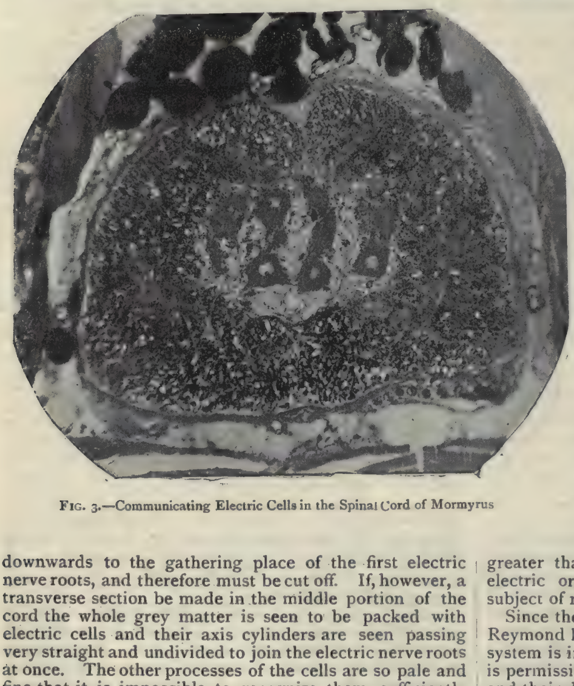

FIG. 3.—Communicating Electric Cells in the Spinal Cord of Mormyrus

There is another most remarkable fact in the organization of the Mormyrus having reference to the combined action of the electric organs on both sides. The upper as well as the lower electric nerves form a decussation outside the vertebral canal resembling the chiasma of the optic nerves. I am not acquainted with any other instance of motor nerves crossing the median plane to the other side of the body outside the cerebrospinal axis. In all other cases they are outside the brain and the spinal cord confined to their own side of the body to insure the isolated action of each muscle or group of muscles on that side. It is therefore stated that in changing the motor into an electric function these nerves at the same time became liberated from the strict rules of their predecessors. Certainly the case of Mormyrus gives a very good idea of the extraordinary power of adaptation to function with which Nature is endowed; but who can say how this particular anatomical arrangement could come about by gradual variation? I consider this difficulty far greater than that relating to the first development of electric organs in general which is so frequently the subject of reference.

Since the celebrated investigations of Prof. E. du Bois-Reymond have shown that the function of the muscular system is intimately associated with electric currents it is permissible to take them into account where muscle and their derivatives are under consideration.

I have shown elsewhere that most of the electric fishes are liable to a degeneration of the muscular system, seemingly caused—in part, at all events—by a certain lazy mode of life (disuse of organs). We therefore find along with fully developed electric tissue in the Gymnotus, nests of muscles which have not arrived at perfection. In the Mormyrus degenerating muscles in the forepart of the electric organ suggest the impression that the process of transformation is still going on. Still more is this the case in the common Raja.

Moreover, we know that the peculiar degeneration of muscular tissue into electric tissue destroys the contractile power of the muscles, but does not interfere with their electromotor properties; on the contrary the loosened and differently arranged elements of the changed muscles are more capable of producing electric currents. In that state of development which has still quite an occasional character, it seems only necessary to assume that under certain favourable circumstances the fish while trying to catch a prey or to defend itself against an enemy in the sudden excitement becomes aware of its electric power hitherto unknown to itself. On perceiving the advantage of the electric power in the struggle of life the fish might begin to use it regularly and to develop it gradually to perfection in its descendants; just as a man might one day perceive that he is endowed with the power of hypnotism, consequently learns to use it and gradually improves it.

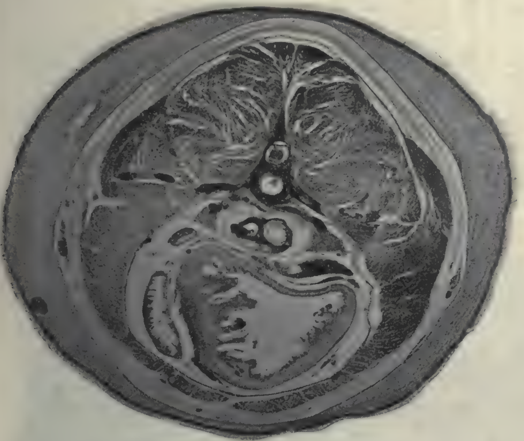

FIG. 4.—Transverse section through the body of Malapterurus with a parasite in the electric organ.

But now it is necessary to consider also the electric Shadfish of the Nile, the *Malapterurus electricus*, a powerful fish of very peculiar structure, which places it in quite a different category from the electric fishes already mentioned. A transverse section of the whole fish (Fig. 4) shows the difference at once. The body of the animal is enveloped in a very thick electric skin, constituting one electric organ. Muscular tissue is nowhere deficient, other histological elements must therefore have furnished the material for the electric plates, which are packed very close in lozenge-shaped compartments of the skin.

In my opinion the plates are nothing else than modified cells of the cutaneous glands which are plentiful in the remainder of the skin. The precise proof of that statement ought to be furnished by a complete investigation of the development of the animal, which as yet is quite unknown. But the differences between the two kinds of electric organs are so great that we are surely entitled to separate the *muscular* from the *cutaneous* electric organs.

Assuming that the origin of these cutaneous batteries differs from those developed from muscle, we cannot wonder that their functions also differ in most important points. The electric current passes through the body in a direction the opposite of that in other electric fishes. There are *only two* electric nerve fibres, one on each side, which divide and subdivide until they give off more than two million branches. We shall see that these two nerve fibres are not true axis cylinder processes of ganglion cells. Before making a more detailed reference to these interesting elements it may not be amiss to point out in the section shown in Fig. 4 the existence of an intruder, a specimen of the so-called *Filaria piscium*, which had taken up its abode in the electric organ itself. This proves that animals can become accustomed to strong electric currents without receiving injury, and it suggests that the immunity of electric fishes against their own currents and that of their young *in utero* (Torpedo) is a faculty acquired by gradual training.

The construction of the single electric nerve fibre in Malapterurus resembles to a surprising extent that of an electric cable on a minute scale. We see the tiny nerve fibre like the central wire of the cable surrounded by a little non-conducting material and held *in situ* by a sort of network; the whole being enveloped in an enormous mass of connective tissue sheaths just like a cable protected externally by numerous layers of strong material. Fig. 5 shows a transverse section of the central part only to render the details of the round fibre and supporting network more distinct. If we follow this single fibre inwards to its origin in the central nervous system we are led to *a single ganglion cell* from which the single fibre arises. There is one cell on each side of the cord, therefore just two cells in all; whereas in Mormyrus, which has the smallest number of electric cells in the fishes with electric organs of muscular origin, the cells must be estimated at more than 1500. The position of the two cells in the spinal cord of Malapterurus reminds one of Clarke's column in the cord of higher vertebrates where the cells differ in certain particulars from the motor cells. As already stated there is only one cell on each side, but that is a giant of its race. There is no real axis cylinder arising from the cell, but in place of it branched protoplasmic processes join and form a kind of perforated

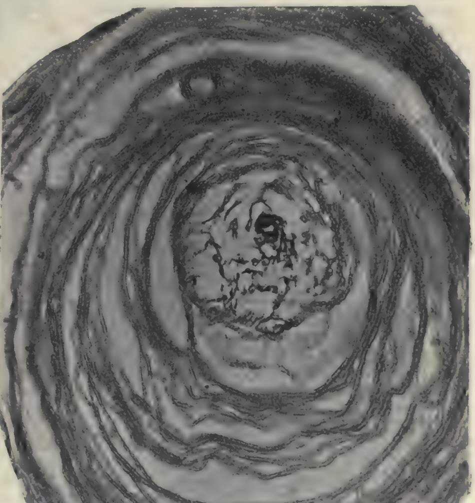

FIG. 5.—Transverse section of the central part of the electric nerve of Malapterurus.

plate beneath the cell, from which the nerve fibre starts with a broad base (Fig. 6). I consider this a chief point of difference between this peculiar cell and all the other afore-mentioned cells of a motor character. Fig. 6 gives a good idea of this magnificent histological specimen with its elegant nucleus showing its network and its nucleolus on one side.

Reviewing from a physiological standpoint the several facts stated above, we must feel convinced that the peculiar ganglion cells which are invariably found in relation to electric organs must play an essential part in bringing the electric organ into action. In my opinion that is tantamount to proof that other ganglion cells must be essential for sending nerve impulses to peripheral organs, and that the idea lately suggested by Nansen that ganglion cells have only a trophic influence on nerve tissue cannot be reasonably maintained in the face of these and similar facts. I may here refer to the well-known peculiar ganglion cells found in the motor region of the brain of higher animals, including man. Betz, who discovered them, searched for them for the purpose of stating anatomically the laws of localization found by Prof. Hitzig and myself.

It may not be out of place to adduce here another piece of evidence taken from the department of pathology. My friend and collaborator Hitzig has lately published the case of a man who died from tetanic cramp of the head. He observed that in the ganglion cells of the motor centre of the fifth nerve presiding the affected muscles there was a very singular change to be observed *in these cells only*. It appears that the bacteria of tetanus caused a granular decomposition of the protoplasm in the cells, which led to a further state of degeneration characterized by the appearance of large holes, while the other ganglion cells and the remainder of the organ appeared quite healthy. I am convinced the case shows that the cramps in the combined muscles resulted from the irritation and gradual disorganization of the ganglion cells.

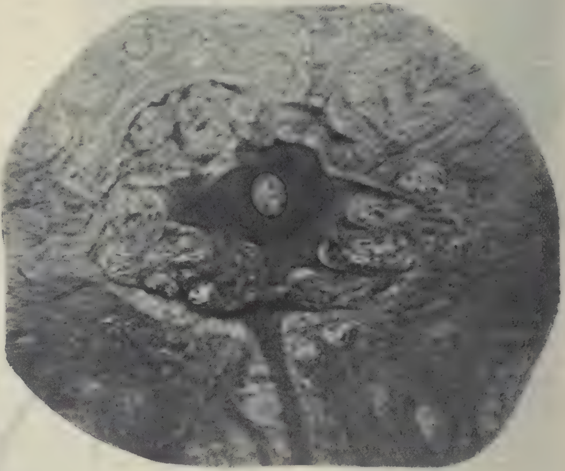

FIG. 6.—The right giant ganglion cell with the origin of its electric nerve from spinal cord of Malapterurus.

The above statements may suffice to show that the electric fishes and their nervous elements are really not such outsiders in science, and that the observations made on them should be brought into comparison and correspondence with those gathered from other sources. Indeed the histological elements in their organs are so instructive, that I would strongly recommend that the conclusions deducible from their study should be employed in maintaining well-founded former notions regarding the organization of the nervous system in vertebrates against certain revolutionary ideas of some modern authors. GUSTAV FRITSCH.

Physiological Institute, University of Berlin.

AUSTRALIAN TRAVELS.[1]

ON opening this work, one is at once struck by the beauty of the illustrations, particularly those of the New Zealand Alps. The double-page plate opposite p. 248, drawn from a photograph taken by the author, is especially worthy of remark. For effect this view may well compare with some of the most picturesque parts of Switzerland. Some of the photographs, however, have a familiar appearance to the travelled reader; one recognizes in the beautiful picture "Off the West Coast of Ceylon" (p. 300) an old friend, none the less worthy of reproduction.

The work makes no pretensions to a virgin freshness its professed object being to gather together the already published observations of the author, and to present them in a popular form. This it does very successfully, though the English reader could have dispensed with a good deal of the very apparent "padding." Thus the first twenty pages of this book of travel are devoted to the history of Australia, and remind one of Coghlan's opening chapter in the "Wealth and Progress of New South Wales": the next twelve pages on gold differ from Coghlan's second chapter, particularly in giving greater prominence to Count Strzelezki's discovery, and one regrets that n mention is made of James McBrian, who certainly ha prior claims. The author is candid in his criticisms and condemns both the theatres and University of Sydney, as being, from the German standpoint, decidedly bad. On p. 34 we come to a "Journey into New South Wales," and here commences an interesting medley of natural history, traveller's tales, and geographical investigation. In this vacation ramble Von Lendenfeld claims to have discovered the culminating point of the Australian continent in Mount Townsend, to which he assigns (by aneroid) the height of 2241 metres. The doggerel verse on p. 82, in which a red sunset is taken to indicate approaching rain, must be wrong in its meteorology, so at least it proved, a red sunset being followed, much to Lendenfeld's surprise, by a fine day. It is satisfactory to find that the signs of the weather are not inverted at the Antipodes.

The author's familiarity with glaciers and ice-action in Europe served him in good stead in the southern hemisphere. Several interesting pages are devoted to his discovery of the former existence of glaciers in the Australian Alps; though there seem to have been contemporaries in this matter, for while Von Lendenfeld's observations proved the existence of *moutonnéed* and striated surfaces down to a level of 1500 metres above the sea—Mr. James Stirling claimed to have found signs of ice-action at lower levels still, as in the neighbourhood of Omao, where they occur at 800 metres above sea-level. The historical conscience is strong in the author, or he would scarcely have troubled to recall the fact, that when his communication on the discovery of glacial markings was read before the Geological Society of London, it was received with scepticism by Prof. Bonney (and, let us add, though the author does not, by Dr. Blandford also). On turning to the *Journal* of the Society we find that Prof. Bonney considered the observations then adduced by Von Lendenfeld as insufficient to establish his conclusions, and in this opinion we fancy most geologists will be inclined to agree with him. That the conclusions were right after all is a different matter. It is to be regretted that even in this, his latest published summary, Von Lendenfeld does not always supply us with facts on which we can base an independent judgment. The personal opinion of an observer, however skilled, can be no sufficient substitute for these. A single instance will suffice. An important joint expedition was undertaken by the author and Mr. Stirling to examine into the accuracy of the latter's statements as to the downward extension of the ice. After several pages of interesting traveller's gossip we reach the result in words much to the following effect:—"After three-quarters of an hour's ride in the valley bottom we reached an old moraine, which we investigated closely. A dam 35 metres high and 200 broad composed of various (*verschieden*) great blocks of rocks with sharp angles stretched across the valley. A brook flowed through the middle. We are here at a height of from 900 to 1000 metres, and since it is a veritable moraine Stirling is right and our dispute is ended."

---

[1] "Australische Reise," by R. von Lendenfeld, pp. 325, with Illustrations. (Innsbruch: Wagner, 1892.)

We will not offend the susceptibilities of the author by questioning whether this is really a moraine: probably it is; but no convincing proof of the fact appears in the description. One would like to know whether other signs of ice-action were observed in the immediate neighbourhood, in what respects the fragments differed from each other and from those of the adjacent valley slopes, and especially what evidence existed to show that they had been carried down the valley, and how far they are removed from their source. This information could have been conveyed in a few words, and would have been welcomed by inquiring minds, who now may wonder whether after all this dam could by any chance be merely the remains of an ancient landslip. New Zealand is introduced to us on p. 161, and after a short historical account we pass on to the New Zealand Alps and fjords. With regard to the latter the author stoutly maintains their glacial origin: one of his chief arguments resting on their great depth as compared with the sea into which they open. They are apparently submerged rock basins, but although the author may be right in his contention that they are not merely moraine-dammed valleys, yet he altogether overlooks another more probable explanation, depending on unequal subsidence: submergence of the land has certainly taken place, and one has only to concede that the central mountain masses have sunk to a greater extent than the adjacent sea-floor to understand how the previously existing valleys would be converted into fjords. The greatest depth of Milford Sound is 360 metres, and one must travel (so our author tells us) at least 100 kilometres from the coast before this depth is reached at sea; now as the watershed is distant only 30 kilometres from the coast, it is at least as probable, considering the gradient, that we have to do here with differential movements of the land, as with locally concentrated erosive action.

An ingenious attempt to explain the last glacial episode leads to several bold generalizations. The author commences with the assertion that the whole of the southern hemisphere is at present much more severely glaciated than the northern, indeed he goes so far as to state that the northern hemisphere in the middle of the ice period was not much more severely glaciated than the southern is now. Since the mean temperature of the southern is not lower than that of the northern hemisphere the reason for its excessive glaciation must lie in a more uniform climate and a damper atmosphere; and these again are a direct consequence of the greater extent of the oceanic surface.

Let us now suppose the sea-level in the northern hemisphere to rise 100 metres, the lowlands will become submerged (as during the last glacial episode they apparently were) the climatal conditions will then approach those now prevailing in the southern hemisphere, and excessive glaciation will result.

But in the southern hemisphere also, the ice was formerly of much greater extent, and this is not susceptible of the same explanation, since a depression of the land would not greatly affect the existing climate. What, however, would be the effect of a depression of the sea level? The submarine slopes of most of the land in the southern hemisphere are so steep that the present distribution of land and sea would not be largely modified, though the latter should sink 300 metres; on the other hand, the increase in the height of mountains (300 metres) would lead to a descent of the snow line, the growth of snow fields, and a corresponding enlargement of glaciers. Thus the glacial episode in the northern hemisphere might be attributed to an elevation of the sea-level, that in the southern to its depression: and these changes of level may have been produced by a bodily movement of the ocean waters from one hemisphere to the other, a result itself possibly due to a shifting of the centre of gravity of the earth. The author does not explain how to shift the centre of gravity of the earth.

We notice that the author speaks with disrespect of the maps of the Tasman glacier by Mr. W. S. Green, stating that they are nothing like so good as Von Haast's; since however, later explorers prefer them to Von Lendenfeld's own, it would appear that we have here a descending scale of excellence.

After pointing out the failure of Mr. Green to reach the actual summit of Mount Cook, the author gives a glowing account of a successful ascent of his own, not of Mount Cook however, but of the Hochstetter Dome! He therefore claims to be the first who has set foot on the top of a high mountain in New Zealand. We offer him our congratulations.

In commenting on the author's style, which in its lucidity is far more English than German, we must offer a serious protest against his manner of using what he terms our "transcendentally intense adjective." Bob Acres' remark that, "The best terms will grow obsolete. Damns have had their day," does not appear to apply to Australia, where, to judge from our author, they flourish along with other survivors of a Mesozoic age.

AMERICAN FORESTRY.[1]

COMPETENT English authorities on forestry are so rare that no apology is needed for presenting some extracts from a translation from the German, of an important paper by Sir D. Brandis on American forestry. This is in continuation of a similar translation which appeared about a year ago in the columns of NATURE (vol. xliv. p. 60).

Upwards of 1,000,000 acres of forest are required for the annual supply of wooden sleepers for European railways. These forests are properly managed so as to yield a steady return, whilst nothing of the kind can be said of American forests. This explains why German foresters are interested in watching the progress of forest destruction in America, where it is now merely a question of ten or fifteen years before a timber famine must occur, which will greatly enhance the value of European forests.

---

[1] "The Silva of North America." By C. S. Sergent, vols. i.–iv. (Boston and New York. Houghton, Mifflin and Co., 1891–92). Notes on the above by Sir D. Brandis, K.C.I.E., F.R.S., in *Zeitschrift für Forst und Jagdwesen*, October, 1892.

Brandis explains the present lamentable state of affairs in the United States, as follows:—The Timber Culture Act, which was in force in certain of the States, provided that settlers should plant up with trees one quarter of the area allotted to them, and it was thus hoped to obtain forests in the treeless regions between the Rocky Mountains and the Mississippi river. Large tracts of land have been occupied under this Act, but very little progress has been made in afforestation. It is not difficult in the Republic for people to neglect engagements they have made with the State. It has been recognized for some time past that this law has been practically of little use, and it was therefore abrogated in March, 1891. The law abrogating it, in section 24, empowered the President to demarcate and reserve certain tracts of State forest. Great hopes were therefore entertained, and soon afterwards a proclamation was issued largely extending the Yellowstone Park, in Montana, on the borders of Canada.

This measure had been strongly supported for some time past by the American Forestry Association. The Park is a mountain forest tract on the water-parting between the Rivers Columbia and Missouri, and its preservation and proper management is of immense importance. In October, 1891, the extensive forest tract in Colorado in the Rocky Mountains, in which several large tributaries of the Colorado river have their rise, and containing 1,365,000 acres, was proclaimed as the White River Forest Reserve. It was also expected that a portion of the western slopes of the Sierra Nevada, bordering on the Yosemite National Park, and other localities where the *Sequoia gigantea* flourishes, would be proclaimed as State reserves. These two national parks were previously reserved under older laws. The numerous intelligent friends of forestry in America confidently expected that a beginning would now be made in the demarcation of extensive State forest reserves, and in their scientific management.

The most recent news from America, however, has thoroughly upset these expectations. A Bill has been introduced into Congress, to hand over most of the Yellowstone forest reserve to a railway company. It is considered certain that this Bill will pass the Lower House, and it is not expected that the Senate will refuse to sanction it. Wood merchants, mining speculators, and sheep owners are vigorously agitating against the proposed reserve in the Sierra Nevada, and it is feared that their agitation will carry the day.

The American Forestry Association, which held its tenth annual meeting last January, has "memorialized" the President that instead of making a few reserves here and there, he should proclaim the reservation of all State forests still left to the Union, and arrange for their proper management. Friends of the forest are numerous in America, and insight into the essential necessity of forest protection is spreading, owing to the numbers of Americans who travel in Europe, but in a land where the dollar rules, and where an individual who will not recognize its authority is considered a fool, any steady progress towards State forest management cannot be expected.

Bernhard Fernow, the chief of the Forestry Branch of the Ministry of Agriculture at Washington, still hopes for action in this direction on the part of Congress and the State Executive. At the last meeting of the Forestry Association he rightly urged that æsthetic and sentimental grounds for improving American forests must be left entirely in the background. Only where important material interests are concerned, such as securing a continuous supply of wood, or a supply of water, or climatic considerations, should the State limit the freedom of its citizens in dealing with forests. If, however, for urgent reasons of public utility, it should be necessary to reserve a forest, the State should not be contented with merely demarcating and protecting it, but should introduce scientific management, so that the neighbouring populations may be able to utilize the forest produce; and in any case, all pre-existing rights acquired by the people in the forests should be strictly protected. Fernow concludes with the strongly-expressed advice that a law should be passed reserving the relics of the forests of the Union, and preventing any fresh alienations. He firmly believes that such a law is most urgently required. It is, however, quite a different matter for Congress to pass any such law, though more may perhaps be expected from the separate States in the Union, and in those of New York and California some rather halting steps have been taken in the right direction.

As matters stand at present in the United States, it is pretty obvious that a time will come when landowners will look upon their private forests as a good investment, for prices of wood and other forest produce are steadily rising. Little progress has, however, yet been made in this direction, and recent attempts made by some rich men to manage their forests properly with advantage have failed.

Sir Dietrich Brandis then turns to the progress made in the study of American forest trees, and states that literature on the subject is pretty abundant, but is after all merely thrashing straw. What is wanted in America is a practical proof that in forests of the Weymouth pine, of Minnesota, or of Californian red wood, or of Douglas fir in Washington and Oregon, or in the splendid mixed broad-leaved forests of the Alleghany mountains, good forest management will prove more remunerative than wasteful pillage (*Raubbau*).

The remainder of Brandis's paper is chiefly of botanical interest, and greatly praises Sergent's magnificent work. One other passage is too interesting to be omitted. It refers to the mesquit tree, *Prosopis juliflora*, which belongs to the dry zone in the south-west of the United States, and is also found in Mexico, and in the Andes as far as Chili and Argentina. In the river valleys of Arizona, where, although the air is dry, yet subsoil water is near the surface of the ground, this species forms extensive forests. On drier soils the aerial parts of the tree are reduced, but the root system is greatly extended. Sergent states that while the stem may be only a few inches high, and may only bear a few leaves, yet the tap root goes straight down to the subsoil water, and the aerial growth of the tree furnishes a clear indication of the depth at which the latter may be found.

Wherever the mesquit is a tree the subsoil water is forty to fifty feet down, where it is a small shrub it is from fifty to sixty feet down, and wherever the roots descend over sixty feet, the plant is not more than two or three feet high. In the scantily-wooded districts, where the mesquit tree grows, its roots yield most of the firewood, and are dug up, or dragged by oxen from the ground. *Prosopis spicigera* in the drier parts of India similarly furnishes fuel and cattle fodder in the Punjab, Sindh, and parts of Berar. This tree, there termed the *Jhand*, sends down its roots to a depth of fifty feet and more, to the subsoil water, and thus produces wood in a dry country, providing the peasant with fuel and wood for his plough.

W. R. Fisher.

JOHN STRONG NEWBERRY.

It is not only in the United States that the death of this veteran of scientific research will bring widespread regret. To many geologists and palæontologists in this country and on the Continent he was personally known, and those whom he honoured with his friendship will feel keenly the loss they now sustain. He was born at New Windsor, Connecticut, on December 22, 1822, and took the degree of M.D. from the Cleveland Medical College, Ohio, in 1848. Before beginning the practice of medicine, which he intended to be his occupation in life, he spent two years in Europe. During his stay at that time in Paris he acquired a good knowledge of the French language, and had many opportunities of cultivating a love of science, which soon manifested itself as one of his distinguishing characteristics. Returning to his native country, he began practice as a medical man at Cleveland in 1851. Even at the outset of his professional work he contrived to find time also for scientific enquiry. His first published paper appeared in the same year in which he started in his medical profession. It is devoted to the geographical distribution of land and fresh-water shells.

But he soon entered upon the two branches of geological investigation in which he was to make his name familiar all over the civilized world—the study of fossil botany and of fossil fishes. As early as the year 1853 he made his first contribution to the history of Carboniferous plants, and three years later his earliest memoir on fossil fishes was published. By this time his scientific acquirements and enthusiasm were widely known. Hence when an expedition under Lieutenant Ives was organized for the exploration of the Colorado River of the West, Newberry was selected to accompany it, and to take charge of the observations to be made in natural history. His geological contribution to the famous Report at once placed him in the very front rank of American geology. His account of the geological structure of the region traversed by the expedition, and of the marvellous denudation of the cañons, will always remain as one of the landmarks of geological progress.

He had now been touched by the fascination of exploration in the far west. The drudgery of medical practice became irksome to him, so that when in the year following his return from Colorado the offer was made to him to take part in another expedition, he gladly availed himself of the opportunity. He accordingly accompanied Captain Macomb in an exploring expedition in the summer of 1859, from Santa Fé, New Mexico, to the junction of the Grand and Green Rivers of the Grand Colorado. This journey forms the subject of another masterly report by him, which, however, was not published for some sixteen years.

The shadows of the coming great Civil War were already falling on the United States, when Newberry was at work on the preparation of the record of the results of his western journeys. The storm at last burst in 1861, the same year in which his Colorado report was issued. Among the many scientific men who placed their services at the disposal of the North, Newberry took a foremost place. His medical skill and wide general scientific knowledge enabled him to be of great use to the army. He specially distinguished himself in the organization and administration of the hospital department. Among the reminiscences of his not uneventful life he had many graphic tales to tell of his experiences during that momentous epoch in the history of the United States. After the close of the war in 1865 he returned with renewed ardour to his scientific labours, and specially devoted his energies to the study of the ancient floras and fish-faunas of North America. Among his numerous memoirs on these subjects the two large monographs forming vols. xiv. and xvi. of the series published by the United States Geological Survey are specially worthy of notice. But they represent only a part of the enormous mass of material which he had worked over.

Prof. Newberry early in his career saw how great was the aid which geology could afford in the development of the mineral industries of his native country, and he gave himself with great energy to the practical applications of the science. He became one of the highest authorities on mining matters in the country, and he was mainly instrumental in the equipment of the great mining school of Columbia College, New York. He occupied the Chair of Geology in that establishment, and threw himself heart and soul into its duties. At last, in the midst of his work and honours, a stroke of paralysis disabled him from active duties, and he grew gradually feebler until his death. With him American science loses one of its most honoured and distinguished cultivators. His piercing eyes and well-cut features made him a marked figure in any assembly, while his courtesy and gentleness, and his unfailing helpfulness and serenity, gave him a charm which will endear his memory to a wide circle of friends. A. G.

NOTES.

All entomologists in the country will learn with great satisfaction that the Treasury has consented, on the recommendation of the Trustees of the British Museum, to make provision in the estimates for the coming financial year for the purchase of Mr. Pascoe's well-known collection of insects. The importance of the acquisition of this collection by the nation is very great, as it contains an immense number of types, especially of the families Longicornes and Curculiones, to which Mr. Pascoe devoted so much attention for a period of more than forty years. Its dispersal or removal to a foreign country would have been an irreparable loss to British entomologists.

The medals and funds to be given at the anniversary meeting of the Geological Society of London on February 17 next have been awarded as follows: The Wollaston Medal to Prof. N. S. Maskelyne, F.R.S.; the Murchison Medal to the Rev. O. Fisher, the Lyell Medal to Mr. E. T. Newton; and the Bigsby Medal to Prof. W. J. Sollas, F.R.S.; the balance of the proceeds of the Wollaston fund to Mr. J. G. Goodchild; that of the Murchison fund to Mr. G. J. Williams; and that of the Lyell fund to Miss C. A. Raisin and Mr. A. Leeds.

Between June 10 and 18 the University of Montpellier will celebrate the third centenary of the foundation of its Botanic Garden, on which occasion it is intended to invite a general congress of the botanists of all nations.

A meeting of the Association for the Improvement o Geometrical Teaching was held on January 14, at University College, Gower Street, the chair being taken by the Master of St. John's College, Cambridge. The reports of the Council and treasurer having been read and adopted, Dr. Wormell was elected President for 1893, the hon. secretaries (Mr. E. M. Langley, 16, Adelaide Square, Bedford, and Mr. C. Pendelbury, 4, Glazbury Road, W. Kensington), and the other members of the Council being re-elected. Dr. Wormell having taken the chair, Mrs. Bryant gave a model lesson on geometry to a class of about twenty ladies. After an adjournment papers were read by Mr. G. Heppel on the use of history in teaching mathematics, and by Mr. F. E. Marshall on the teaching of elementary arithmetic. The attendance was larger than usual, and interesting discussions followed the lesson and the papers.

A departmental committee, consisting of officers of the Charity Commission, the Education Department, and the Department of Science and Art has been appointed by Mr. Acland, Vice-President of the Committee of Council on Education, to consider the question of the organization of secondary education in England and Wales, and the relation of the Departments among themselves in connection with this subject. The Committee consists of the following members:—The Vice-President of the Council (chairman), Sir H. Longley, K.C.B., Chief Charity Commissioner, Mr. T. E. Ellis, M.P., Parliamentary Charity Commissioner, and Mr. Fearon, Secretary to the

Charity Commissioners, representing the Charity Commission; Mr. Kekewich, C.B., Secretary to the Committee of Council on Education, and the Rev. T. W. Sharpe, her Majesty's Senior Chief Inspector of Schools, representing the Education Department; and Major-General Donnelly, C.B., Secretary of the Department of Science and Art, Captain Abney, C.B., F.R.S., Assistant-Director for Science, and Mr. Armstrong, Director for Art, representing the Department of Science and Art, Mr. H. W. Simpkinson, Examiner in the Education Department, acts as Secretary to the Committee.

On the 25th inst. an influential deputation will wait upon the President of the Board of Trade to urge the adoption of the decimal system of coinage and weights and measures in Great Britain. Among those who propose to form part of the deputation are the Agents-General for Victoria, Queensland, and the Cape, and several prominent members of the various chambers of commerce.

The Infant University of Chicago seems to be resolved to arrange its staff of teachers on a scale commensurate with the size of the North American Continent. Thus, the Department of Geology is placed in the hands of no fewer than seven distinct professors and two assistant professors, each taking some special branch of this wide science under the competent leadership of Prof. T. C. Chamberlin. Three of the professors are non-resident, but they will probably give occasional lectures, and will at least direct the studies in their own branches of research.

Mr. John D. Rockefeller, who had already presented the University of Chicago with 2,600,000 dollars, has now given it another million. The university owns land, buildings, and other property valued at £1,400,000 sterling, and the principal is ambitious enough to hope that in course of time it may have "such an array of magnificent buildings as one sees at Oxford or Cambridge."

A botanical laboratory has been established at Eustis, Lake co., Florida, chiefly for the investigation of diseases of the orange and other species of *Citrus*, under the direction of Prof. W. T. Swingle. The anatomy, physiology, and pathology of other sub-tropical economic plants will also be investigated.

On Saturday last Prof. Flinders Petrie delivered his first lecture as professor of Egyptology at University College, Gower Street. In the course of the lecture he said that, besides more than a thousand photographs and various impressions or "squeezes" of sculpture, a collection of original objects would be exhibited for the close examination of students. Miss Edwards had formed a collection with much care—as complete and typical as possible. He hoped also to place on loan his own collection, and to have a series of annual loan exhibitions drawn from the many valuable private collections in England. There would thus be found a collection of deities, the most complete collection of scarabs, the only chronological collection of beads, a dated series of pottery, the largest collection of funeral cones, and also of Egyptian weights. In certain lines of study their museum would not be merely supplemental, but would be in advance of any historical museums. He proposed to give a series of lectures in the autumn and spring, and would prepare students who might wish to undertake practical work in Egypt, where he would spend the time before Christmas to Easter.

Mr. Rowland Ward is exhibiting in his studio a valuable collection of African trophies and curiosities, most of which have been brought to England by Captain Lugard and Mr. F. C. Selous. Besides natural history specimens, the collection includes many weapons and products of native art.

Another severe loss has been sustained by science in Russia through the death of the well-known mineralogist, Nikolai Ivanovitch Koksharoff. He died at St. Petersburg on January 2. He was born on December 2, 1818, in West Siberia, in a village near which at that time was the fort of Ust-Kamenogorsk, and he made his studies in the Mining Institute at St. Petersburg. In 1841, when he was a mining engineer in the Urals, he accompanied Murchison on his journey to Russia and to the Urals, and the intercourse with the great geologist led him to adopt a scientific career. He spent the next three years studying in Western Europe, and on his return he devoted himself entirely to minerology, and especially to goniometric measurements of minerals, in which he was so much aided by his wife that his numerous writings on this subject are as much her work as his. He lectured in his early years on geology and physical geography, but later on devoted himself almost entirely to the description of Russian minerals, of which he discovered and described many new ones. His chief works are embodied in eleven large quarto volumes of "Beiträge zur Mineralogie Russlands," illustrated with numerous plates. The twelfth volume was in type when he died. In 1866 he was made a member of the St. Petersburg Academy of Sciences, and many scientific bodies of Western Europe elected him corresponding or honorary member.

During the past week the weather has been of a very unsettled character; at first an anticyclone lay over the greater part of these islands, while areas of low pressure were situated over the North Sea and to the west of Norway. With these conditions the weather became warmer in this country, the daily maxima varying from 40° to 46°, but over the Continent very low temperatures continued to be registered, the minima in Sweden varying from 60° to 65° below the freezing point, while exceptionally severe weather also prevailed over France and Germany. On Sunday a depression was passing to the southward of these islands, and under its influence north-easterly gales were experienced in the eastern and southern parts of England; a sharp frost occurred over this country, accompanied by snow in most parts, while a thaw set in over Scotland and rapdidly spread southwards, accompanied by rain, the maximum temperatures reaching from 45° to 50°. Subsequently the conditions were again becoming anti-cyclonic, accompanied by a return of colder weather, but they were not at all settled; snow was falling on Tuesday in the south of England. For the week ending the 14th instant the temperature was everywhere below the mean, the deficit ranging from 2° to 5°. The amount of bright sunshine exceeded the average in the north and west of Scotland and in the south-west of England; elsewhere the amount recorded was very small, being only 3 per cent. in the north-west of England.

Das Wetter of December last contains an account of a heavy thunderstorm which occurred at Paderborn on August 9, 1892, in which a number of living pond mussels were mixed with the rain. The observer who is in connection with the Berlin Metereological Office sent a detailed account of the strange occurrence, and a specimen was forwarded to the Museum at Berlin, which stated that it was the *Anodonta anatina* (L.). A yellowish cloud attracted the attention of several people, both from its colour and the rapidity of its motion, when suddenly it burst, a torrential rain fell with a rattling sound, and immediately afterwards the pavement was found to be covered with hundreds of the mussels. Further details will be published in the reports of the Berlin Office, but the only possible explanation seems to be that the water of a river in the neighbourhood was drawn up by a passing tornado, and afterwards deposited its living burden at the place in question.

Mr. C. F. MAXWELL writes to *Science* from Dublin, Texas, that on the night of November 29, about 8 o'clock, a very large meteor was seen passing westward, a little to the south of that place. Just as it seemed to be passing the body exploded, producing a sound that was distinctly heard, resembling that of a rocket explosion or a pistol-shot. After the explosion a body half as large as a full moon moved away to the westward, making a hissing or frying sound. Mr. Maxwell has seen no one who saw the meteor before the explosion. The whole country was brilliantly lighted for a moment as if by a continued electric discharge, but at the time of the explosion the light was red and blue, or perhaps violet. The sound of the explosion was heard by parties five miles west and seven miles east of Dublin, who could not have been less than ten miles apart on an air-line, and they report the sound together with the other phenomena to have been about the same as they were at Dublin.

WHEN commanding the *Naiade* during the cyclone of November 6, 1891, Rear Admiral Cavelier de Cuverville had the opportunity of testing the efficiency of oil in calming the troubled waves of the North Atlantic. The last number of the *Revue Maritime* contains an account of his experiences and conclusions. When the waves threatened to become dangerous he gave orders to fill two coal sacks with tow steeped in oil, one of them to be suspended freely at the extremity of a spar spanned to the cat-head, the other near the bridge. The effect was excellent. No seas were shipped, and the vessel escaped without breaking a spar. It appears that the oil takes effect upon the "breakers" due to horizontal translation produced by the wind, leaving the orbital motion or "swell" unaffected. The former is the only element of danger in a rough sea. It was found that two sacks, filled with 5 kgr. of tow, holding 5 litres of colza or machine oil each, were sufficient to protect a vessel 75 m. long. The oil had to be renewed every six hours. Too much oil has the disadvantage of spreading more slowly, and theoretically the best system of distribution would be one in which the oil would reach the surface from below in a large number of small drops.

HERR J. NAUE has been fortunate enough to discover at a prehistoric station near Schaffhausen a piece of limestone, on both sides of which are drawings like those which have been found in caves in France and in the cave at Thayngen. It was found in the lowest part of the yellow "Kulturschicht" among bones and teeth of reindeer, horses, and other animals. On one side are a horse, a foal, and a reindeer, while several horses appear on the other. The style is not so fine as that of the Thayngen drawings, but, according to Herr Naue, they display a power of keen observation, and he points out that it was more difficult to work on stone than on a bone still fresh.

THE remarkable address delivered by Prof. Virchow on his assumption of the office of Rector of the University of Berlin has been issued by the German publisher, August Hirschwald, of that city. The title is "Lernen und Forschen."

THE *Pharmaceutical Journal* of the present week prints the first of what promises to be a good series of papers, which are intended to make bacteriology intelligible and interesting to students, and to be of some practical value to pharmacists in business. The *Journal* rightly thinks that the time has come when pharmacists ought to make themselves familiar with the principles of "this newest department of experimental science."

LAST week Lord Kelvin delivered an interesting speech at a dinner given to the members of the new watch factory at Prescot. He said it was something to be proud of that the article they were making was a triumph of mechanism. There was nothing in the whole of scientific art, nothing in the results of mechanics applied to the useful purposes for mankind, that was a more splendid success than the science of watchmaking. He had been all his life engaged more or less with scientific experiments, with measurements, and with instruments which their French friends would call instruments of precision. They knew something of instruments of precision in electricity, and they were thankful if they could make a measurement which was accurate to one-tenth or one-twentieth per cent. But what did watchmaking do? The commonest cheap watch—cheap but good—which would issue from the Prescot works would keep time to a minute a week. Now a minute a week, if they made a little calculation, was something like one-hundredth per cent. of accuracy, or just about ten times as accurate as they considered exceedingly good work in electrical measurements.

AT a recent meeting of the College of Preceptors, Mr. Foster Watson read a remarkably interesting paper on Richard Mulcaster, who was head-master of St. Paul's School from 1596 to 1598. The paper is printed in the current number of the *Educational Times*. Mulcaster's ideas were in some respects far ahead of those of his time. The following, according to Mr. Watson, were his "main educational contentions":—(1) Culture and learning for those who have the wit to profit by it, whether rich or poor. Adequate knowledge for those who go into trade. (2) Education for girls and women, as well as boys and men. Higher education for girls who have good abilities. (3) Training colleges for teachers. (4) Physical training for all—boys and girls, teachers and pupils, and this to be continued in after-life. (5) Liberal education, with disinterested aims for the elementary schools. (6) The best masters to take the lowest classes. (7) Drawing and music to be taught in every school, not as "extras," but as essentials. "You will notice," says Mr. Watson, "that the last-named five aims are only within the field of discussion even yet; they are not *faits accomplis*. All this time they have been in Mulcaster's book, and Mulcaster's book—a few copies of it, very few—have been gathering dust."

THE Association of Officers of Colleges in New England have recommended the gradual adoption of the following changes in the curriculum of New England grammar schools:—(1) The introduction of elementary natural history into the earlier years of the programme as a substantial subject, to be taught by demonstrations and practical exercises rather than from books. (2) The introduction of elementary physics into the later years of the programme as a substantial subject, to be taught by the experimental or laboratory method, and to include exact weighing and measuring by the pupils themselves. (3) The introduction of elementary algebra at an age not later than twelve years. (4) The introduction of elementary plane geometry at an age not later than thirteen years. (5) The offering of opportunity to study French, or German, or Latin, or any two of these languages from and after the age of ten years. (6) The increase of attention in all class-room exercises in every study to the correct and facile use of the English language. In order to make room in the programme for these new subjects, the association recommends that the time allotted to arithmetic, geography, and English grammar be reduced to whatever extent may be necessary. The association explains that it makes these recommendations in the interest of the public school system as a whole, but that most of them are offered more particularly in the interest of those children whose education is not to be continued beyond the grammar school.

MR. WALDO DENNIS gives in *Science* a minute and very interesting account of a snake which he watched for an hour in the woods one morning in July last. It went straight up a tree "without crook or turn," and by-and-by lay still for a while, basking in the sun. Mr. Dennis notes that while in this position it lifted up its head four or five inches and gaped. Its mouth opened very wide; and when the mouth was closing, the nervous spasm, only half expended, again seized upon the jaws, whereupon they went wider than before, the spasm exhausting itself at last in a parting wriggle or two to the head. "So natural," says Mr. Dennis, "was this novel performance, that I involuntarily listened for that characteristic accompaniment, the little agonizing whine so common with the dog, and and not uncommon with us."

FEW things are more frequently said than that diseases of the nervous system, especially those of a hysterical character, have increased with the growth of civilization. Dr. de la Tourette has been trying to show, in the *Journal de Médecine*, that this is an error, and Dr. D. G. Brinton, in *Science*, expresses cordial agreement with him. Travellers who give the soundest information on the subject, says Dr. Brinton, report that in uncultivated nations violent and epidemic nervous seizures are very common. Castren describes them among the Sibiric tribes. An unexpected blow on the outside of a tent will throw its occupants into spasms. The early Jesuit missionaries paint extraordinary pictures of epidemic nervous maladies among the Iroquois and Hurons. During the Middle Ages there were scenes of this kind which are impossible to-day.

THE question as to whether electrification is produced by the friction of gases has been exhaustively dealt with by Mr. Wesendonck, who gives an account of his results in *Wiedemann's Annalen*. The apparatus resembled that employed by Faraday with negative results, in the case of dry air. Mr. Wesendonck used air compressed to 100 atmospheres in Elkan steel bombs of 1000 litre capacity. This was passed through a brass tube widening out into a cone into which a similar cone could be screwed from the opposite direction, so as to leave a conical path for the air issuing from the bomb. The second cone was connected to a delicate electrometer, which indicated any electrification produced by the impact of the air. Ordinary air was thus found to give considerable negative charges, up to 1½ volt, if the cones were far apart, and positive charges if they were screwed up close. But no electrification was produced when the air had been previously freed from dust and moisture. Oxygen behaved in the same way. Carbonic acid, evaporated from the liquid state, imparted a strong positive charge to the brass, which was, however, reversed as soon as the cold led to the precipitation of water vapour. Ordinary atmospheric dust was found to electrify the brass negatively, the charge being increased by previous drying. It seems, therefore, that pure gases are incapable of producing electrification by friction, and that the effects observed are conditioned by the presence of minute solid or liquid particles.

FISHES in badly-ventilated aquaria give various signs of oppression, such as restlessness, frequent gasping, mounting to the surface, leaping into the air, &c. Experiments have been recently made by Messrs. Duncan and Hoppe-Seyler (*Zeitschrift für Phys. Chemie*) to ascertain to what point the oxygen-content of the water may be lowered before fishes indicate uneasiness. They were made with tench, trout, and crayfish in an elliptical glass vessel, with pipes for injecting and removing water and air, &c., in one case a pipe communicating with a chamber in which was a live rabbit, conveyed to the fishes air impoverished by the latter's breathing, while the behaviour of rabbits and fishes in the same air could be compared. With 4 to 3 cubic centimetres O in the litre of water, the fishes seemed well and content, and with the corresponding O tension in the air (8 to 11 volume-percentage) the rabbit was in no difficulty. With 1·7 to 0·8 cubic centimetres O in the water, the trout were evidently ill at ease, and, if it continued, they died. The tench and crayfish, however, stood still further reductions, the former finding relief at the surface. Reduction of the O to zero soon produced the worst symptoms.

IT was long ago shown by Sir J. B. Lawes that plants on ground that has been long without manure evaporate more water than those on good ground. Further research has proved that transpiration is not proportional to leafy development, for it largely depends on the activity of the roots, as well as evaporative surface. M. Dehérain has lately (*Ann. Agr.*) been led to investigate the influence of manure on the development of roots; and he finds that roots in unmanured ground have a much larger growth than in manured, having to spread more in search of the scanty nutriment. If, then, a plant with small leafy growth, evaporates more water relatively than one with large, it is probably due to large root-growth procuring more water. The observation of Volkens is cited, that desert plants have extraordinarily long roots. Further, M. Dehérain points out, the solar rays falling on a plant have a twofold work to do, viz. assimilation and transpiration. And these are complementary. In strong leafy plants there is vigorous assimilation, so that transpiration is limited; while in the leaves (with little chlorophyll) of an "anæmic" plant a larger fraction of the solar energy is given to transpiration.

IN the *American Geologist* an account is given of a preliminary examination of some specimens of a coaly mineral, having the general properties of a cannel, from the Kootanie and Lower Cretaceous of British Columbia. Their examination was of more than ordinary interest on account of their peculiar physical constitution and the great difficulty of ascertaining their connection with any of the materials ordinarily known to contribute to coal formation. The main characteristics of the mineral are the total absence of structure, and the presence of tubular ramuli resembling fungus mycelia, as well as rounded cavities. Angular fragments of material of the same nature as the larger rod-like bodies appear in the sections, and an amorphous substance either occurring in distinct flakes or acting as a cement to unite the rods. Mr. Penhallow's examination has made it probable that the origin of these coals must be sought in some other direction than modified vegetable structure. It is suggested that they represent a form of fossil resin accumulated during a period when resin-bearing trees were very abundant, and possessed a structure favouring the rapid disintegration of organic tissue.

A YOUNG lady in America seems to have the power of awakening not only the intelligence but the affections of insects. Her experiences are recorded in *Science* by a friend of hers, who signs himself "B." In September some one gave her a beetle, which is described as a specimen of *Pelidnota punctata* Linn. At first she kept it in a small box, feeding it with grass, leaves, and small pieces of fruits, such as peaches, pears, &c. Occasionally she would give it a drop of water to sip. It would sometimes bite a little out of a leaf, would eat the fruits, and would take water eagerly. From the first she would take the insect in her fingers several times a day and stroke or caress it, also putting it to her lips and talking to it all the while she handled it. When she put it to her lips it would brush its antennæ over them with a gentle, caressing motion. When she left her room she would shut it up in its box. One day, about two weeks after she received it, she was called out suddenly and neglected this precaution. She was absent for some time, and when she returned the insect was not in its box nor anywhere to be seen. Fearing that she might injure it, she stood still and called "Buggie, buggie," when it came crawling from its retreat towards her. "After this," says "B.," "she would frequently leave it free in the room when she went out, and when she returned, if the insect was not in sight, she would call it, and it would crawl or fly to her. As this was continued, it would more and more frequently fly to her instead of crawling, until at last it flew nearly every time it was called. When it came in this way she would put it to her lips or to her nose, and the insect would appear to be pleased, moving its antennæ gently over her lips, or taking the end of her nose between them and touching it with a patting motion." Unfortunately this interesting beetle lost its liveliness in winter. It was placed on a cloth above the kitchen boiler, where it revived to some extent ; but in December it accidentally fell to the floor and soon afterwards died.

THE annual report of the U.S. Commission of Patents for the year 1891 has been issued. In addition to the usual statistical information there are added to this report two tables and two diagrams illustrative of the growth of patent-granting from 1790 to 1890, the first century of the existence of the American patent system. The first table gives the patents granted in that period by years and by States to American citizens. The second table does the same for patents granted to citizens of foreign countries. The first diagram has one line illustrating graphically the growth of patent-granting during the century, along with another line denoting the increase of population in the same period. The second diagram has one line illustrating the growth per capita of patent-granting as a whole during the century, and other lines illustrating the growth per capita of patent-granting in the States by groups of States. There is also a list of patentees and their improvements, by years, prior to the year 1800.

THE first volume of the *Irish Naturalist*, a monthly journal of general Irish natural history, has just been published, and a very interesting volume it is. The editors are Mr. G. H. Carpenter and Mr. R. Lloyd Praeger, and they have secured from able contributors many good articles on subjects which cannot fail to be attractive to Irish readers. The volume also records work done by some of the foremost of the Irish scientific societies.

THE Bureau des Longitudes has issued, through Messrs. Gauthier-Villars et Fils, its "Annuaire" for the year 1893. It contains, as usual, a great mass of scientific information, clearly arranged. Among its "notices" is an interesting paper upon the observatory of Mont Blanc, by M. J. Janssen.

THE Belgian Royal Academy of Science, Letters, and Art has also issued its "Annuaire." Among the contents is a rather elaborate memoir of Jean Servais Stas, accompanied by an excellent portrait.

MESSRS. CHARLES GRIFFIN AND CO. have published a ninth edition of "A Pocket Book of Electrical Rules and Tables for the Use of Electricians and Engineers," by John Munro and Andrew Jamieson. The authors state that the work has been carefully revised and enriched with fresh matter, including several important communications by leading authorities on electro-technics.

MESSRS. GEORGE BELL AND SONS have issued the first portion of a supplement to the third edition of "English Botany, or Coloured Figures of British Plants." This part has been prepared by Mr. N. E. Brown. The rest will be done by Mr. Arthur Bennett.

IN our review of "Modern Mechanism" last week (p. 242) a typical American express locomotive with 20 × 24 cylinders was said to be less powerful than an 18 × 26 cylinder British engine. This should, of course, be reversed, the American engine being the more powerful.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus* ♀) from India, presented by Mr. F. Skinner ; eleven Tuatera Lizards (*Sphenodon punctatus*) from Stephen's Island, Cook's Straits, New Zealand, presented by Captain E. A. Findlay ; a Puff Adder (*Vipera arietans*) from East Africa, presented by the Directors of the British East African Company ; a Vulpine Phalanger (*Phalangista vulpina*), from Australia ; a a Stanleyan Chevrotain (*Tragulus stanleyanus* ♂) from Java, deposited ; a Sanderling (*Calidris arenaria*), European ; two Brown Capuchins (*Cebus fatuellus*), an Azara's Fox (*Canis azaræ*), a Ring-tailed Coati (*Nasua rufa*), seven Glossy Ibises (*Plegadis falcinellus*), a Brown Milvago (*Milvago chimango*), four Barn Owls (*Strix flammea*), a Ypecaha Rail (*Aramides ypecaha*), a Chilian Pintail (*Dafila spinicanda*), a Geoffroy's Terrapin (*Platemys geoffroyana*) from South America, purchased ; a Hog Deer (*Cervus porcinus*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

COMET HOLMES.—The following telegram was received from Dr. Copeland on Tuesday evening :—"Comet Holmes reported suddenly brighter. Stellar" (nucleus). We therefore continue the ephemeris. (Schulhof, for Paris, midnight.)

Date	R.A app. h. m. s.	Decl. app. ° ′
Jan. 19 ...	1 25 53·2 ...	+33 39
20 ...	27 13·7 ...	39
21 ...	28 35·1 ...	39
22 ...	29 57·2 ...	39
23 ...	31 20·1 ...	40
24 ...	32 43·7 ...	40
25 ...	34 8·0 ...	41
26 ...	1 35 33·0 ...	+33 42

The comet is now almost midway between β Andromedæ and α Trianguli.

BURNHAM'S DOUBLE-STAR OBSERVATIONS.—Mr. Burnham's splendid series of double-star measures, made chiefly with the 3-foot refractor at the Lick Observatory during the first six months of 1892, are published in *Ast. Nach.* No. 3141. He states that the superiority of the great telescope for this work has been fully demonstrated. In the present list there are micrometric measures of eight new double stars, and additional measures of 170 old ones. χ Pegasi has completed more than one revolution since its discovery in 1880, the period being about eleven and a half years, which "is probably shorter than that of any other known pair in the heavens."

Mr. Burnham's connection with the Lick Observatory having permanently ended in June last, the present list of measures concludes his work on double stars. It is to be hoped that the field of work which he has so brilliantly occupied will not be neglected in the future.

EPHEMERIS OF COMET BROOKS.—The following is a continuation of Kreutz's ephemeris for Berlin, midnight :—

Date.	R.A. (app.) h. m. s.	Decl. (app.) ° ′	Log *r*.	Log Δ.
Jan. 19 ...	22 58 23 ...	+ 48 59·3 ...	0·0835 ...	9·9670

26 ...	23 35 17 ...	+ 40 29·6 ...	0·0917 ...	0·0468

THE ECLIPSE OF APRIL 16, 1893.—In a communication to the Astronomical Society of France, M. de la Baume Pluvinel indicates some of the points to which attention should be directed in the eclipse of the sun in April. In the first place, he does not think any of the precious moments of totality need be devoted to the study of prominences, as these can now be completely studied at any time. The investigation of the corona is all-important, and attempts should be made to obtain photographs showing its general aspect with various exposures, as well as photographs of its spectrum. The different parts of the corona are of such varying brightness that it will be impossible to obtain all the details with a single exposure. For the spectroscopic work it is also recommended that isochromatic plates be employed, with special reference to the distribution of the material which gives the green line 1474 Kirchoff. Mr. Lockyer proposes to use an objective prism, so as to obtain monochromatic images of the corona, that is, rings corresponding to each elementary radiation of the coronal light. This method will not only give the spectrum of the corona, but the distribution of each spectrum line over the whole of it. The problem of the "reversing layer" is also wanting definite solution, and it is pointed out that instantaneous photographs may settle the question once for all. M. Pluvinel also points out the importance of noting the presence or absence of the hydrocarbon bands suspected by Tacchini in 1883, as this observation may throw further light on the analogy between the corona and the tails of comets.

Photometric observations should also be secured, and the polariscope should be employed to determine the proportion of polarized light in various parts of the corona.

NOVA AURIGÆ.—Prof. Barnard has recently made some measures of the position of Nova Aurigæ, with a view to detecting proper motion. The two comparison stars selected were the stars E and F in Mr. Burnham's previous list of comparison stars. The results are stated thus (*Ast. Nach.* No. 3143):—"The measures with F come out identical with Mr. Burnham's during February, but those with E seem to show some sort of motion in distance and possibly in angle. From the position of the comparison star this can hardly be due to parallax. It is possible, though, if the discrepancy is a real displacement, that it is due to orbital motion, the orbit being so situated as to show no motion with reference to F. The difference is not sufficiently great, considering the distance, to prove anything." Prof. Barnard further remarks that although the Nova presented no nebulosity at its first appearance, it has always appeared as an undoubted planetary nebula since he observed it on August 19. Estimates of magnitude in the present condition of the Nova will depend greatly upon the telescope and magnifying power employed. Since August the nucleus has become fainter, while the light as a whole has remained essentially constant.

"ASTRONOMICAL JOURNAL" PRIZES.—"A gentleman earnestly interested in the development and progress of astronomy in his native land has authorized the editor of the *Astronomical Journal* to offer two prizes, for resident citizens of the United States" (*Ast. Jour.* No. 284). The prizes will either take the form of money or of gold medals, one being of the value of two hundred dollars and the other of four hundred dollars. In the first instance the prizes will be awarded for observations tending to advance our knowledge of cometary orbits, one being for the best series of measurements of the positions of comets during the year ending March 31, 1894, and the other for the best discussion of the path of a periodic comet, with due regard to its perturbations. With regard to the first, astronomers who hope to gain the prize must frequently be at work until sunrise, as special value will be attached to observations made at inconvenient hours.

GEOGRAPHICAL NOTES.

THE name Ibea, contracted from the initials of the Imperial British East African Company to designate their territory on the east coast of Africa, has acquired a certain amount of currency, and although open to philological criticism is practically convenient. On the same principle the great Dutch possessions in the East Indies have been termed Noi (*Nederlandsch Ost Indie*), and Mr. Ravenstein has suggested a similar abbreviation for the German East African territory (*Deutsch Ost Afrika*), only he would combine the initials with a Swahili affix or suffix signifying "land," and make it either Udoa, or Doani. The cumbrousness of using many words to specify a well-defined region seems to justify a somewhat bolder coinage of new names in geography than has hitherto been customary.

THE *Mouvement Geographique* publishes a sketch map of the Stanley Falls district of the Congo, compiled from the compass-bearings of M. Page, one of the members of the disastrous Hodister expedition. Besides Stanley, Lieutenant Gleerup and Dr. Oscar Lenz are the only other authorities on this stretch of the river. Special information is given regarding the three groups of rapids which occur between Stanley Falls station and Kibonge. The cataract of Mandombe above Stanley Falls is composed of a succession of falls from six to ten feet high and numerous rapids, but local canoe-men are able to take boats through in four or five hours. Three hours of free navigation leads to the rapids of Mamanga, where the river is barred from bank to bank by a ridge of rock about twelve feet high, and followed by rapids and other smaller falls necessitating a portage. Three and a half hours of free navigation lead to Basundu, the last cataract, which canoes are able to pass in about three hours after being lightened.

THE Antarctic whaling fleet, the dispatch of which was noticed in vol. xlvi. p. 477, has been reported from the Falkland Islands. The *Balaena*, which has the most complete scientific equipment, arrived at Port Stanley at the end of November, the *Active* on December 8, the *Diana* on December 11. The fourth vessel, the *Polar Star*, was spoken off the Plate on November 16. The telegram from Monte Video reports all well, and a preliminary notice of the scientific observations will probably follow by mail.

IN a communication to the Paris Geographical Society, M. Venukoff calls attention to the fact that although the extensive Government drainage works have almost obliterated the Pinsk marshes from the valley of the Pripet, the most recent non-Russian atlases continue to represent these marshes as they were thirty years ago. Now their site is largely forest and meadow-land.

TRAVELS IN BORNEO.

MR. CHARLES HOSE'S paper on "A Journey up the Baram River to Mount Dulit and the Highlands of Borneo," read to the Royal Geographical Society on Monday evening, was a pleasant variety in the succession of African papers which has formed the staple of the Society's programme for the session.

The Baram River runs on the whole northward through eastern Sarawak, reaching the sea in 4° 37′ 15″ N. and 115° 59′ 30″ E. Its mouth is complicated by a series of sandbanks shifting with the change of the monsoons. The river is in parts very deep, and is navigated by a fleet of Government steamers. The bordering land is low and swampy or covered with jungle until Claudetown, about sixty miles from the mouth, is reached. There the ground rises, and a prosperous trading town has been established by Chinese merchants. At Long Mari, about fifty miles further up, there are great rapids which can only be passed with difficulty, and gorges of considerable depth occur at intervals further up the stream. The journey to Mount Dulit was made up the Linjar, a large tributary of the Baram. The people on the banks of this river have a peculiar custom of keeping dead bodies in their houses encased in ornamental coffins for three months before burial; and Mr. Hose gave some highly interesting particulars regarding their burial customs, their complicated subdivisions of the world of the dead, and their habit of interchanging messages with departed friends. At the head of canoe navigation the Sibop tribe hunt various species of monkeys with the blowpipe, the valuable commodity being the intestinal calculi known as Bezoar stones, which are greatly in demand by Chinese apothecaries.

The ascent of Mount Dulit was commenced on September 21, when a hut was built at the height of 2000 feet, and a path cut through the thorny scrub to 4000 feet, near which another hut was built. Several days were spent here collecting natural history specimens, many of which were species new to science; amongst the smaller quadrupeds *Hemigale hosei*, and amongst birds *Calyptomena hosei* and *Mesobucca eximius* may be mentioned. A cave some distance higher was found with wild tobacco growing at its mouth and several remarkable ferns, one with fronds 14 feet long; but except for bats and a solitary snake, the cave was untenanted. The fauna of Mount Dulit closely resembled that of Kina Balu, showing the widespread distribution in the highlands of Borneo of Himalayan forms. The flat moss-clad summit of Mount Dulit was found to be, by aneroid, 5090 feet; and there was a magnificent view of distant ranges, the position of a number of peaks in which was fixed. Some natives reported having heard a tiger roaring in the neighbourhood, but Mr. Hose found the sound to proceed from a gigantic toad, measuring 14½ inches round the body. At the close of the paper Dr. Bowdler Sharpe F.R.S., pointed out the great importance of Mr. Hose's results in their bearing on geographical distribution.

BACILLI IN BUTTER.

THE fact that milk affords a particularly suitable medium for the growth and multiplication of most micro-organisms, has rightly led to its being regarded as a dangerous vehicle for the propagation of disease. On the Continent the practice of boiling all milk before use, and so destroying any pathogenic microbes which may be present, is almost universal, and recently a number of special pieces of apparatus have been devised for household use, ensuring the efficient so-called "pasteurization" of milk. In England, however, we but rarely boil our milk in spite of outbreaks of diphtheria and typhoid fever having been not infrequently traced to a particular milk supply. In a paper by Cnopf on the bacterial contents of milk it is stated, that on one occasion out of every thirteen samples of milk supplied to Paris one was found to contain tubercle bacilli, whilst it is well known that the germs of typhoid, cholera, diphtheria, anthrax, &c., thrive readily in this medium. But although milk has been made the subject of much careful experimental investigation, comparatively little is known of the microbial condition of butter. Heim has shown that cholera bacilli purposely rubbed into butter could be demonstrated after thirty-two days, whilst typhoid bacilli similarly introduced were found after three weeks, and tubercle bacilli after the lapse of a month, although Gasperini discovered the latter in butter even after 120 days. Quite recently Lafar has published a paper, "Bacteriologische Studien über Butter" in the *Archiv für Hygiene*, in which he has recorded his investigations on the micro-organisms found in Munich butter. These experiments are instructive as exhibiting the fitness of butter to support a large number of bacteria, and thus furnish an interesting supplement to what is already known concerning the longevity of pathogenic microbes in this medium. The samples examined were prepared from fresh cream and were investigated as soon as possible after the butter was made. It was found that the number of microbes differed according as the portion for experiment was taken from the outside or from the interior of the piece of butter. Thus in one instance whilst one gram from the centre of the pat contained 2,465,555, on the outside in the same quantity as many as 47,250,000 micro-organisms were found. Taking the average of a number of examinations, it was estimated that the interior of a lump of butter possessed from 10 to 20 millions of bacteria in a single gram. Lafar is inclined to regard this as an under rather than an over-statement of the number, inasmuch as there are always probably present a certain proportion of microbes which will not develop at the ordinary temperature, or on the gelatine-peptone medium usually employed. He graphically puts it that, in some cases it is conceivable that the number of organisms swallowed with a moderately-sized slice of bread and butter may exceed that of the whole population of Europe! Lafar found that butter kept in a refrigerator, with a temperature of between 0° to + 1° C. at first (after five days) showed a marked reduction in the number of bacteria, but that no further diminution took place, although the sample was kept for a month at this temperature. Samples kept at from 12° to 15° C. exhibited a marked increase in the number of micro-organisms, a rise from 6 to 35 millions being observed in the course of nine days, whilst when placed in the incubator (35° C.) after four days the bacteria had fallen from 25 to 10 millions, and after thirty-four days only 5 per cent. of the original number present were discoverable. Experiments were also made to ascertain what was the bacterial effect of adding salt to butter kept in a refrigerator. It was found that although the numbers were thereby considerably reduced, that yet, even when as much as 10 per cent. of salt was added, the complete destruction of the bacteria was not accomplished. On examining, however, gelatine-plates prepared from these samples, it was ascertained that the organisms present consisted almost entirely of a pure cultivation of one particular microbe, which was apparently entirely unaffected by the addition of salt, and had grown and multiplied to the exclusion of nearly all the other bacteria originally present. When samples similarly salted were placed in the incubator (35° C.) the result was rather different, for whilst there was more apparent connection between the proportion of salt added and the diminution in the number of bacteria, more varieties of micro-organisms were found on the gelatine-plates. But in this case, also, the germicidal effect produced was not proportional to the increase in the amount of salt. Samples of artificial butter were also examined, and were invariably found to be much poorer in bacteria than ordinary butter. Thus, whilst the smallest number found in one gram was 747,059, in real butter considerably over two million microbes was the minimum. Two varieties of bacilli have been isolated and described, which were found very constantly present in butter throughout these investigations. They are beautifully illustrated and shown in coloured plates as individual organisms and colonies at the end of the paper. Lafar purposes continuing his investigations, and it is to be hoped that the examination of butter for pathogenic micro-organisms, about which so little is known, will form an important feature in any further researches he may undertake.

GRACE C. FRANKLAND.

THE OCCURRENCE OF NATIVE ZIRCONIA (BADDELEYITE).

THE discovery of native zirconia was first made public in my letter to NATURE (vol. xlvi. p. 620) in October last; at the same time I gave characters sufficient for the recognition of the new mineral, and suggested the name *Baddeleyite*, in honour of Mr. Joseph Baddeley who had brought the specimen with other dense minerals from Rakwana in Ceylon. As there was only a single fragment of what at first sight seemed a hopelessly imperfect crystal, the determination of all the important characters without appreciable injury of the specimen was a task of an attractive kind: the technical details of the investigation (including quantitative chemical analyses) and the line of argument by which definite results were evolved from the observations, were communicated to the Mineralogical Society at the meeting held on October 25 (NATURE, vol. xlvii. p. 70), and crystals of hydrous zirconium oxychloride prepared by identical methods from Baddeleyite and artificial zirconia, respectively, were exhibited for comparison. Having regard to the unexpected result of the chemical examination and the difference of the characters of Baddeleyite from those of artificially prepared crystals of zirconia, every care had been taken to get results as accurate as the material itself would admit of.

Of course it was hoped that the occurrence of native zirconia, once established, would soon be noticed elsewhere; and in fact, I hear this morning (January 3) from Dr. Hussak of the Geological Survey of Brazil, that flawless crystals of zirconia are actually met with in the south of São Paulo as an accessory constituent of an augitic rock described under the name of Jacupirangite by my friend Mr. O. A. Derby.

The Brazilian mineral had three or four years ago been regarded by Dr. Hussak (who had then only a small amount of material for examination) as probably orthite (silicate of cerium, iron, &c.), a mineral with which it agrees in its more obvious external characters, and it was mentioned later under that name in Mr. Derby's description of the Jacupirangite; but more recently Dr. Hussak, on isolating a score of flawless crystals from the decomposed rock, recognized the distinctness of the mineral from orthite, determined the geometrical and physical characters of the crystals, and decided from a chemical examination that the material was a tantalo-niobate of probably some member of the yttrium-cerium group: these results were published in the *Neues Jahrbuch für Mineralogie*, 1892, Band II. p. 142, immediately after my announcement of the occurrence of native zirconia in Ceylon had been sent for publication, but they had been forwarded from Brazil as early as the month of June. Dr. Hussak now informs me that the Brazilian mineral, which had been sent to Sweden for a complete quantitative examination, has been determined by Prof. Blömstrand to be almost pure zirconia.

As regards crystalline form, the parametral elements obtained by myself for Baddeleyite, and announced at the meeting of October 25, agree in a very satisfactory way with those determined by Dr. Hussak for the Brazilian mineral, while as regards optical characters, the two descriptions are practically identical. The only important deviation of external character is in the specific gravity; that of Baddeleyite is 6·025, that of selected crystals of the Brazilian mineral is 5·006.

Now it seems almost impossible that the specific gravity of crystals of a simple oxide presenting otherwise identical characters can vary to this extent, and the explanation of all the difficulty will probably be found to be that Dr. Hussak's specimens really belong to two distinct minerals; that while the crystalline form and optical characters were determined from the one (zirconia), the specific gravity and the chemical composition were originally determined from the other (yttrium tantalate). In fact, it was stated in my former communication that the Baddeleyite of Ceylon is itself associated with such a chemical compound; and I may add that this associated mineral was there designated without the mention of a species-name because it had been found to have a specific gravity (4·9) far below the inferior limit (5·5) hitherto observed in the case of undoubted Yttrotantalite: it was intended to determine later whether or not the lowness of the specific gravity was accompanied by a difference in the proportion of the chemical constituents; further, the similarity of aspect of the zirconia and yttrium tantalate of Ceylon is such that a confusion of the two would be easy. In this way the discrepancy of the chemical results and the complete accuracy of the observations of Dr. Hussak, whose reputation stands so high in the annals of mineralogical science, would be found consistent with each other.

There remains the inconvenience that two names have been suggested for the same mineral; but according to the rules of nomenclature formulated by Dana (rule 13*d*) the name of *Baddeleyite* has the prior claim. I may add that the name *Brazilite* was in use eight years ago, commercially at least, for the specification of an oil-bearing rock found in the neighbourhood of Bahia. L. FLETCHER.

GAS POWER FOR ELECTRIC LIGHTING.

AT the ordinary meeting of the Institution of Civil Engineers on Tuesday, January 10, an interesting paper on "Gas-Power for Electric Lighting" was read by Mr. J. Emerson Dowson. The author stated that in Great Britain alone gas-engines had been sold for electric lighting, exceeding in the aggregate 7000 horse-power, and that in Germany engines were used for about 1100 arc- and 90,000 glow-lamps. It was, however, only within the last few years that gas-engines of large size had been before the world in a practical form. The varying load-factor in central stations was a serious trouble, and the author hoped to show that much of the present loss, due to fuel, water, and wages, would be avoided if gas-power were used instead of steam-power.

Special reference was made to the central-station at Dessau, belonging to the German Continental Gas Company. That station was opened in 1886 with two 60 horse-power, one 30 horse-power, and one 8 horse-power (effective) engines, worked with town-gas, and all the dynamos were driven by belting and counter-shafts. In 1891 considerable alterations were made. One 60 horse-power engine, with its belting and counter-shaft, was retained, and one of 120 horse-power introduced, coupled direct to its dynamo. The speed of the engine and coupled dynamo was 145 revolutions per minute, and the consumption of town-gas was equal to 39 cubic feet per kilowatt. Formerly, without accumulators, it was thought necessary to adjust the size of the engines to the supply, so that they should always be worked to their full extent. It had, however, been found that a limited supply could more advantageously be furnished entirely from accumulators. In spite of the loss of about 21 per cent. in the accumulators, large engines worked more profitably in parallel than smaller ones supplying direct without accumulators. Since February, 1889, the Municipality of Schwabing, a suburb of Munich, had used an Otto engine worked with Dowson gas for 10 arc- and 300 glow-lamps. The load was variable, but with an average output of 22·5 kilowatts per hour the fuel-consumption was 3·3 lbs. per kilowatt. The town of Morecambe was lighted by nine arc-lamps and glow-lamps, equal to 1600 of eight candle-power each, the dynamos being driven by Stockport gas-engines worked with Dowson gas. With an output of only 1155 kilowatts per week the consumption of fuel was 2·58 lbs., and the cost of the gas, including wages and fuel, was ½d. per kilowatt delivered. At the château of Mr. Say, at Longpont, in the South of France, there were 650 glow-lamps and one arc-lamp, supplied by a dynamo driven by a Crossley engine worked with Dowson gas. The consumption of fuel was 1·2 lb. per indicated horse-power, and 2·7 lbs. per kilowatt per hour.

It was believed that the late Sir William Siemens first drew attention to the fact, that when illuminating-gas was burnt in a gas-engine to drive a dynamo, much more light was produced electrically than could be produced by burning the same quantity of gas in burners in the usual way. Latterly the consumption of gas per horse power in gas-engines had been reduced, and the ratio was at the present time about 20 to 1 in favour of converting the gas into an arc-light, by means of a gas-engine. The author had collected data from various sources, as to the consumption of ordinary town-gas by engines supplying electric light with and without accumulators. The average of all the returns, with engines under varying loads and without accumulators, was about 47 cubic feet per kilowatt-hour; when accumulators were used, the consumption of gas was less, because the engines then worked under a full load. With 47 cubic feet per kilowatt, and 55 watts per 16 candle-power, one light of that power required only 2·6 cubic feet per hour; whereas a standard Argand burner required 5 cubic feet per hour. In this comparison, it was assumed that the glow-lamps and gas-burners were in good order, but under ordinary working conditions they did not maintain so high a duty.

The question of load-factor was a serious one with any type of engine, but with gas-engines the loss was much less than with steam-engines. When a gas-engine was stopped, its consumption of fuel stopped also, and there was no furnace to maintain, nor was there any water to boil at starting. At the same time, it was desirable that the gas-engine should be worked as much as possible under a full load, and in this respect the experience at Dessau was generally confirmed. A central-station was worked under trying conditions, and in the London district there was only a full output of current during from three to five hours in every twenty-four; moreover, about 60 per cent. of the total output was required during that short period. In practice, this meant that in a station where the current was supplied without accumulators, the engines were run at a reduced speed during a portion of the time, and at other times some of them were stopped altogether; but all had to be ready to work in the evening, and occasionally in the day-time, when there was fog. Generally, it might be assumed that the average consumption was more than 6 pounds per kilowatt where accumulators were used, and about 9 to 12 pounds where they were not used. In any case, with the best possible arrangement of steam-power, there must be a large amount of fuel consumed which did no useful work; for, even if some of the fires were drawn, they had to be re-lighted, and the large quantity of water which had cooled during the time of standing must be re-heated.

The author believed that the solution of the difficulty was to be found in the use of gas-plant instead of steam-plant. With a large gas-engine, one brake horse-power per hour could be obtained with a consumption of about 1 lb. of anthracite, or 1⅓ lb. of coke; whereas the consumption of coal with the steam-engines used for central-stations, must be taken at about 2½ lbs. per brake horse-power, when working under a full load. A saving of not less than 50 per cent. could therefore be effected in stations where the engines were fully loaded; and where there were great fluctuations in the output, the loss of fuel with boilers not used, or only partly used, could be almost entirely avoided. For a maximum of 400 kilowatts, there would be three gas-generators, each capable of supplying one-third of the maximum required. The production of gas could be raised or lowered in several ways, and the working of each generator could be stopped immediately by shutting off its steam supply. Supposing, therefore, that all three generators were working at their maximum rate, and a gradual reduction was required, this could easily be effected; and when the production of one or two generators could be dispensed with their operation was at once stopped. The third generator could then be kept at work, and its production adjusted to suit the minimum consumption required. A gas-generator had a small grate-area compared with that of a boiler, and much less cooling-surface; it contained no water, and required no chimney-draught. A generator of the size referred to lost only 6 to 8 lbs. per hour whilst standing. If an average of only 40 per cent. of the maximum power were required for twenty-one hours, it was equivalent to letting two of the generators stand for that period; and at 8 lbs. each per hour that meant a total loss of only 3 cwts.; compared with the much greater waste when steam-power was used. As the use of large engines, driven with generator gas, was of recent date, the author proceeded to describe the gas-plant used, and gave the results of engines working regularly with Dowson gas, under the usual conditions obtaining in factories. He also gave the results of brake-tests made with several engines of large size, and reproduced indicator diagrams taken from engines of different makers. Although admirable results had undoubtedly been obtained from engines working with the Otto cycle, he was of opinion, that, with engines of large size, the results would be still better if the cycle were altered, especially when generator-gas was used. His reasons for this were fully stated in the paper.

The following was a summary of the points urged by the author:—

1.—When town-gas was used for driving the engines of an electrical station, the consumption was about 50 per cent. less than the volume of gas required to give the same amount of light by ordinary burners.

2.—When town-gas was used, neither boiler nor firemen were required, and there were no ashes to remove; less space was needed; no accumulators were required, except such as might be necessary to equalize the load of the engines and to provide for a small amount of storage. The engines could be worked in the most crowded districts, close to where the lights were required, and where boilers were not allowed.

3.—When generator-gas was used, the consumption of fuel under a full load would be at least 50 per cent. less than with steam-power, and the loss due to steam-boilers not being fully worked could be almost entirely avoided.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—We regret to hear that Professor Cayley has been suffering from serious illness, and that he is in consequence unable to give this term his advertised course of lectures in Pure Mathematics.

L. Cobbett, M.A., M.B., of Trinity College, has been appointed Demonstrator of Pathology in the place of Dr. E. Lloyd Jones, who has resigned the office.

Mr. F. Darwin, Deputy Professor of Botany, announces a special course of lectures in the Chemical Physiology of Plants, to be given by Mr. Acton, of St. John's College, on Tuesdays in the present Lent Term.

Mr. J. Y. Buchanan, F.R.S., announces a second course of lectures in Geography, to be given in the Easter Term.

Mr. A. E. Shipley has been appointed an additional member of the Special Board for Biology and Geology.

SCIENTIFIC SERIALS.

Journal of the Royal Agricultural Society of England, 3rd series, vol. iii. pt. 4.—Cottage sanitation (illustrated), by H. McLean Wilson, a paper prepared under the supervision of Dr. Spottiswoode Cameron and T. Pridgin Teale, F.R.S. It contains a discussion of the principal sanitary defects, which are most likely to be found in the houses of agricultural labourers, with valuable suggestions and remedies. The object aimed at is "to put the whole country, and every house in the country, into such a condition that if the epidemic (cholera) should break out it would have no chance of spreading."—Field experiments on the fixation of free nitrogen, by James Mason, gives an account of the enriching of some plots of poor land on the Oxford clay at Eynsham by the growth of two leguminous crops in succession. The two crops chosen were beans and mixed clovers. So far as they go the results are striking. Prior to 1888 the land had never been cultivated or received any manure. Brought into tillage in that year two plots produced 10½ cwts. and 9 cwts. per acre of barley and oats respectively, straw included,—an excessively low return. In the autumn of 1888 the plots were treated with 20 cwts. of basic slag per acre, and the subsoil with the same amount. Beans in the following year yielded an average of 46 bushels and 23 cwts. straw per acre. In 1890 mixed clovers gave a yield of 28 cwts. per acre as the average of the two plots, and in 1891 a crop of three tons clover-hay was obtained. Potatoes were grown upon the plots last year, and gave an average yield of eight tons per acre. Excepting the basic slag, no manure of any kind had ever been applied to the plots. The experiments are being continued and extended.—Wild birds, useful and injurious (illustrated), by C. F. Archibald.—Utilization of straw as food for stock, by Joseph Darby. Showing methods of using chaffed straw as a remedy for the deficient hay crop of last summer, with records of previous experiences under similar circumstances.—Yew poisoning, by Mr. E. P. Squarey, Mr. Charles Whitehead, Mr. W. Carruthers, F.R.S., and Dr. Munro. But few definite conclusions can be arrived at, owing to the conflicting nature of the information available. It appears, however, (1) that both the male and female yews are poisonous; (2) the poisonous alkaloid (or alkaloids) exists chiefly in the leaves and in the seeds; (3) the fleshy part of the fruit is harmless, or nearly so; (4) the amount of poisonous alkaloid in the leaves varies considerably with individual trees, and perhaps with the season of the year. Dr. Munro contributes a review of the chemical work done upon taxine, the only alkaloid in yew which has been investigated; very little is known with certainty about it, either as to its chemical nature or its physiological action. As Dr. Munro suggests, "yew leaves merit *exhaustive* chemical examination."—Besides the official reports, there are several short articles, including one upon the ferments of milk, abridged by Dr. Munro from Prof. H. W. Conn's pamphlet on the subject, issued last summer; also a paper upon the decline of wheat-growing in England, by the editor.

American Journal of Science, January.—The age of the earth, by Clarence King. This paper contains an application of Lord Kelvin's reasoning from probable rates of refrigeration to the determination of the earth's age, aided by Dr. Carl Barus's recent work in geological physics, especially his determination of the latent heat of fusion, specific heats melted and solid, and the volume expansion between the melted and solid state, of the rock diabase. Thermal considerations have shown that with a given initial excess of temperature of the earth over surrounding space, and an assigned value for rock conductivity, it is possible to determine the curve of temperature from the earth's centre to its surface. It appears that for an initial temperature of 2000° C., the initial maximum temperature must still extend uniformly from the centre to within a few hundred miles of the surface for any admissible value of the age. But since the pressures increase steadily as we proceed towards the centre, there must be a point at which their effect outweighs that of the temperature, and the material, though very hot, remains in the solid state. Now on the data supplied by Barus's researches it is possible to state what temperatures are necessary to keep a certain representative species of rock in the fluid state at successive points within the earth. The amount of possible liquid layer is limited by the facts of tidal rigidity, which fix the maximum admissible temperature at 1950° and the age at 24×10^6 years. Lower values are excluded by the gradient of temperature observed on proceeding downwards from the surface. This value, twenty-four million years, agrees fairly well with the age assigned by Helmholtz and Kelvin to the sun. It is also concluded that the earth never was all liquid, that the original liquid layer did not exceed 53 miles, and that the spheroidal shape is due to the plasticity of the lithosphere as manifested under the action of very slowly applied forces.—Tertiary geology of Calvert Cliffs, Maryland, by Gilbert D. Harris.—"Anglesite" associated with boleite, by F. A. Genth.—Preliminary account of the iced-bar base apparatus of the United States Coast and Geodetic Survey, by R. S. Woodward.—Some experiments with an artificial geyser, by J. C. Graham.—Observations of the Andromed meteors of November 23 and 27, 1892, by H. A. Newton.—Preliminary notice of a meteoric stone seen to fall at Bath, South Dakota, by A. E. Foote.—New Cretaceous bird allied to Hesperornis, by O. C. Marsh.—Skull and brain of Claosaurus, by O. C. Marsh.

THE *Botanical Gazette* for October contains an interesting article by Mr. H. L. Russell on the bacterial investigation of the sea and its floor. The author has had the opportunity of carrying on bacteriological observations in sea-water, both from the Bay of Naples and from the coast of Massachusetts. He finds micro-organisms invariably present in sea water, though not in such large numbers as in fresh water, even at a great distance from the shore, and to a depth of 3200 feet; and a larger number in the slime at the bottom than in the water itself. Some marine forms are cosmopolitan, and the bacteria that are so universally present in sea-water and mud seem to be quite peculiar to this habitat.—Mr. E. L. Berthoud describes the mode in which the geographical distribution of some plants has been greatly extended by the agency of the buffalo.—In the number for November Prof. Underwood gives a report of the proceedings of the International Botanical Congress lately held at Genoa.—Mr. G. W. Martin contributes an account of the development of the flower and embryo-sac in *Solidago* and *Aster*.

Bulletin of the New York Mathematical Society, vol. ii. No. 2, November 1892.—This number practically consists of one paper, and that a very interesting one, by Dr. Emory McClintock, "On the Non-Euclidian Geometry," a subject which has been more than once brought before our readers. In vol. viii. (1873) appeared Clifford's translation of Riemann's Habilitationsschrift "ueber die Hypothesen welche der Geometrie zu Grunde liegen" (1854). In 1883 this geometry was considered in Cayley's British Association address, and quite recently (February 25, 1892) in a translation of Poincaré's "Revue Generale des Sciences." "The chief lesson to be obtained from all non-euclidian diversions is that the distinguishing mark of euclidian geometry is fixity of distance-measurement, by which alone it is possible to draw the same figure upon different scales. That the same figure may be drawn upon different scales might well be laid down as the axiom necessary and sufficient to distinguish euclidian from non-euclidian geometry." To this is appended a footnote which says that this is "referred to as 'the axiom of similars' by Sir *Richard* (sic) Ball in the article 'Measurement' of the "Encycl. Brit." A short article follows on the new logarithmic tables of J. de Mendizábal-Tamborrel (Paris, Hermann, 1891). In addition there are the usual "Notes," but no list of publications.

No. 3, December 1892.—This number contains a careful criticism of Ball's "Mathematical Recreations," with suggestions and discussions by Prof J. E. Oliver of Ithaca, New York, and an account of Dr. Julius Bauschinger's "Zweites Münchener Sternverzeichniss, enthaltend die mittleren Oerter von 18,200 Sternen für das Aequinoctium, 1880," by Prof. T. H. Safford. "Notes" and "New Publications" follow.

Wiedemann's Annalen der Physik und Chemie, No. 12.—On the temperature coefficient of the electrical resistance of mercury and on the mercury resistances of the Imperial Institution, by D. Kreichgauer and W. Jaeger. The coefficient was measured in the case of the copies of standard resistances already described. The formula obtained for the resistance w_t at temperature t by two independent methods was

$$w_t = w_o \ (1 + 0{\cdot}000875t + 0{\cdot}00000125t^2)$$

—Generation of electricity by friction of gases against metals, by K. Wesendonck.—On galvanic polarization at small electrodes, by F. Richarz.—Electric oscillations in wires, direct measurement of the moving wave, by Kr. Birkeland. The oscillations were produced in two copper wires running parallel to each other at a distance of 80cm. They were 30m. long, and ended in one direction in brass plates 40cm. square, facing two similar plates connected with the terminals of the spark gap of a powerful induction coil. The potentials along the wire when the coil was working were determined by measuring the length of the sparks crossing between the knobs of a spark micrometer, one of them being connected with the wire by a sliding contact, the other leading through a telephone to earth. Statical effects on the telephone were made inappreciable by laying a thread moistened with dilute sulphuric acid across the wires near the "collector" plates. Under these circumstances the passage of sparks was immediately indicated by the telephone, and their length could be measured down to 0·0005mm.—Determination of dielectric constants by means of the differential inductor, by Oscar Werner.—Measurement of resistances by means of the telephone, by Max Wien.—Diffusion of light by rough surfaces, by Christian Wiener. Experiments made on cast gypsum show that Lambert's law of diffusion, according to which the brightness of a surface is independent of the angle from which it is seen, is not strictly correct. The brightness at the edge of a round surface is 0·6 times that given by his law. In the vicinity of reflection points the brightness is greater, and at the greatest brightness the angle of incidence is greater than the angle of reflection.—A unit for measuring intensity of sensation, by the same.—On internal friction of solid bodies, especially metals, by W. Voigt.—Measurement of the coefficient of diffusion of liquids, by F. Niemoeller.—Absolute compressibility of mercury, by G. de Metz.—Propagation of energy through the ether, by G. Helm.—On the utilization and action of the telephone in electrical null methods; reply to Hr. Winkelmann, by E. Cohn.—On the solution of sodium silicates, and influence of time upon their constitution, by F. Kohlrausch.—Behaviour of polarized light in refraction, by G. Quincke.—On a mercury arc light, by L. Arons.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Meteorological Society, December 21.—C. Theodore Williams, President, in the chair.—The following papers were read:—Moving anticyclones in the Southern Hemisphere, by Mr. H. C. Russell, F.R.S., Government Astronomer, New South Wales. The author describes the results of his practical study of the daily weather charts for Australasia, and states that the leading fact brought out is that the weather south of 20° S. latitude is the product of a series of rapidly moving anticyclones, which follow one another with remarkable regularity, and are the great controlling force in determining local weather. These anticyclones are more numerous in summer than in winter, the average number for the year being 42. They usually take seven or eight days to travel across Australia in summer, and nine or ten days in winter; the average daily rate of translation being 400 miles. The shape of the anticyclone appears to undergo some modification as it nears the east coast. The winds on the north side of the anti-cyclone are not so strong as those on the south side, and the intensity of the weather is in proportion to the difference in pressure between the anticyclone and the V-depression, but the relation of the pressures varies frequently before the wind responds, the pressure appearing to be controlled from above by the more or less rapid descent of air which feeds the anticyclone. Cyclonic storms are very unusual, and do not occur more than once in two or three months.—The tracks of ocean wind systems in transit over Australasia, by Capt. M. W. C. Hepworth. The author has examined the daily weather charts of Australia and New Zealand, and has prepared maps showing the daily positions of the centres of high and low pressures for a whole year. He finds that the wind systems, which make their first appearance to the westward and south-westward, advance to the eastward rapidly, and frequently very rapidly, during the winter months, but during the summer months they usually move more slowly, and not unfrequently recurve. Their progress is retarded by contact with the areas of high pressure which they encounter; the mean of the tracks of these anticyclones, moving also from west to east, appears to be across the southern portion of Australia and onward, crossing the islands of New Zealand during the winter months, but to the southward of Western and South Australia, across Victoria and New South Wales, and thence to the north-eastward, avoiding New Zealand during the summer months.—Rainfall of Nottinghamshire, 1861–90, by Mr. H. Mellish. The author has collected and discussed all the rainfall records made in the county during the thirty years, and finds that in the extreme west the mean rainfall is 27 inches or more, and that over the rest of the county it varies between 25 and 27 inches, except north of the Manchester, Sheffield and Lincolnshire Railway, where the rainfall is less than 25 inches, and in the north-east towards Gainsborough, where it is not more than 23 inches. The year of greatest rainfall was 1872, and of least rainfall 1887. October is the wettest month and February the driest.—A new instrument for cloud measurements, by Dr. Nils Ekholm.

Geological Society, December 21, 1892.—Prof. J. W. Judd, F.R.S., Vice-President, in the chair.—The following communications were read:—On a Sauropodous Dinosaurian vertebra from the Wealden of Hastings, by R. Lydekker. In addition to *Hoplosaurus armatus* and *Pelerosaurus Conybearei*, there is evidence of another large Sauropodous Dinosaur in the Wealden, now known as *Morosaurus brevis*. Up to the present time it has been impossible adequately to compare *Hoplosaurus armatus* with *Morosaurus brevis*; but recently Mr. Rufford has sent to the British Museum an imperfect dorsal vertebra of a large Sauropodous Dinosaur from the Wealden of Hastings, which enabled the required comparison to be made. The author describes the vertebra, contrasts it with that of *Hoplosaurus armatus*, and gives presumptive evidence that it should be referred to the so-called *Morosaurus Becklesi* (Marsh), which apparently cannot be separated from *M.* (*Cetiosaurus*) *brevis*. He has not been able to compare Mr. Rufford's specimen with the dorsals of the American *Morosaurus*, in order to discover whether the English Dinosaur is correctly referred to that genus. This paper led to a discussion, in which the chairman, Mr. Hulke, Prof. Seeley, Mr. E. T. Newton, and the author took part.—On some additional remains of Cestraciont and other fishes in the Green Gritty Marls, immediately overlying the Red Marls of the Upper Keuper in Warwickshire, by the Rev. P.

B. Brodie. The vertebrate remains occur in a very thin band of marly friable sandstone lying between two beds of green marl, though in some places the same bed has itself no admixture of sandy material. Bones and teeth are so numerous that it might almost be called a bone-bed. It does not exceed three inches in thickness. It contains ichthyodorulites of Cestraciont fishes, abundant palatal teeth of *Acrodus keuperinus*, ganoid fish-scales, and abundant broken bones, some of which may belong to fishes, others to labyrinthodonts, and amongst the latter a fragment of a cranial bone. The Chairman congratulated the Society on the presence of one of its Fellows who had been connected with it for nearly sixty years, and had read his first paper almost half a century ago. He hoped that the Society would still continue to receive communications from the same source of like interest and value. Mr. J. W. Davis, Mr. H. B. Woodward, and Mr. E. T. Newton also spoke.—*Calamostachys Binneyana*, Schimp, by Thomas Hick. Communicated by J. W. Davis.—Notes on some Pennsylvanian calamities, by W. S. Gresley. — Scandinavian Boulders at Cromer, by Herr Victor Madsen, of the Danish Geological Survey. Communicated by J. W. Hulke, F.R.S. During a visit to Cromer in 1891 the author devoted much attention to a search for Scandinavian boulders, and obtained three specimens; one (a violet felspar-porphyry) was from the shore, and the other two were from the collection of Mr. Savin. The first was considered to come from south-east Norway, and indeed Mr. K. O. Björlykke, to whom it was submitted, refers it to the environs of Christiania. The author considered that the two specimens presented to him by Mr. Savin, who had taken them out of Boulder Clay between Cromer and Overstrand, were from Dalecarlia; and these were submitted to Mr. E. Svedmark, who compared one of them (a brown felspar-hornblende-porphyry) with the Grönklitt porphyry in the parish of Orsa, and declared that the other (a blackish felsite-porphyry) might also be from Dalecarlia. This paper was discussed by Mr. C. Reid, Mr. J. W. Davis, the Rev. P. B. Brodie, Dr. Hicks, Mr. Marr, and the Chairman.

EDINBURGH.

Royal Society, December 19, 1892.—Sir Douglas Maclagan, President, in the chair.—Dr. Hunter Stewart read a paper on an extension of Kjeldahl's method of organic analysis, and described an apparatus which he had devised for the estimation of the amount of organic carbon present in water.—Prof. Rutherford read a note by Dr. W. G. Aitchison Robertson on the madder-staining of dentine. Rabbits were fed on madder for some time and were then killed, the dentine being then found to be stained. When other food was supplied for a time, the process of feeding on madder being resumed afterwards, two coloured layers were found in the dentine, with an intermediate colourless layer.—Prof. C. G. Knott read a paper on recent innovations in vector theory. He entered into a critical examination of the anti-quaternionic attitudes taken up by Prof. Willard Gibbs, Mr. Oliver Heaviside, Prof. Macfarlane, and others. His chief arguments were (1) that the quaternion was as fundamental a geometric conception as either its scalar or its vector part—indeed more fundamental; (2) that in the development of his dyadic notation, Prof. Gibbs, being forced to bring the quaternion in, logically condemned his own position; (3) that a really flexible vector analysis must be versorial, the equations $ij = k$, $jk = i$, $ki = j$, &c., being from the geometrical and physical point of view essentially rotational; (4) that the non-associative character of the vector-analysis, in which i^2, j^2, k^3, were *assumed* to be $+ 1$, rendered it totally unfit for higher physical research; (5) that this tinkering with the algebraic sign quite spoiled the real efficiency of the very beautiful quaternion operator ∇—Prof. Gibbs, for example, being compelled to introduce the (supposed) new functions of operation Pot, New, Lap, Max, which in quaternions are the very simplest of inverse functions of ∇, and are best expressed as such.

DUBLIN.

Royal Dublin Society, December 21, 1892.—Prof. A. C. Haddon in the chair.—Prof. Sollas, F.R.S., read a paper on pitchstone and andesite from tertiary dykes in Donegal. The author found that a microscopical examination of some remarkably fresh glassy rocks from Donegal revealed a close resemblance between them and rocks of the same age in Arran. This helps to confirm the supposed great extension of tertiary dykes through the north-west of Ireland. Prof. Sollas next read a paper on the variolite and associated igneous rocks of Roundwood, co. Wicklow. He described them as a complex of basic rocks, including altered ophitic dolerite, spilite (variolite du Drac), and spherulitic tachylite (variolite de la Durance). In connection with the epidotisation of the rock the author pointed to the excessive fissuring which it has undergone; and showed that the formation of epidote is attended with considerable diminution of volume, sufficient to account for the cracks. The formation of serpentine and chlorite is attended with expansion, and chlorite can scarcely be formed without the simultaneous liberation of a disproportionately large percentage of quartz. This explains the common association of chlorite with the quartz of quartz veins.—Sir Howard Grubb, F.R.S., described a new system of mounting for monster reflecting telescopes.—Mr. H. H. Dixon read a paper on the germination of seedlings in the absence of bacteria. Seeds, the outer coats of which were sterilized, germinated in the absence of bacteria, and being kept absolutely free from bacteria did not, after growth had ceased, suffer the decay of death, but remained for more than twenty months apparently unchanged. An apparatus for sterilising the outer coats of the seeds and sowing them without the introduction of bacteria was also described.—A paper was communicated by Prof. A. C. Haddon, and Miss A. M. Shackleton, describing some new species of Actiniæ from Torres Straits.

BERLIN.

Meteorological Society, December 6.—Dr. Vettin, President, in the chair.—Prof. Assmann gave a detailed description of the meteorographs set up in the "Urania-pillars." Each pillar contains a thermograph, a barograph, and a hygrograph, placed side by side in a metal case through which a rapid current of air is kept up. The thermograph consists of a Bourdon spring, filled with alcohol, whose movements are communicated to an external recording-lever. The barograph is made of four boxes joined together, and delicately balanced by a weight, whose movements are similarly recorded externally. The hygrograph consists of a bundle of hairs 2 m. in length. The above instruments have continued to work well after several months' use. Their chief defect is due to the hygroscopic properties of the paper on which the three levers trace their record. The large amount of material in the shape of meteorograms already collected has revealed a number of interesting facts. Thus, for instance, the temperatures recorded on two closely-adjacent pillars may differ by 1° or more not only on a warm summer day, but also during the night of November 26, the coldest of this year. In one case the air was found to be warmed by the adjacent row of houses exposed to direct sunlight. In another the radiation was observed to be greater opposite a gateway than in the street. The very considerable local differences of air-temperature recorded on closely-neighbouring pillars could scarcely have been *à priori* expected.

Physiological Society, December 9, 1892.—Prof. du Bois Reymond, President, in the chair.—Prof. Exner, of Vienna, gave a *résumé* of his researches on the innervation of the crico-thyroid muscle in rabbits and dogs. In each he had found a branch from the pharyngeal branch of the vagus distributed to this muscle, together with the superior laryngeal nerve, to which he has given the name of median laryngeal nerve. The communication was illustrated by an experimental demonstration.—Dr. Hansemann stated that he had obtained photographs of microscopic objects, which when placed in a stereoscope, presented an appearance of solidity. They were produced by taking one photograph of the object in focus for a given level, and then a second photograph at a different level. These photographs united stereoscopically gave the impression of solidity.—Prof. Hilgard drew attention to the remarkable fact that the most civilized races of antiquity usually established themselves in dry districts. This he attributed to the fact, borne out by numerous analyses of soils in America, that in dry regions the earth is far richer in mineral food-stuffs necessary to plant life than in wet regions where these are largely washed out of the soil. Hence in dry regions simple irrigation suffices to produce a luxuriant vegetable growth, while on the other hand the soil of moist regions is very rapidly exhausted.

PARIS.

Academy of Sciences, January 9.—M. de Lacaze-Duthiers in the chair.—Drainage waters of cultivated lands, by M. P. P. Dehérain. An experimental investigation of the substances found in water drained from various cultivations showed that all the waters contained a fair proportion of nitrates. Even beetroot, which not only utilizes nitrogen for the formation of its albuminoids, but also stores nitrates in its tissues, gave 31, 39, and 95 gr. of nitric acid per cubic metre of drainage water. Beetroot gives, however, the least quantity of nitrogen in the drained water in proportion to the crop. Next comes Turkey corn, and then potatoes. It appears certain that all nitrogen which enters the soil is either assimilated or else lost. In the case of a bad harvest there is a loss both from the poverty of the crop and the impoverished state of the soil.—On the small planets and nebulæ discovered at the Nice Observatory by MM. Charlois and Javelle, and at the Mounier observing station, by M. Perrotin. A list of eight minor planets discovered by the photographic method in four weeks, *i.e.* one-sixteenth of the time necessary to achieve the same result by eye observation.—Dilatation and compressibility of water, by E. H. Amagat. Tables are given showing the relative volumes of a quantity of water at pressures varying from 1 to 3000 atmospheres and temperatures ranging from 0° to 198°; and others showing the compressibility of water under the same conditions. This is seen to vary inversely as the pressure, and also inversely as the temperature up to very high pressures, when it begins to increase with the temperature.—Observations of Brooks's comet (November 19, 1892), made at the Paris Observatory (west equatorial), by M. O. Callandreau.—Observations of solar phenomena, made at the observatory of the Roman College during the third quarter of 1892, by M. P. Tacchini.—On the reduction of elliptic integrals, by M. J. C. Kluyver.—On the thermal variation of the electric resistance of mercury, by M. Ch. Ed. Guillaume. Pointing out the remarkable agreement of his results with those obtained by Messrs. Kreichgauer and Jäger, at the Physico-Technical Institute of Germany (see *Wiedemann's Annalen*, No. 12).—On the measurement of power in multiphase currents, by M. Blondel.—Absolute value of the magnetic elements on January 1, 1893. The elements for that date, determined at the magnetic observatory of the Parc Saint-Maur, situated in long. 0° 9′ 23″ E. and lat. 48° 48′ 34″ N., are the following:—

	Absolute values on January 1, 1893.	Secular variation in 1892.
Declination	15° 24′·3 ...	− 6′·4
Inclination	65 8·5 ...	− 0·5
Horizontal force ...	0·19596 ...	+ 0·00016
Vertical force ...	0·42297 ...	+ 0·00019
Total force	0·46616 ...	+ 0·00024

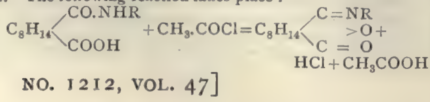
The values for the magnetic and meteorological observatory of Perpignan, long. 0° 32′ 45″ E., lat. 42° 42′ 8″ N., are

	Absolute values on January 1, 1893.	Secular variation in 1892.
Declination	14° 12′·9 ...	− 5′·9
Inclination	60 13·3 ...	− 1·8
Horizontal force ...	0·22278 ...	+ 0·00030
Vertical force	0·38933 ...	+ 0·00003
Total force	0·44856 ...	+ 0·00017

—On the purification of arsenical zinc, by M. H. Lescoeur. Zinc destined for toxicological operations can be obtained free from arsenic, antimony, sulphur, and phosphorus by two successive operations, viz. oxidation by means of nitre, and fusion with chloride of zinc.—Combinations of quinoleine with the halogen salts of silver, by M. Raoul Varet.—Symmetric dipropylurea and dipropylsulphourea, by M. F. Chancel.—On a substance derived from chloral, or chloralose, and its physiological and therapeutic effects, by MM. Hanriot and Ch. Richet.—On phagocytosis observed on the living animal, in the branchii of the lamellibranch molluscs, by M. de Bruyne.—New observations on the affinities of the different groups of gasteropods, by M. E. L. Bouvier.—On an anomaly recently presented by the secular variation of the magnetic needle, by M. Léon Descroix.—Influence of motion on the development of fowls' eggs, by M. A. Marcacci.

Amsterdam.

Royal Academy of Sciences, December 24, 1892.—Prof. Van de Sande Bakhuysen in the chair.—In a paper read by MM. S. Hoogewerff and W. A. van Dorp, some isoimides of camphoric acid were described. These were obtained by the action of $POCl_3$ or $CH_3.COCl$ on some substituted camphoramic acids. The following reaction takes place:—



$$C_8H_{14}\left\langle\begin{array}{l}CO.NHR\\ COOH\end{array}\right. + CH_3.COCl = C_8H_{14}\left\langle\begin{array}{l}C=NR\\ \qquad >O\\ C\;=\;O\end{array}\right. + HCl + CH_3COOH$$

where R is put for CH_3, C_2H_5 or C_7H_7. The isoimides are very unstable; they easily add one molecule of water, re-generating the acids from which they derive. By the action of heat they are transformed into the ordinary imides $C_8H_{14}\begin{array}{l}-CO\\ -CO\end{array}\!\!>NR$.—The same authors called attention to the fact that it seems to be a general reaction of the anhydrides of bibasic acids to dissolve in the aqueous solutions of ammonia and the primary amines, forming the corresponding acid amides: $R\left\langle\begin{array}{l}CO\\ CO\end{array}\right\rangle O + NH_2.R_1 = R\left\langle\begin{array}{l}CO.NHR_1\\ COOH\end{array}\right.$.—Mr. Bakhuis Roozeboom dealt with the solubility-curve for systems of two bodies. The general form of such a curve in its totality, as yet not known even by the researches of Engel, has been encountered by the author and Mr. Schreinemakers in studying the solubility of $Fe_2Cl_6.12H_2O$ in solutions of HCl. The curve is a continuous one, combining the two solubilities of the hydrate, recently made known by the author. It presents a summit when the proportion of Fe_2Clf is the same as in the solid hydrate. Part of the solutions give on water-additions a deposit of the hydrate, part of them give redissolution. The general form of the curve for double salts would be represented in its totality by a closed curve, surrounding the point, indicating the composition of the double salt. With this form the same division of the solutions in regard to their behaviour on water-addition is possible as above.—Prof. Lorentz treated of Stokes's theory of the aberration of light. The hypothesis of M. Stokes, that the movement of the ether admits of a velocity-potential, is in contradiction with the supposition that, at the surface of the earth, the velocity of the ether is equal to that of the planet. It might, however, be doubted whether, in M. Stokes's explanation, the first hypothesis is really necessary. In the present note it is shown that it cannot be avoided.

MODERN ADVANCED ANALYSIS.

Theory of Numbers. By G. B. Mathews, M.A. Part I. (Cambridge: Deighton, Bell and Co., 1892.)

THE book under review is a great contrast in many ways to the "Théorie des Nombres" of M. Edouard Lucas, the first volume of which has recently appeared under the ægis of Messrs. Gauthier-Villars. The latter, reminding the reader much of the same author's "Récréations Mathématiques," exhales human interest from well-nigh every page. The former is on severe philosophical lines, and may be greeted as the first work of the kind in the English language. That this should be a fact is somewhat remarkable. When the late Prof. H. J. S. Smith died prematurely many years ago he left his fellow-countrymen a very valuable legacy. Fortunately he had been commissioned by the British Association to frame a report on the then present state of the Theory of Numbers, a subject with which he was pre-eminently familiar, and in which his own original researches had won for him a great and world-wide renown. The pages of the reports for the years 1864–66 inclusive yield as a consequence a delightful account of modern research in this recondite subject. It is, however, much more than a recital of victories achieved by many able men in many special fields. Prof. Smith's fertile genius enabled him to marshal the leading facts of the theory, and to impress upon them his own personality in a manner that was scarcely within the reach of any other man. He contrived to impart a glamour to those abstract depths of the subject to which few mathematicians have sufficient faith and energy to penetrate. Since that day the scientific world has been yearly expecting his collected papers. There is no doubt that their appearance will greatly stimulate interest and research in Higher Arithmetic. The reports of the British Association are not sufficiently accessible. Doubtless the papers will soon emerge from the hands of those upon whom has devolved the responsibility of their production. In the meantime we welcome Part I. of the present work.

The theory of numbers is the oldest of the mathematical sciences, and may be regarded as their sire. Just as applied mathematics is based on pure, so pure mathematics rests on the theory of numbers. Every investigator finds that sooner or later his researches become a question of pure number. Continuous and discontinuous quantity are indissolubly allied. The theory of series, the theory of invariants, the theory of elliptic functions throw light upon and receive light from higher arithmetic. Algebra in its most general sense is everywhere pervaded by numbers. It may safely be affirmed that there is nothing more beautiful or fascinating in the wide range of mathematics than the interchange of theorem between arithmetic and algebra. A proposition in arithmetic is written out as a theorem in continuous quantity or conversely an algebraic identity is represented by a statement concerning discontinuous quantity. In this country the more recent advances in this attractive method are in large measure due to the labours of Sylvester and J. W. L. Glaisher. In a "Constructive Theory of Partitions," published some half-dozen years ago in the *American Journal of Mathematics*, Sylvester showed some beautiful progressions from arithmetic to algebra, and was followed in the same line by Franklin, Ely, and others, whilst in the pages of the *Quarterly Journal of Mathematics* and *Messenger of Mathematics* Glaisher has applied elliptic function formulas to arithmetical theory. The famous theorem which asserts that every number can be composed by four or fewer square numbers, was due to an application by H. J. S. Smith of elliptic functions to arithmetic. These interesting matters are not alluded to in this first volume.

Chapter I. discusses the divisibility of numbers and the elementary theory of congruencies. Euler's function $\phi(n)$, which denotes the number of positive integers, unity included, which are prime to and not greater than n, is not treated as fully as might be desired. Gauss's theorem

$$\phi(d) + \phi(d') + \phi(d'') + \ldots = n$$

where $d, d', d'', \ldots$ are all the divisions of n (unity and n included) is given, but not some interesting theorems connected with permutations, of which this is a particular case. Sylvester has written much about the same function, which he calls the "totient" of n. M. Ed. Lucas employs the term "indicateur" in the same sense, and believing that there is a great convenience in having a special name for the function, we regret that Mr. Mathews has not taken a course which would have familiarized students with Sylvester's nomenclature, and have enabled them to feel at home with much that has been written by him and others in this part of the theory of numbers.

The author states that this chapter is substantially a paraphrase of the first three sections of the "Disquisitiones Arithmeticæ," the classical work of Gauss; we are inclined to think that advantage would have been gained if the paraphrase had not been quite so close. The next succeeding chapters are occupied with "Quadratic Congruencies" and the theory of "Binary Quadratic Forms."

The account given is fairly complete. There are so many proofs of Legendre's celebrated "Law of Quadratic Reciprocity" that it must have been difficult to make a selection. A wise choice has, we think, been made of Gauss's third proof as modified by Dirichlet and Eisenstein; the latter's geometrical contribution to the proof taken from the twenty-seventh volume of Crelle is, in particular, of great elegance. Gauss's first proof is also given, as well as references to several others. In the difficult subject of Binary Quadratic Forms, the author keeps well in view the close analogy with the algebraic theory of forms; so many additional restrictions present themselves that a large number of definitions are requisite at the outset, and this circumstance is apt to repel a student who approaches the theory for the first time. The definitions, in fact, constitute the alphabet of the science which must be mastered before progress can be expected in the appreciation of the wonderful beauties which are inherent in it. In this subject, more almost than in any other, the initial drudgery must not be shirked, and it may be said in favour of the present work that clearness of definition and conciseness of statement help the learner much to get quickly over the wearisome preliminaries.

We are glad to see the prominence given to the geometrical methods of Klein and Poincaré; that of the former is based on the theory of substitutions, reminding the reader much of the "Icosaeder"; that of the latter is the "Method of Nets," a most ingenious geometrical application throwing light on the theory of "Reduced Forms."

The "Composition of Forms" given in Chapter VI. is logically and judiciously developed, by means of the bilinear substitution, up to the point of showing the method of tabulating the primitive classes of regular and irregular determinants. The chapter on cyclotomy is one of the best written in the book. The discussion of the section of the periods of the roots of unity has engaged the attentions of mathematicians of the first rank since the time of Gauss, so that of necessity much has been written, and while the author states that he has given but an outline of an extensive theory which has not yet been completed, it may be said that the theory as given, with the references to authorities at the end of the chapter, will be quite sufficient to conduct the student bent upon research to the frontiers of the unknown country.

The determination of the number of properly primitive classes for a given determinant, applications of the theory of quadratic forms, and the distribution of primes complete the volume. Mr. Mathews may be congratulated on his resolve to include Sylvester's masterly contraction of Tchébicheff's limits with reference to the distribution of primes; the reader is taken from the "sieve" of Eratosthenes to the work of Legendre, Meissel, Rogel, Riemann, and to the latest researches of Sylvester and Poincaré, of which the ink is scarcely dry. English mathematicians will turn with delight to the account given on page 302 of Riemann's great memoir of 1859, which contains the only satisfactory attempt to obtain an analytical formula for the number of primes not exceeding a given numerical quantity.

In conclusion, though the sequence of the subject matter may be open to criticism, we regard the book as a most valuable contribution to the small library of higher mathematical treatises that, owing chiefly to the energy and enthusiasm of the rising generation of mathematicians, is being brought together. How woefully deficient that library was but a few years since those engaged in research know only too well, and greatly do they rejoice as they see the yawning gaps one by one efficiently filled up. Part II. of the task Mr. Mathews has set himself to accomplish will, we hope, soon appear, and we trust he will be as successful with it as with the present Part I.

P. A. M.

THE DARWINIAN THEORY.

Darwin and After Darwin; an Examination of the Darwinian Theory and a Discussion of Post-Darwinian Questions. By George John Romanes, M.A., LL.D., F.R.S. I. *The Darwinian Theory.* (London: Longmans, 1892.)

WE had hoped ere now to have received the second instalment of this work, and to have dealt with the two volumes in a single critical notice. Unforeseen causes, one of them deeply to be regretted, have presumably prevented the appearance of the discussion of Post-Darwinian questions so early as had been anticipated. We therefore propose to give a short expository notice of the present volume, reserving such criticism as we have to offer for a future occasion, when the second volume shall have come to hand.

The first section consists of an exposition of the scientific evidences of evolution as a fact independent of the Darwinian theory of the method by which this evolution has been brought about. It may be regarded as an expansion of the author's little volume in the "Nature Series," on "The Scientific Evidences of Organic Evolution," published ten years ago. Mr. Romanes has spared no pains in the collection and marshalling of his evidence. His object is to convince, by the abundance of facts and by logical inferences based thereon, those who still hold by the tenets of Special Creation. Whether those who still hold by these tenets are likely to be influenced by the facts or the inferences is a question we do not propose to discuss. The author evidently supposes that they are, and has written for them a good many pages in a strain of which we give a couple of examples:—"It would seem most capricious on the part of the Deity to have made the eyes of an innumerable number of fish on exactly the same ideal type, and then to have made the eye of the octopus so exactly like these other eyes, in superficial appearance, as to deceive so accomplished a naturalist as Mr. Mivart, and yet to have taken scrupulous care that in no one ideal particular should the one type resemble the other." Again, "Although in nearly all the numerous species of snakes there are no vestiges of limbs, in the Python we find very tiny rudiments of hind-limbs. Now, is it a worthy conception of Deity that, while neglecting to maintain his unity of ideal in the case of nearly all the numerous species of snakes, he should have added a tiny rudiment in the case of the Python—and even in that case should have maintained his ideal very inefficiently, inasmuch as only two limbs, instead of four, are represented?"

The second section of the volume is devoted to the setting forth of the theory of natural selection as it was held by the master. This, as was to be expected, is a well-ordered and lucid exposition. We could wish that Mr. Romanes had been more careful to avoid all appearance of personifying natural selection. He says, for example, "it is the business of natural selection to secure the highest available degree of adaptation for the time being." Such language is highly metaphorical, if not misleading. If we can talk of business at all we may say that it is the business of various eliminating agencies, in the struggle for existence, to weed out and exclude from any share in perpetuating their race all those individuals who are too weakly to stand the stress of the struggle. The survival of the fit is an incidental result of the stern business of elimination. It is here that the naturalistic hypothesis differs most markedly from the teleological interpretation of nature. In conversation a while since a friend observed to us: Since your school of thought admit that the eye of natural selection is ever on the watch for the slightest improvement in adaptation, why should they hesitate to say with us that it is the eye of Beneficence that is thus ever watchful? The misunderstanding of the naturalistic position here shown is not surprising. It is due to the too free use of metaphorical language on the part of expounders of the Darwinian hypothesis.

In the chapter entitled "Criticisms of the Theory of Natural Selection," an interesting digest is given of the work of Prof. Ewart and others on the electric organ of the skate, concerning which Mr. Romanes says, "I freely confess that the difficulty presented by this case appears to me of a magnitude and importance altogether unequalled by that of any other single case—or any series of cases—which have hitherto been encountered by the theory of natural selection." And he adds, "So that, if there were many other cases of the like kind to be met with in nature, I should myself at once allow that the theory of natural selection would have to be discarded," by which he means, we presume, that the theory would have to be discarded as offering a solution of such cases.

The book contains many excellent illustrations, the series which show the variations due to artificial selection being a noteworthy feature. They, and the volume which contains them, will prove of service to those general readers for whom, as the author tells us in his preface, this exposition of the Darwinian theory has been mainly prepared.

FERNS OF SOUTH AFRICA.

The Ferns of South Africa, containing Descriptions and Figures of the Ferns and Fern-allies of South Africa. By Thomas R. Sim. 275 pp., 159 plates. (Cape Town and Johannesberg: J. C. Juta and Co. London: Wm. Wesley and Son, 1892.)

THE present work will be a useful and acceptable addition to our stock of fern-books. It contains descriptions and plates of all the ferns and fern-allies known to exist in Africa south of the tropic of Capricorn, the same area which is included by Harvey and Sonder in their "Flora Capensis," three volumes of which, including the orders from Ranunculaceæ to Campanulaceæ, have been published. The author won the Jubilee gold medal given by the North of Scotland Horticultural Association, and for many years has filled the post of curator of the Botanic Gardens at King William's Town. Several years ago Mr. Sim published an illustrated handbook of the ferns of Kaffraria, and now he has extended his area so as to include the whole of South Temperate Africa.

The fern flora of the Cape does not show the same richness and remarkable individuality which characterises its phanerogamic flora. It is probable that the flowering plants of this area are not less than ten thousand, and the number of large endemic genera and of species is very considerable. In ferns we get in South Africa 179 species, out of which 42 species, or something under 25 per cent., are endemic. There is no genus that is peculiar to the Cape; of Mohria, which comes nearest, the Cape species, *M. caffrorum* extends to Madagascar and Tropical Africa, and two new species have lately been found in the high regions north of the colony. The section Rhizoglossum of the genus Ophioglossum, which differs from the true adder's tongues by having the fertile spike separate from the barren frond, the single species, *O. bergianum*, is peculiar to the Cape. Hymenophyllum is represented by 8 species, Trichomanes by 5, Adiantum by 6, Cheilanthes by 8, Pellæa by 14, Pteris by 7, Lomaria by 5, Asplenium by 25, Nephrodium by 12, Polypodium by 12, Acrostichum by 8; and Lycopodium by 8 species. Some of the species, *e.g. Vittaria lineatia*, *Marattia* and the two tree-ferns, are tropical types; some, such as *Cystopteris fragilis* and *Lycopodium clavatum*, are common to Britain and the Cape. *Todea barbara* is confined to the Cape and Australia, and abundant in both areas. *Lomaria alpina* is a plant of all the three south-temperate areas. *Blechnum australe* of the Cape is not, I think, really distinct specifically from *B. hastatum*, and is widely spread in South Temperate America.

Lomaria punctulata is remarkable for its polymorphic fructification, which is sometimes like that of a Scolopendrium. *Asplenium lunulatum* is remarkable for its variability in outline and cutting.

Mr. Sim gives introductory chapters on the parts of ferns and their nomenclature, on their reproduction and propagation, on their cultivation and the preparation of herbarium specimens, and on the history of the discovery of the Cape species and the books and papers that have been written about them. His statistic table on page 34 needs much revision in some of its items. He gives the ferns of Madagascar at 144. The number now known in the island is 326 true ferns and 40 fern allies, a total of 366. There are nothing like 683 species and 458 endemic types in Africa and its islands. When I counted them up in 1868 I made the two figures 346 and 127. Since that date probably 100 species have been added. Madagascar, Bourbon, and Mauritius are very rich in ferns, but Continental Africa is very poor both in number of species and in peculiar types as compared with Asia and America.

The descriptions are carefully drawn up from the study of actual specimens, and by the aid of these and the plates there can be no difficulty for any one, even without any previous botanical knowledge, in making out the name of any reasonably complete specimen of any of the Cape species.

Therefore, no doubt, the existence of such a book will give a great impulse to the study of ferns by ladies and others who reside in or visit the Colony.

J. G. BAKER.

OUR BOOK SHELF.

Newcomb-Engelmann's Populäre Astronomie, Zweite vermehrte Auflage. Herausgegeben von Dr. H. C. Vogel. (Leipzig: Wilhelm Engelmann, 1892.)

THE well-known Popular Astronomy of Prof. Newcomb was translated into German by Rudolf Engelmann, and published in 1881 with considerable additions and alterations, most of which were improvements. It was very favourably received on its first appearance in German, probably because it is not only comprehensive, exact, and scientific, but has a fresh and vigorous style, in pleasing contrast to the ponderous German standard works. The original translator being dead, the publishers entrusted the work of preparing a new edition to Dr. H. C. Vogel, Director of the Astrophysical Observatory at Potsdam, a task for which he was specially fitted, because astronomical progress during the decade since the appearance of the first edition of the book has been mainly in his special department. Dr. Vogel's chief difficulty has been to keep the book within reasonable limits while bringing it up to date, but he has not been wholly successful in this. By a slight further enlargement of the book he might without difficulty have very much increased its value. A description of the diffraction spectroscope should have been given in the section on spectroscopes; Prof. Hale's work in photographing prominences and faculæ should have been introduced; the chapter on Mars is very much behind the times; and some details should certainly have been given of the international scheme for photographically charting the stars.

Dr. Vogel has considerably altered the arrangement of the chapter on comets and meteors, and this alteration has led to the curious result that the same woodcut appears as Figs. 152 and 165. The chapter on stellar astronomy is also recast, the editor's own latest classification of star spectra being given to the exclusion of all others. The section on variable stars has also been entirely rewritten. These chapters would have been much improved by an account of recent discoveries as to the resemblances between comets, nebulæ, and stars, and of the theory that variable stars are formed of revolving swarms of meteorites. The classification of star spectra which recognises an ascending and descending temperature should have been given, and recent work and theories on temporary stars certainly deserved attention. The bibliography given in the first edition has been omitted in the second, as being too much for the general reader, and insufficient for the student of science. The excellent series of biographical notices in the appendix has been carefully extended to 1891, and completely rearranged. Dr. Vogel has adopted the admirable plan of arranging these notices chronologically in order of death, instead of birth, probably on the grounds that all work is largely the result of previous discoveries, and that the later years of a man's life are usually his best and most productive. A series of excellent tables and a full index complete the volume.

The general appearance of the book has been much improved by the use of new woodcuts for the illustrations, and by the substitution of two excellent photographs of nebulæ (those of Orion and Andromeda) for the very unsatisfactory star charts of the earlier edition.

A. T.

The Hemiptera Heteroptera of the British Islands. By Edward Saunders, F.L.S. (London: L. Reeve and Co., 1892.)

It is now nearly thirty years since Douglas and Scott first made the study of the British Hemiptera Heteroptera possible to ordinary students by the publication of a description of these insects in a volume issued by the Ray Society. The difficulties were then very great, for purely insular ideas in entomology were prevalent, and our hemipterous insects had not been sufficiently compared with continental species. Douglas and Scott did all that was possible at that time and produced a good work that has held the ground as the best published authority on the subject. Very much, however, has been done since that period, and restricted specialists in entomology, as in most other branches of natural science, have exercised unlimited time and patience in studying the classificatory problems of a single family or even of a large genus. Hence in a monograph of to-day the standard of advanced classification and descriptive facility is considerably raised from that which dominated the writings of the earlier authors. Mr. Saunders has not only aimed at this perfection, but has sought to place in the hands of the British student and collector a thoroughly trustworthy handbook by which he may understand and identify his collection, and in this we think the author has altogether succeeded. We must not look for bibliographical references or synonymical notes, the names of the describers of families, genera, and species being only indicated, while the habitats of the species are confined to such localities in the British Islands as are recorded by collectors; and this is perhaps all that can be expected in a local monograph. It is therefore in no spirit of criticism we express a regret that in all faunistic writings the complete recorded distribution of the species is not given. Thus even the purely British collector would not be the worse for learning that *Zicrona cœrulea*, to be found in the suburbs of London, is not only widely distributed throughout the Palæarctic region, but is also found in Continental India and in the Malay Peninsula and Archipelago; or that *Ischnorhynchus resedæ*, to be taken even at Hampstead, is common throughout Europe and Siberia, and is also neither scarce in North nor in Central America.

We welcome Mr. Saunders's book as a distinct and valuable addition to our insular entomological literature. We also notice that an illustrated edition is advertised, but on the quality of the plates we are compelled to be silent, as the publishers have only forwarded us a plain copy.

W. L. D.

Physical Education. By Frederick Treves, F.R.C.S. (London: J. and A. Churchill, 1892.)

THIS essay is reprinted from the "Treatise on Hygiene" by various authors, edited by Stevenson and Murphy, the first volume of which we recently reviewed (NATURE, vol. xlvi. p. 609). It well deserves to be issued separately, for the author has mastered his subject thoroughly, and sets forth his ideas in a plain, straightforward style which will be cordially appreciated by readers who are especially interested in athletics. Mr. Treves is quite as strongly conscious of the evils which may spring from excessive or unsuitable physical exercise as of those which may result from physical exercise being neglected or underrated, so that there is a welcome tone of perfect impartiality in all he has to say about the various ways in which efforts are made to promote health by the use of the muscles. The volume may be confidently recommended to all who desire to understand the conditions under which physical exercise is most likely to be of service.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Geology of the North-west Highlands.

IN the kindly review of my work by Prof. de Lapparent, which appeared in NATURE of 5th inst., there are one or two inaccuracies which I would at once have corrected had I not shrunk from drawing attention, even for purposes of rectification, to an article which I felt to be too eulogistic. Lest, however, my silence be misinterpreted, there is one point on which I wish to say a few words. Prof. de Lapparent, when alluding to the solution of the problem of the geological structure of the North-west Highlands, makes no reference to the distinguished part taken in that subject by Prof. Lapworth. But every one who has followed the progress of geology in recent years is familiar with his work. For myself, I have had no personal share in the discovery. Like most geologists I had accepted the views of Sir Roderick Murchison, and I held to them, until, after the Geological Survey was for the first time extended to Sutherland in 1883–84, I was finally convinced that they were untenable by the brilliant mapping of my colleagues, Messrs. Peach and Horne, who, following Prof. Lapworth's lead, share with him in the glory of one of the greatest achievements of field geology in recent times. My recantation was published in NATURE of November 13, 1884, and the whole history of the investigation of the North-west Highlands up to Prof. Lapworth's latest paper was sketched in a detailed Report communicated by me to the Geological Society on April 25, 1888. My friend Prof. Lapworth has no scientific comrade who has more frankly and practically acknowledged his great geological achievements than I have done.

ARCH. GEIKIE.

January 23, 1893.

The Identity of Energy.

I AM glad to see that in the introduction to his severely-difficult memoir, published in the *Philosophical Transactions* for 1892, "On the Forces, Stresses, and Fluxes of Energy in the Electromagnetic Field" (p. 427), Mr. Oliver Heaviside notices and criticizes some ideas of mine, published in the *Philosophical Magazine* for June 1885 and other places, concerning energy.

The statements I then made, and to which I still rigidly hold, are (1) that energy has identity like matter, and not merely conservation; (2) that whenever energy is transferred from one body to another, it is also transformed from potential to kinetic, or *vice versâ*.

The basis of the first assertion is the fact that energy is always passed on continuously through space, *i.e.* that its transfer occurs along a definite path, instead of merely appearing in one place and disappearing in another.

The law of conservation would be satisfied by disappearance and equal reappearance; the law of identity requires a continuous act of transfer. The latter is true for matter, and I assert that by thinking of a number of instances, it will be perceived true for energy. In all mechanical instances, as of belts and shafting, the transfer of energy is obvious; it was not so obvious in electromagnetic actions, between dynamo and motor for instance, until Prof. Poynting clearly demonstrated that it was in accordance with Maxwell's principles.

Mr. Heaviside objects that we are not able to assert it for gravitational energy. Well, that depends on what view we take of gravitation; but I submit that until something more is certainly known about it, the safest plan is not to assert, but to assume, that in this case also what is known in every other case likewise occurs, and to trace the consequences of the hypothesis in the hope that it may lead to some conclusion verifiable or falsifiable by experiment. The reason I attach importance to this doctrine of the identity or continuity of transfer of energy is because it greatly simplifies the fundamental mechanical laws, and emphasizes without risk of vagueness the denial of action at a distance.

If action at a distance (no matter how minute) can ever occur, then indeed the continuous transfer of energy breaks down. But observe that there is no necessity for the transfer to occur at a finite velocity in order to avoid action at a distance, *i.e.* action without a medium. By the thrust of an incompressible pole, energy is transferred from butt to tip, just as really as if the compressed and recoiling layers could be demonstrated and its velocity measured. So likewise the pull of gravitation may be (and *pro tem.* I believe is) transmitted by an incompressible (or nearly incompressible) ether, so that the force is felt instantaneously (or nearly instantaneously) at all distances where matter exists; but that by no means militates against a genuine act of transfer. The conservation of matter makes experiments on gravitation difficult; if we could suddenly create or destroy a piece of matter there might be some remote chance of determining the rate at which its gravitative influence was felt. Especially if by alternately generating and destroying it we could set up a series of waves of perhaps measurable length.

And although this is as yet impossible, many known facts lead us to conclude that if gravitation has any velocity at all short of infinite, it is at least immensely greater than the speed of light. And seeing that the one phenomenon is concerned with the transverse (electric) elasticity of ether, and the other with its longitudinal elasticity, there is nothing surprising in that.

By all means, however, as Mr. Heaviside urges, let gravitation be included in general etherial equations whenever possible; and it may perhaps be wise to assume some unknown finite rate of propagation and trace its consequences with the object of verifying or disproving them.

So far as I understand, however, this is not unlike what Helmholtz did, by his generalization of Maxwell's electromagnetic theory; with the result that the course of experiment so far has been to justify the simple Maxwellian theory, and to make the longitudinal ether thrust velocity practically infinite.

And now for the second assertion, that whenever energy is transferred from one body to another, it is also transformed, and *vice versâ*. This is to me not an opinion, but a demonstrated theorem (as has been shown in the paper referred to); but it must be understood in what sense I consistently use the word body in this connection. I do not necessarily mean a visible lump of matter. The molecules of a lump are to be regarded as a different "body" to the whole mass; and again, the ether everywhere embathing them is another distinct "body."

But so long as a piece of matter is merely moving through space with all the energy it may happen to contain, I do not consider that a transfer at all. There is a transfer of energy in one sense, viz. that of locomotion, but there is no transfer from one body to another except when work is done at their point of contact, and energy gained by one and lost by the other, being transferred across their common boundary surface. In all such cases of "activity" the energy transferred is necessarily in the first instance transformed; though by means of another transfer it may very speedily be transformed back again; and so speedily sometimes is the re-transformation effected that the intermediate condition has a tendency to get overlooked. In wave-motion a transfer and transformation occurs during every quarter period.

Mr. Heaviside seems to think that the mere convection of energy should be included as one kind of transfer; but surely that is scarcely convenient? So long as energy retains its form and adherence to one body, so long there is no true activity; no work is being done—the energy is simply stored. It may be stored in a bent spring, or in a flying bullet, or in a revolving fly-wheel. It is impossible to have kinetic energy at all without convection, and a distinction must be drawn between the mere existence of energy and the active and useful flux or transfer of the same.

Mr. Heaviside further seems to consider circuital fluxes of energy as strange and useless phenomena. But I see no reason in this at all. The circulation of matter—for instance in the inner circle of the Metropolitan railway—is, I suppose, considered useful. The circulation of commodities is the essence of commerce. So does the circulation of energy constitute the activity of the material universe. It is the act of transfer that is beneficial (or the reverse); what becomes of a conservative quantity is a minor matter. It must go somewhere, and may very well, after a series of transfers, ultimately return to its starting point. [Parenthetically I should like to preach here against what I hold to be the pernicious doctrine of (at least amateur) political economists, that because money locally spent is not destroyed, but remains in the community, it does not much matter how much transferring power is permitted or granted to one individual,—as if the money itself were the useful commodity, and not the power of determining its direction of transfer or non-transfer. The control of every transfer should be jealously watched, for that is the greedily-desired power.]

So long as circuital convection of energy goes on *without* transfer—as, for instance, in the rim of a non-working fly-wheel—so long the energy is merely *stored*; but directly a belt is fitted on with different tensions in its two halves, a portion of the energy is tangentially tapped off, and transfer and activity begin. The kinetic energy of the wheel is converted into strain or stress energy of the belt, which then by simple locomotion passes it on to something else. I perceive, however, that there is a slight difficulty about this simple case of locomotive conveyance of stress energy by a really inelastic substance; but only because the details of any infinitely rapid process are difficult to follow. I perceive moreover that in many cases it is not worth while to attend to the alternate compressions and motions which constitute a longitudinal pulse, and that the idea of simple locomotion may be conveniently introduced to cover the case of a stressed body moving; but the convenience is I think only attained by shutting our eyes to the essential processes which in all actual matter must be occurring.

I trust that Mr. Heaviside may find time to notice this letter, and attack anything he disagrees with, in order that the whole matter may become thoroughly clear.

OLIVER LODGE.

A Proposed Handbook of the British Marine Fauna.

I AM obliged to Prof. Thompson for his criticism of my scheme, although only one of the points he raises is new to me—as I think it will be to most zoologists—viz. that "there are *no* nematophores on the stem" in *Antennularia*. I thought *A.*

ramosa had nematophores on the stem, *and I think so still.* Some of his other remarks are so very obvious as to have scarcely required mention, at any rate to biological readers; a few, however, are just such debateable points as I was anxious to have opinions upon from as many naturalists as possible, and I am glad to know Prof. Thompson's. I am glad to say a number of biologists have written to me, since the scheme appeared in NATURE, expressing general approval, and criticising various points of detail, and some of them kindly making offers of assistance in special groups—and without that kind of assistance from specialists I need scarcely say it would be impossible to carry out the work satisfactorily. The proposal was first brought before the Biological Society of Liverpool on November 11, and it was only after some weeks of intermittent discussion with some of my friends in that Society (such as Dr. Hanitsch, Mr. Isaac Thompson, and Mr. A. O. Walker) who are specialists in certain groups of marine invertebrata, and after correspondence with Canon Norman and other biologists, that I sent the scheme to NATURE, with the view of getting further opinions. Consequently some of the debateable matters alluded to by Prof. Thompson (limits of British area, introduction of certain non-British forms, specific nomenclature, how to treat records of size and distribution, best terms to use for zones of depth, and, I may add, for relative abundance) have already been considerably discussed. The other points raised by Prof. Thompson in connection with *Antennularia* only require a few words. I said *A. ramosa* was *usually* branched. Prof. Thompson says it "may sometimes" be unbranched. The difference between these statements is slight. As to dimensions, a zoophyte which grows to 12, or occasionally to 24, inches in height, will, of course, be also frequently found of smaller sizes; and it might be the best plan to give the extreme range, say, 1 to 24 inches. What I gave was the fair average size of most of the specimens dredged or seen in collections, which I still consider to be 6 to 9 inches.

The rest of Prof. Thompson's contention is practically that there are great difficulties in the way of drawing up such a book of the known British marine invertebrate animals, and that if it is ever done it will be more or less incomplete, because Canon Norman and others (I hope including both Prof. Thompson and myself) will continue to find new British animals. That is perfectly true—in fact obvious—but the same objection applies more or less to every work on systematic zoology that has ever been published; and I do not consider that because our British Pycnogonids, and some other small groups, are still very imperfectly known, that is any sufficient reason for delaying indefinitely an attempt to deal with the rest of the invertebrata. On the contrary my opinion is rather that an approximation is better than nothing, and that every group, or every family, reduced to "Handbook" form with specific diagnoses and figures must be a distinct gain. I hope Prof. Thompson will not think that I am trying to dispute all his criticisms, or that I am ungrateful for the trouble he has taken. I have no doubt that he could correct me in many details, and give me great assistance in records, &c., of zoophytes, pycnogonids, and other groups, and I hope he will do so.

W. A. HERDMAN.

University College, Liverpool, January 20.

PROF. D'ARCY THOMPSON'S letter raises a question which is, I think, well worthy of Prof. Herdman's consideration. That a handbook of our marine fauna is needed cannot for a moment be doubted, and the only matter that calls for discussion is one of scope and method, of ways and means. Prior to the appearance of Prof. Herdman's circular and article I had intended, if possible, to bring this very matter before the British Association at its next meeting, believing that a select Committee of the Association would best be able to further the interests of marine zoology in this respect. But, as the matter now stands, I leave any such action very willingly to Prof. Herdman's initiative.

Put broadly (although I well know that such a work in Prof. Herdman's hands would by no means have the character of a mere compilation), the question at issue is whether the handbook should be mainly a compilation from existing material, or should express the work of various specialists and be based upon a series of special investigations. For myself I agree with Prof. Thompson, and for the same reasons, that the adoption of the latter alternative would be likely to meet our needs most fully and satisfactorily. It would ensure, as far as possible, the equal treatment of the various groups, and would thus give to the book (which is important) a more permanent and authoritative value than could be attained by a book depending upon the personal labours of one zoologist. I feel confident that, should Prof. Herdman admit the force of this consideration and be willing to edit a handbook in which the diagnoses were drawn up for the various groups by specialists or specially-chosen investigators, he would find no difficulty whatever in meeting with willing co-operation.

But I hardly see the point of extending the scope of the work to the extent which Prof. Thompson would seem to desire. We need a handbook for use around the coasts of our own islands. To include the fauna of the whole North Atlantic would needlessly add to the size of the work, delay the time of its appearance, and even in the end be incomplete; while it is doubtful whether the advantages would at all outweigh these defects.

W. GARSTANG

Marine Biological Association, Plymouth, January 20.

Fossil Plants as Tests of Climate.

MR. J. STARKIE GARDNER, in his interesting review of Mr. Seward's valuable essay, makes a statement which I fancy may be misinterpreted at page 268 of NATURE, where he speaks of the fragmentary character of the Arctic tertiary plants, and the inexperience of the collectors. He doubtless is referring to the remains of certain supposed "palms and cycads in the Greenland Eocene," but those who have not followed this branch of Arctic research would hardly gather from the review that Prof. Heer has determined a magnificent flora of more than 350 species from these northern tertiaries, and that he at once pointed out the absence of tropical and subtropical forms, and the fact that large leaves are not only perfectly preserved up to their edges, but that upright trees associated with their fruits and seeds prove them to have grown on the spot. "Thus of *Sequoia Langsdorffi*," he writes, "we see not only the twigs covered with leaves, but also cones and seeds, and even a male catkin."[1]

In April 1875 I endeavoured to give an abstract of all that was then known of Arctic geology, in a series of articles that appeared in your columns (NATURE, vol. xi. pp. 447, 467, 492, and 508), and added some general conclusions of my own, which are further accentuated in the joint communications of Colonel Feilden and myself to the Geological Society in 1878, and in the "Geology Appendix" to Sir George Nares' "Voyage to the Polar Sea," in which expedition Colonel Feilden played a most valuable part. I have ever since carefully followed the progress of Arctic research, and am now of opinion that looking to the identity of a large number of species (often extending to the varieties of the same) occurring in the Silurian, Carboniferous, Lias, Oolite, Cretaceous, and Tertiary strata of the Arctic regions, with those occurring in similar strata in Europe and other parts of the world, they point to a common temperature over these areas and probably over the whole world, from Silurian to early Cretaceous times, and that this was the case does not appear to me to be affected by the question as to whether or not these deposits were homotaxeous.

In late Cretaceous times commenced *horizontal* variation of cold, or what we now term "climate," though previously *vertical* variation had evidently been present, for the later investigations of Messrs. Blanford appear to place beyond doubt the existence of glaciers in geological times, as was suggested in 1855 by my lamented chief, Sir Andrew Ramsay; but I equally fail to see that the slightest evidence has been anywhere adduced to support the theory of "recurrence of ice-ages," originated by my talented colleague the late Dr. Croll, and now supported with a "modification" by Sir Robert Ball.

The facts, whether we look to the history of plant life, or animal life, or the character of the rocks themselves, appear to me to be all the other way, as they disclose nothing resembling the refrigeration that, gradually increasing in the Tertiary epoch, culminated in the Glacial episode, which choked up the North and Irish Seas with an ice-sheet since man has been an occupant of our islands.

CHAS. E. DE RANCE.

H.M. Geological Survey, Alderley Edge, Manchester.

Racial Dwarfs in the Pyrenees.

IN consequence of evidence that I had obtained as to the existence of a dwarf race in Spain, I wrote to Mr. McPherson, our Consul at Barcelona, and enclose his reply. There have long been rumours of survivals of a dwarf or a prehistoric race existing in parts of Spain, but careful inquiries at Madrid failed to supply any definite information on the subject. Last summer on reading over an old number of *Kosmos* (Paris, 1887), I found a brief paragraph referring to a pigmy race having been found in the province of Gerona, Spain, who had slightly Mongolian eyes, yellow, broad, square faces, height from 1 m. 10 to 1 m. 15, and red hair.

---

[1] "On the Miocene Flora of North Greenland," by Prof. Oswald Heer. Translated by R. H. Scott, F.R.S., Brit. Assoc., 1867, pp. 53.

An Austrian gentleman recently told me he had seen, in the market-place at Salamanca, some very under-sized peasants, with broad faces and mahogany-coloured woolly hair.

You will see that these accounts all agree substantially, and that these dwarfs and those of Africa are precisely similar.

I have got a deal of information from an old Spanish woman who belongs to a half-breed nano family, and who says that there are in such families frequently nanos (or "enanos") who have red tufts of wool, and are as small as ordinary small boys. But these tufts of wool are peculiarly characteristic of dwarf races nearly everywhere.

I shall write more fully as to my inquiries among half-breed nanos; but they are of very secondary interest now that we can find pure racial nanos within easy reach.

It is most fortunate that they live in the Valley of Ribas and the Col de Tosas, within a little more than a half-day's journey from Toulouse. Some health-seekers or tourists in the South of France may perhaps feel inclined to pay a visit to these little people.

Should the suggestion be acted on, and prove satisfactory, a line to myself on the subject, addressed to 28, Pall Mall, would be highly valued. R. G. HALIBURTON.

Tangier, January 9.

[COPY.]

"*British Consulate, Barcelona, December* 10, 1892.

"DEAR SIR,—Since I received your letter of November 18 and its enclosures I have endeavoured to ascertain what truth there is in the statement that pigmies, or 'enanos' (not 'nanos') exist in the Valley of Ribas. From conversations I had with various individuals who have visited that district it appears certain that a race of men, of about from one metre to one metre and twenty centimetres high, of a darkish complexion (copper-coloured), dark hair and woolly, and flat, broad nose, live in that district, particularly in the 'Collado de Tosas.' They are active, and are generally employed as shepherds. It is also asserted that they are not very intelligent, and that they appear to understand and to make themselves understood with difficulty. It would be an easy journey to go to that place from this town. I had no little difficulty in finding out that such a race lived in that place, for many of the persons with whom I have spoken on the subject were evidently confused and confused me, as besides these, evidently racial pigmies, there are in that neighbourhood many 'cretins,' which were at times described to me as if these were the 'enanos' I spoke about. I am now certain that there are cretins and pigmies in the Valley of Ribas. It is stated that the 'enanos' are rapidly disappearing, and that latterly many have died of smallpox. The men you speak of, who were seen at Salamanca, are, I should say, natives of the Batuecas, or rather of Los Hurdes. These men were discovered in the sixteenth century, and they were then and are even now, in an almost absolute state of savagery." [The remainder as to this race is omitted, as it does not appear that they are nanos.—R. G. H.]

"Yours very truly,
(Signed) "WM. MCPHERSON.
"R. G. Haliburton, Esq."

British Earthworms.

I WRITE to suggest—in connection with the recent letters in NATURE upon this subject—that some one give a thoroughly trustworthy list of British earthworms, with the memoirs in which the species were originally described, and the chief characteristics of each. Dr. Benham would be doing very useful and acceptable work if he were to accomplish this. From what I understand everybody has been making mistakes, and the whole matter is in the utmost confusion. It is very necessary that such a classification should exist, if only for the benefit of those who are working on the earthworm more from a comparative anatomist's than from a specialist's point of view.

FRANK J. COLE.

Zoological Department, Edinburgh, January 12.

DANTE'S "QUÆSTIO DE AQUA ET TERRA."

"Quæstio Aurea ac perutilis edita per *Dantem Alagherium*, poetam florentinum clarissimum, de natura duorum elementorum Aquæ et Terræ disserentem."

"Lo, the past is hurled
In twain: up thrust, out staggering on the world,
Subsiding into shape, a darkness rears
Its outline, kindles at the core, appears
Verona."—R. BROWNING, "Sordello," Book i.

"TO all and each who shall see this document, *Dante Alighieri* of Florence, the least amongst true philosophers, wishes health in Him who is the Beginning of truth and the Light.

"Be it known unto ye all that whilst I was at Mantua there arose a certain question, the which after having been many times dilated upon rather for vain show than for Truth's sake, still remained undecided. Wherefore I, since from boyhood I have been nurtured continually in love of Truth, could not bear to leave the question undiscussed; but I thought fit to show the truth concerning it and to dissolve the arguments adduced to the contrary, both for love of Truth and hatred of Falsehood. And lest the malice of many who are wont to fabricate envious lies against the absent should behind my back alter what was well said, I have moreover thought fit to leave written down on paper what I proved, and to set forth the form of the whole disputation."

These are the words with which Dante commences this "golden and most useful" inquiry concerning the nature of the two elements, earth and water. The treatise is little known in comparison with the other writings of the poet;[1] but although rejected by Ugo Foscolo and others as "impostura indegna d'esame," its genuineness and importance are now almost universally admitted; and without yielding unreservedly to the enthusiastic opinion of an Italian geologist (Stoppani) that there are more truths relating to cosmology to be found prognosticated, affirmed, and even demonstrated in these few pages of the supreme poet than in all the writings of the middle ages taken together, we may nevertheless acknowledge it to be a work of the greatest interest and importance, and by no means unworthy of the singer of the "Divina Commedia."

It seems to be the last work of the poet's life, written at that period which he himself describes in his sonnet to Giovanni Quirino:—

"Lo Re, che merta i suoi servi a ristoro
Con abbondanza, e vince ogni misura,
Mi fa lasciare la fiera rancura,
E drizzar gli occhi al sommo consistoro
E qui pensando al glorioso coro
De' cittadin della cittade pura,
Laudando il Creatore, io creatura
Di più laudarlo sempre m'innamoro."
—Sonetto xliv. ed. Fraticelli.[2]

Dante was at this time the guest of Guido Novello di Polenta at Ravenna. About the commencement of the year 1320, he seems to have gone for some unknown reason to Mantua, and there to have entered upon this discussion, which he then completed at Verona. The disputation took place at this latter city on January 20, 1320, as Dante himself tells us, in the church of St. Helena (where in recent years the metropolitan chapter have put up a monument in commemoration of the event). All the clergy of Verona were present, except some few who, in the words of Rossetti—

---

[1] It is, I believe, the only one of Dante's writings that has not yet been translated into English.

[2] "The King by whose rich grace His servants be
With plenty beyond measure set to dwell,
Ordains that I my bitter wrath dispel
And lift mine eyes to the great consistory;
Till, noting how in glorious quires agree
The citizens of that fair citadel,
To the Creator I, His creature, swell
Their song, and all their love possesses me."
—Rossetti's translation in "Dante and his Circle."

> "Grudged ghostly greeting to the man
> By whom, though not of ghostly guild,
> With Heaven and Hell men's hearts were fill'd."
> —"Dante at Verona."

From a passage which occurs in the course of the treatise, one might almost think that ladies also were present, but let not the reader therefore conclude that the assemblage which listened to Dante's eloquence in that little Veronese temple resembled so many modern philanthropical and other associations in being chiefly composed of ladies and clergymen, for doubtless Can Grande della Scala himself was present to do honour to his former guest, and his poetic fame, which we know to have already spread far and wide, would certainly have brought together as many as the church could hold.

The question to be solved is whether, on any place on the earth's surface, *water* is higher than the *earth*. This question, Dante tells us, was generally answered in the affirmative, and he gives us the five chief reasonings adduced in support of it, of which perhaps the most striking is this one:—

"If the earth were not lower than the water, the earth would be entirely without waters, at least in the uncovered part, and so there would be no fountains, nor rivers, nor lakes. So water must be higher than the earth. For water naturally flows downwards, and the sea is the source of all waters, and if the sea were not higher than the earth, the water would not flow to the earth, since in every natural motion the source of the water must be higher."

Another is this:—"Water seems chiefly to follow the motion of the moon, as is evident in the flow and ebb of the sea, and therefore since the moon's orbit is eccentric, it seems reasonable that water in its sphere should be eccentric too; and another argument shows that this cannot be unless it be also higher than the earth."

Such be their arguments, but sense and reason alike are against them, and Dante proceeds to explain how he will treat the question. First, he will prove that it is impossible that water in any part of its circumference be higher than this emergent or uncovered earth on which we dwell. Secondly, he will prove that this emergent earth is everywhere higher than the surface of the sea. Thirdly, he will urge arguments against his own demonstrations, and then demolish these objections. Fourthly, the final and efficient cause of the elevation and emergence of the earth will be shown. Fifthly, he will demolish the five chief arguments of the other side which he has already stated.

1. It is impossible that water in any part of its circumference be higher than the earth.

There are only two ways whereby water can thus be higher than the earth: either the water must be *eccentric*, or, if it be *concentric* with the earth, it must be *gibbous* in some part. By water being *eccentric*, Dante means the centre of its natural sphere to be out of and different from the centre of the earth; by being *gibbous*, Dante means some part of its sphere to be raised up so as to form a protuberance or hump, just as he considers the earth on which we live to be a protuberance or gibbosity of the spherical surface of the earth.

He now shows by means of diagrams that neither of these things are possible, but first makes these two statements—(1) Water naturally flows downwards; (2) Water is by nature a labile body and has not a boundary of its own, but takes the boundary of the thing in which it is contained.[1]

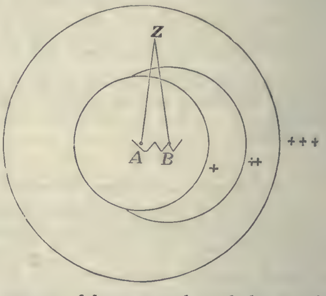
We may compare with this a modern definition of a fluid:—

"A perfect fluid is a body whose form can be changed to any extent, provided its volume remain constant, by the application of a stress, however small, if we allow it sufficient time."—Garnett, "Treatise on Heat."

In the first place, *water cannot be eccentric.*

For if it were so, then three impossibilities would follow—(1) Water would naturally flow both upwards and downwards; (2) water would not be moved downwards by the same line as the earth; (3) an equivocation would arise in speaking of the *gravity* of water and of earth; all which things are seen to be not only false but impossible.

The demonstration *ab absurdo* follows thus:—Let the heavens be the circumference on which are placed three crosses; water the circumference on which are two; earth the circumference on which is one cross.



Let the centre of heaven and earth be at point A, the centre of water at point B. Thus A, being the centre of the universe, is the lowest spot of all, and everything which has in the world a position alien from A must be higher. Now if there be any water at A and the way be open to it, it will naturally flow to its own centre, B, since it is the property of every heavy body to move to the centre of its own sphere. But the motion from A to B is a motion upwards; therefore water will flow *upwards*, which is impossible.

Again, let there be at Z a lump of earth and some water, and let there be nothing to hinder. Then, since it is the property of every heavy body to move to the centre of its own sphere or circumference, the *earth* will move in a straight line to A, and the *water* in a straight line to B, and this, from the figure, must needs be along different lines. This, says Dante, is not only impossible, but would make Aristotle laugh if he were to hear it.

The third impossibility follows thus:—*Gravity* and *levity* are "passions" of simple bodies which are moved with linear motion, and *light* bodies tend upwards and *heavy* tend downwards, by "heavy" and "light" being meant that which has the power of being moved. If now water moved to B and earth to A, since these are simple bodies and heavy, they will be moved down to different centres. If this were so, the word *gravity* would have an *absolute* signification with respect to earth and *relative* with respect to water. This is what the argument amounts to, and so there would be an equivocation of meaning in the word "gravity."

Therefore, *ab absurdo*, water in its natural circumference is not eccentric or out of the centre common to the circumference of the earth.

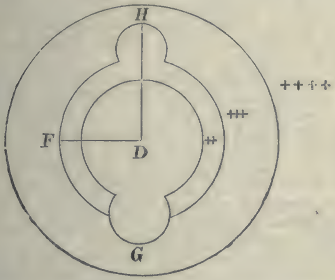
In the second place, *water cannot be gibbous.*

---

[1] "Aqua est labile corpus naturaliter, et non terminabile termino proprio."—§ xi.

Let the heavens be where are four crosses, the water where three, the earth where there are two.

Let D be the centre of *earth* and concentric *water* and *heaven*. Water cannot be concentric with the earth unless the earth be in some part "gibbous" above the central circumference. Let the protuberance of the earth be at G, and at some part of the circumference of water let there be a protuberance of water at H. Then let a line be drawn from D to H and another from D to F; it is manifest that D H is longer than D F, and therefore the summit of one is higher than the summit of the other. Since both touch at their summit the surface of the water without passing beyond, it is clear that the water of the protuberance will be higher, with regard to the surface where F is. Since, therefore, there is no obstacle, the water of the protuberance will flow down until it become level at D with the central or regular circumference. And thus it will be impossible for a protuberance of water to last or even to exist.—Q.E.D.



Dante now brings forward a subsidiary argument to show that probably water has no protuberance out of the regular circumference. The protuberance of the earth is sufficient to prove and explain everything, and "Quod potest fieri per unum, melius est fieri per unum quam per plura." So there is no protuberance on the surface of the water, because God and Nature always do what is best and do not work in vain.

Since water cannot be eccentric, as was shown by the first figure, nor concentric with a protuberance, as was shown by the second figure, it is necessary that water be concentric and coequal, *i.e.* equally distant in every part of its circumference from the centre of the world.

Thus it has been proved impossible for water in any part of its circumference to be higher than the surface of the earth; and so the first point is completed.

We now pass on to the second.

2. This emergent earth is everywhere higher than the surface of the sea. This is shown in this way:—

All the shores of the ocean, as well as of the Mediterranean seas, rise above the surface of the sea which bounds them, as is clear to the eye. Therefore all the shores are further from the centre of the world, since the centre of the world is also the centre of the sea and the shoreward surfaces are parts of the whole surface of the sea; and since everything that is more remote from the centre of the world is also more high, it follows that the shores everywhere rise above the surface of the sea. And if the shores are higher than the sea, much more must be the other regions of the earth, since the shores are the lower parts of the earth, as we see by the rivers flowing down to them.

3. In accordance with the order of the question as at first stated by Dante, he now brings forward various arguments which seem to contradict his demonstrations, and these arguments he then proceeds to demolish. They need not detain us here. In the course of the operation there occurs a most interesting distinction between *homogeneous* and *simple* bodies, in which I seem to see a distinct foreshadowing of our modern view of the chemical elements in contradistinction to the ordinary four or five elements of Aristotle and his followers. "Corpora enim homogenea et simplicia sunt; *homogenea ut aurum depuratum;* et corpora simplicia, ut ignis et terra." § xviii.

But perhaps it might not be out of place to quote here the following passage from G. H. Lewes's "Aristotle":—"One of the great difficulties in interpreting ancient opinions is to guard against the tendency of reading our fulness of knowledge into their vague expressions. We often find in ancient works the precious metal we have ourselves brought with us; as the alchemist often unconsciously put into his crucible the gold, which he afterwards discovered there with surprised delight."—G. H. Lewes, "Aristotle," x. § 170.

He thus sets forth the *final* cause of the elevation or emergence of the earth: There must needs be a part in the universe where all *miscibilia*—to wit, elements—can come together; this cannot be unless the earth be in some part emergent. Thus, although earth, according to its own nature, tends always downwards, it has in it another nature by which it obeys the intention of Universal Nature, and allows itself to be here and there raised up, in order that mixture of the elements may be possible, and thence all things that are subject to generation and corruption may be formed.

He further shows that the emergent earth on which we dwell has the form of a semilune, by arguments which he graciously tells us that even ladies can follow—"Manifestum esse potest etiam mulieribus."

4. What now is the *efficient* cause of the elevation or emergence of the earth above the surface of the water?

Dante first shows that neither the *earth* itself, nor *water*, nor *air*, nor *fire* can be the efficient cause. Therefore it must be referred to the *heavens*. But there are many heavens, and to which are we to refer it? Dante shows that it cannot be referred to the *moon*, nor to the heavens of any of the planets (Mercury, Venus, the Sun, Mars, Jupiter, Saturn), nor yet to the Crystalline Heaven or *Primum Mobile*, the 9th sphere. Now, since the only mobile bodies which remain are the Heaven of the Stars, *Cœlum Stellatum*, or 8th circle, we must refer the cause of the elevation of the earth of our hemisphere to that. This Heaven of the Stars has at once unity in substance and multiplicity in its virtues or influences, as the poet himself sings:—

> "Il ciel, cui tanti lumi fanno bello,
> Dalla mente profonda che lui volve
> Prende l'image, e fassene suggello.
> E come l'alma dentro a vostra polve,
> Per differenti membra, e conformate
> A diverse potenzie, si risolve;
> Così l'intelligenzia sua bontate
> Multiplicata per le stelle spiega,
> Girando se sovra sua unitate."
> —"Paradiso," ii. 130 138.[1]

Dante further refers the elevation of our earth to that region of the Cœlum Stellatum which roofs over this uncovered earth; that is, that this elevating virtue or influence is in those stars which are in the region of the heaven, which is bounded by the equator and the circle which the pole of the zodiac describes around the pole of the world; "whether it elevate by way of attraction as the magnet draws the iron, or by way of impulsion, generating impelling vapours, as in certain mountains." A truly scientific and most suggestive remark!

---

[1] "The heaven, which lights so manifold make fair,
From the Intelligence profound, which turns it,
The image takes, and makes of it a seal.
And even as the soul within your dust
Through members different and accommodated
To faculties diverse expands itself,
So likewise this Intelligence diffuses
Its virtue *multiplied* among the stars,
Itself revolving on its *unity*."
"Paradiso," ii. 130-138, Longfellow's trans.

We may compare the last clause with those well-known lines of the "Inferno," in which is described how the earth, and likewise the mountain of Purgatory were formed when Lucifer fell from Heaven:—

> "Da questa parte cadde giù dal cielo;
> E la terra, che pria di qua si sporse,
> Per paura di lui fe del mar velo,
> E venne all'emisperio nostro: e forse
> Per fuggir lui, lasciò qui il luogo voto
> Quella ch'appar di qua, e su ricorse."
> —"Inferno," xxxiv. 121–126.[1]

But now it may be asked, Since that region of the heaven moveth circlewise, why did not this elevation happen circlewise? Because, Dante answers, the matter was not sufficient for so great an elevation. Then why was the elevation of the earth produced in our hemisphere rather than in the other? To this, says Dante, we must answer as Aristotle does (in "De Cœlo," book ii.) in answer to the question why the heavens move from east to west and not contrariwise, that such questions proceed either from much folly or from much presumption, because they are above our intellect. God made all things for the best, and when He said, "Congregentur aquæ in locum unum et appareat arida," then were the heavens virtuated to act and the earth potentiated to be passive.

"Let therefore men cease," cries Dante, "yea, cease from inquiring into those things which are above their intellect, and let them strive to the utmost of their power to raise themselves to things immortal and divine, and so leave those things which exceed their understanding. Let them listen to Job:—'Numquid vestigia Dei comprehendes, et omnipotentem usque ad perfectionem reperies.'—(Job xi. 7.) Let them hearken to the words of the Psalmist: 'Mirabilis facta est scientia tua; et me confortatus est, et non potero ad eam.'—(Ps. cxxxviii.) Let them hear Isaiah speaking in the person of God to man: 'Quam distant cœli a terra, tantum distant viæ meæ a viis vestris.'—(Is. lv. 9.) Let them hear the voice of the Apostle to the Romans: 'O altitudo divitiarum scientiæ et sapientiæ Dei! quam incomprehensibilia judicia ejus, et investigabiles viae ejus!'—(Rom. xi. 33.) Lastly, let them hearken to the very voice of the Creator, saying: 'Quo Ego vado, vos non potestis venire.'—(S. John vii. 34). And let these things suffice for the inquiry of the truth before us."

We may most fittingly compare this Dantesque passage with the close of Galileo Galilei's famous "Dialogo intorno ai due massimi sistemi del mondo, tolemaico e copernicano," which I here venture to translate:—

"*Simplicio.* If either of you were asked, If God in His infinite power and wisdom could confer upon the element of water the reciprocal movement which we perceive in it, in another way than by the moving of the vessel containing it, I know that you would answer, that He could have done so in many ways, even unimaginable by our intellect; whence I immediately conclude that, this being so, it would be excessive daring for any one to wish to limit and restrict the Divine power and wisdom to a particular phantasy of his own.

"*Salviati.* An admirable and truly angelical doctrine, to which very conformably answers that other divine doctrine, which, whilst it allows us to dispute about the constitution of the world, adds (perhaps in order that the exercise of human minds be not suppressed nor grow lazy) that we are not to find out the work of His hands. Let therefore the exercise permitted and ordained to us by God make us recognize and so much the more wonder at His greatness, as we find ourselves the less competent to penetrate into the profound abysses of His infinite wisdom.

"*Sagredo.* And this will serve for the last conclusion of our four days' argument."—Galileo Galilei, "Dialogo dei Massimi Sistemi, Giornata quarta."

Dante now briefly deals with the five arguments which he mentioned at the beginning of his treatise as the most important against his theory. These being made short work of, he concludes:—

"This philosophical question was determined by me, Dante Alighieri, the least of philosophers, beneath the sway of that invincible lord, Messer Cane Grande della Scala, for the holy Roman empire, in the illustrious city of Verona, in the church of S. Helena, and in the presence of all the Veronese clergy, save some few who, aflame with too much charity, do not admit the postulates of others, and through virtue of humility poor of the Holy Spirit, shun being present at their discourses, lest they may seem to approve their excellence.

"Now this was done in the year from the Nativity of our Lord Jesus Christ, 1320, on Sunday, which the Saviour injoined on us to venerate for His glorious Nativity and His wondrous Resurrection. The which day was the 7th from the ides of January and the 13th before the calends of February" (*i.e.* January 20).

I have dealt merely with the chief parts of this Dantesque dissertation. According to Signor A. Stoppani ("La questione dell' Acqua e della Terra di Dante Alighieri," in "opp. Lat. di Dante," ed. Giuliani, vol. ii.) there are nine truths relating to cosmology, presaged, affirmed, and in part demonstrated. These nine he makes out thus:—

(1) The moon the principal cause of tides.
(2) Equality of the sea's level.
(3) Centripetal force.
(4) Sphericity of the earth.
(5) Dry land simply protuberance of the earth's surface.
(6) Northern grouping together of the continents.
(7) Universal attraction.
(8) Elasticity of vapours a motive power.
(9) Heaving up of the continents.

Let me now add a tenth: A vague foreshadowing of our modern idea of chemical elements as distinct from those of Aristotle, or at least of homogeneous chemical bodies; "Corpora enim homogenea et simplicia sunt; homogenea, ut aurum depuratum; et corpora simplicia, ut ignis et terra."

EDMUND G. GARDNER.

Caius College, Cambridge.

MOROCCO.[1]

MOROCCO has a paradoxical place in the history of exploration; although the only part of Africa fully in sight from the shores of Europe, and dotted with one or two half European coast towns, its interior is more firmly closed to the traveller, sportsman, and missionary than the dense forests of the Congo, or even the shores of Lake Chad. The difficulties in the way are not physical, nor are they wholly political. They arise mainly from the deeply-rooted antagonism in race and creed between the inhabitants of Morocco and all Christendom—this quaint and semi-fossil phrase is still here a necessary and sufficient term. At this moment public attention is turned somewhat intently on the political conditions of the Oriental despotism which has so anomalously maintained itself to the west of our prime meridian. Hence the politician has a temporary interest in what would otherwise have appealed mainly to the geographer and man of science, the publication by the Royal Geographical Society of a "Supplementary Paper," the "Bibliography of Morocco." This is a work of splendid thoroughness, almost, if not quite, exhaustive in its list of 2243 titles, and made convenient for reference by two copious indexes of subjects and authors. But it is much more than a catalogue. Comments, judiciously brief, but in some cases of exceptional interest extending to a couple of pages, give information as to little-known authors, or record some striking circumstance in or concerning the books referred to. There is a specially-compiled map, and an introduction which is really an essay on the growth of knowledge regarding Morocco in European countries. With regard to the map, it is explained that only the coast-line has been surveyed. As to the interior :—

---

[1] "Upon this side he fell down out of heaven;
And all the land, that whilom here emerged,
For fear of him made of the sea a veil,
And came to our hemisphere; and peradventure
To flee from him, what on this side appears
Left the place vacant here, and back recoiled."
—"Inferno," xxxiv. 121-126, Longfellow's trans.

[1] "Bibliography of the Barbary States." Part IV. A Bibliography of Morocco from the earliest times to the end of 1891. By Lieut.-Col. Sir R. Lambert Playfair and Dr. Robert Brown.

"The best mapped districts are laid down solely from running *reconnaisances* or sketch-maps. Positions fixed by astronomical observations are few. Many wide areas have never been visited by any Europeans, and most of the Atlas is at this hour as little known as it was in the days of Leo Africanus. There are cities within a few hours' ride of Tangier, which no person capable of giving a correct account of his observations has visited; and there are others not much farther away, to attempt to enter which—Zarhoun, for example—would, were the intruder detected, be certain death. There is scarcely a river laid down with even approximate accuracy, and, not to enumerate more distant provinces, the entire Riff country, that bold *massif* which is familiar to the thousands who every year sail up and down the Mediterranean, is less explored than many regions in the centre of the continent."

The present population of Morocco is a puzzle almost as difficult, although on a smaller scale, as that of China. The authors of the Bibliography give 4,000,000 as an estimate, but the guesses of various authorities vary between $1\frac{1}{2}$ and 15 millions. The roads shown on the map are mere mule and camel tracks made by the feet of the pack-animals, unaided by any engineer. Ferries are rare, and, of course, bridges are unknown in the interior. The distribution of towns and villages is often at variance with the rules holding for civilised countries. The villages are built out of the way of the main tracks, because people never travel in Morocco for the good of the inhabitants, and it is safer to live off the path of the tax-collector and the Government official, who demands free food and quarters. The great number of place-names on the map of so thinly-peopled a country is due to the fact that the tombs of saints are such important landmarks that they must be indicated, even if only a few persons live beside them. "All the places beginning widh 'Sidi' (Lord, master) are either actually tombs or the tomb has formed, as in so many of our cathedral cities, the nucleus of the town or village." "Sok," another affix of frequent occurrence, means market-place, and many of the established sites for periodical fairs are uninhabited between the gatherings of people from far and near. Many of the place-names on the coast exist in two forms at least—the native word and its Portuguese or Spanish translation; Casablanca and Dar-el-beida (both meaning White house) for example. We regret that the authors did not see their way to lay down precise rules for the spelling of Moorish place-names, either by giving a standard transliteration of the Arabic, or a uniform phonetic system. Indeed, even in the introduction a few anomalous spellings are found, *e.g.* *Zarhoun* and *Zerhun*, *Moulai* and *Mowlai*.

The physical geography of Morocco appears to be changing, and the natural conditions of the country are less favourable for agriculture than they were a few centuries ago. The forests have been destroyed with such recklessness that the soil has been dried up and swept away in many places; there is evidence that the rainfall has diminished, lakes have dried, and rivers formerly navigable have become silted up, or alternate as dry tracts of stone and raging torrents.

In one respect alone—the enthusiastic Moslemism of its people—does Morocco show no sign of degeneration. Although the Moors can no longer seize and hold the Christian slaves, whose stories bulk so largely in the bibliography, their hatred and contempt towards "unbelievers" is in no sense abated. Into such a land no Europeans could penetrate far, except in the past as slaves, or now as official messengers of European Powers under special protection, jealously watched and prevented from studying places or people. The last serious attempt at scientific exploration—that of Mr. Joseph Thomson—was again and again almost stopped by the fanatical Kaids, and only his remarkable persistence and daring stratagems carried him as far as he reached. Such stratagems would hardly serve again, and for the present the exploration of the Atlas Mountains, with their half-guessed topography, imperfectly-known flora, and unsurveyed mineral wealth is at an end. The futility of disguise as an aid to exploration is fully proved in the records before us, where the ghastly fate of many who tried to pass as Moslems, and the unsatisfactory results obtained by others who escaped alive, are briefly told.

It seems to us that an attempt might well be made to open communications with fanatical Mohammedan countries either by explorers or diplomatic agents of the same faith, and there must be many amongst the educated Mohammedans of India who are well suited for such work. The religious beliefs of a people with whom belief and conduct are so closely related, must be taken into account in dealing with them, just as much as the physical features of a country. And as Arctic sailors have been proved to be the natural explorers in the Antarctic seas, Swiss mountaineers the safest pioneers on New Zealand glaciers, and Canadian boatmen the most expert in shooting the Nile cataracts, so Mohammedan envoys might be expected to make the most favourable impression on the people of Morocco or of the Mohammedan Sudan.

Sir Lambert Playfair and Dr. Brown deserve the heartiest thanks for completing their Bibliography of the Barbary States in such an admirable way, and we do not doubt that the work will be very widely consulted in the immediate future.

THE RATE OF EXPLOSION IN GASES.

THE following is an abstract of the Bakerian Lecture on "The Rate of Explosion in Gases," delivered before the Royal Society by Prof. Harold B. Dixon, on January 19:—

1. Berthelot's measurements of the rates of explosion of a number of gaseous mixtures have been confirmed. The rate of the explosion wave for each mixture is constant. It is independent of the diameter of the tube above a certain limit.

2. The rate is not absolutely independent of the initial temperature and pressure of the gases. With rise of temperature the rate falls; with rise of pressure the rate increases; but above a certain *crucial pressure* variations in pressure appear to have no effect.

3. In the explosion of carbonic oxide and oxygen in a long tube, the presence of steam has a marked effect on the rate. From measurements of the rate of explosion with different quantities of steam, the conclusion is drawn that at the high temperature of the explosion wave, as

well as in ordinary combustion, the oxidation of the carbonic oxide is effected by the interaction of the steam.

4. Inert gases are found to retard the explosion wave according to their volume and density. Within wide limits an excess of one of the combustible gases has the same retarding effect as an inert gas (of the same volume and density), which can take no part in the reaction.

5. Measurements of the rate of explosion can be employed for determining the course of some chemical changes.

In the explosion of a volatile carbon compound with oxygen, the gaseous carbon appears to burn first to carbonic oxide, and afterwards, if oxygen is present in excess, the carbonic oxide first formed burns to carbonic acid.

6. The theory proposed by Berthelot—that in the explosion wave the flame travels at the mean velocity of the products of combustion—although in agreement with the rates observed in a certain number of cases, does not account for the velocities found in other gaseous mixtures.

7. It seems probable that in the explosion wave—

(1) The gases are heated at *constant volume*, and not at *constant pressure*;

(2) Each layer of gas is raised in temperature *before* being burnt;

(3) The wave is propagated not only by the movements of the burnt molecules, but also by those of the heated but yet unburnt molecules;

(4) When the permanent volume of the gases is changed in the chemical reaction, an alteration of temperature is thereby caused which affects the velocity of the wave.

8. In a gas, of the mean density and temperature calculated on these assumptions, a sound wave would travel at a velocity which nearly agrees with the observed rate of explosion in those cases where the products of combustion are perfect gases.

9. With mixtures in which steam is formed, the rate of explosion falls below the calculated rate of the sound wave. But when such mixtures are largely diluted with an inert gas, the calculated and found velocities coincide. It seems reasonable to suppose that at the higher temperatures the lowering of the rate of explosion is brought about by the dissociation of the steam, or by an increase in its specific heat, or by both these causes.

10. The propagation of the explosion wave in gases must be accompanied by a very high pressure lasting for a very short time. The experiments of MM. Mallard and Le Chatelier, as well as the author's, show the presence of these fugitive pressures. It is possible that data for calculating the pressures produced may be derived from a knowledge of the densities of the unburnt gases and of their rates of explosion.

NOTES.

THE forty-sixth annual general meeting of the Institution of Mechanical Engineers will be held on Thursday evening and Friday evening, February 2 and 3, at 25, Great George Street, Westminster. The chair will be taken by the president, Dr. William Anderson, F.R.S., at half-past seven on each evening. The annual report of the council will be presented to the meeting on Thursday, and the annual election of the president, vice-presidents, and members of council, and the ordinary election of new members will take place on the same evening. The following papers will be read and discussed, as far as time permits:—Description of the Experimental Apparatus and Shaping Machine for Ship Models at the Admiralty Experiment Works, Haslar, by Mr. R. Edmund Froude, of Haslar (Thursday); description of the Pumping Engines and Water-Softening Machinery at the Southampton Water Works, by Mr. William Matthews, Waterworks Engineer (Friday).

PROF. CAYLEY, we are glad to learn, is now convalescent.

WE greatly regret to have to announce the death of Mr. H. F. Blanford, F.R.S. He died on Monday at the age of fifty-eight.

PROF. MICHAEL FOSTER, Sec.R.S., has been appointed Rede Lecturer at Cambridge for the present term. His Rede lecture will be delivered early in June.

THE Bill for the introduction of a standard time (mean solar time of the fifteenth meridian) was read a second time in the German Imperial Parliament on Monday. The measure was accepted without much discussion.

AN excellent report on technical education in London has been submitted to the London County Council by a special committee appointed to investigate the subject. The report was prepared by Mr. Llewellyn Smith, the committee's secretary, and displays a thorough grasp of the essential conditions of the problem. It is proposed that a Technical Instruction Board shall be appointed, and that it shall consist of some members of the Council, and of representatives of the School Board, the City and Guilds of London Institute, the City Parochial Charities, the Head Masters' Association, the National Union of Elementary Teachers, and the London Trades Council. The committee think that one-third of the amount derived from the beer and spirits duties should be handed over to this body for the provision of adequate technical instruction in all parts of London.

THE French Minister of the Interior has established at Marseilles, in connection with the university, an institute for botanical and geological research, and a museum. The director is Prof. Heckel, who, as well as a curator and a librarian, gives his services gratuitously.

IN the year 1793 was published Christian Konrad Sprengel's "Das entdeckte Geheimniss der Natur, im Bau und in der Befruchtung der Blumen," the work which first directed the attention of naturalists to the contrivances which, in many flowers, render self-pollination difficult, and promote the visits of insects to assist cross-pollination. The copper-plate illustrations of this work still maintain their character as among the best that have been published in this branch of science. Sprengel was in many respects a forerunner of Darwin, and centenaries have been celebrated on slighter grounds than the publication of this work.

THE chief characteristics of the weather during the past week have been its general mildness and dampness; the day temperatures have at times exceeded 50° in most parts of the kingdom, but at night slight frosts occurred towards the end of last week in Scotland and the south-eastern parts of England. The distribution of pressure has been complex, a series of depressions have passed over the coast of Norway from the westward, while an anticyclone lay over the south-western parts of our islands, the reading of the barometer in the south-west being about an inch higher than in the north of Scotland. The passage of the low-pressure systems in the north was accompanied by strong north-westerly winds and gales in Scotland, with hail or sleet in many places. Owing to the disappearance of the anticyclone from the continent, north-westerly winds became prevalent over western Europe, and a rapid rise of temperature occurred there, amounting to 30° in Germany between the 20th and 21st instant. During the last few days fresh depressions have approached our north-western coasts, with increasing winds from the south-west, and a continuance of mild, unsettled weather appeared probable. The *Weekly Weather Report* shows that for the week ending the 21st instant there was a large deficiency of rainfall in the west of Scotland, south-west of England, and south of Ireland. The percentage of possible duration of sunshine ranged from 28 in the south-west of England to 7 in the south of England and to 3 in the north of Scotland.

THE *Repertorium für Meteorologie*, vol. xv. recently issued by the Imperial Academy of Sciences of St. Petersburg, contains a discussion by P. A. Müller, of the Ekaterinburg Observatory, at the foot of the Ural Mountains, in the Government of Perm, on the question of the evaporation from a snow surface. Several writers, among whom are Drs. Brückner and Woeikof, differ in opinion as to whether the evaporation from a snow surface exceeds the condensation of the aqueous vapour of the air immediately above it. The method generally adopted for the decision of the question is to find whether the temperature of the snow surface is above or below the dew-point of the surrounding air; in one case there would be evaporation, and in the other condensation. The paper occupies forty-seven small folio pages, and the observations were made hourly from December 21, 1890, to February 28, 1891. The result of the investigation shows that according to the temperatures of the dew-point and of the surface of the snow, the evaporation of the snow greatly exceeds the condensation of the aqueous vapour, for the condensation occurred at only 27 per cent. while the evaporation occurred at 73 per cent. of the hourly observations.

PROF. FLINDERS PETRIE, to whose introductory lecture at University College, Gower Street, we referred last week, delivered on Saturday the first of his regular course of lectures on the Edwards Foundation. He said the Egypt of the early monuments was a mere strip of a few miles wide of green, amid boundless deserts, and beneath a sky of the greatest brilliancy; a land of extreme contrasts of light and shadow, of life and death. These conditions were reflected in the art. On the one hand was the most massive and overwhelming construction, and, on the other, the most delicate and detailed reliefs. On the one hand, the most sublime and stolid statuary; on the other, the course and accidents of daily life freely treated. On the one hand, masses of smooth buildings that far outdo the native hills on which they stand, gaunt and bare, and, on the other, the vivid and rich colouring in the interiors. In consequence of the climate also Egypt is a land of great simplicity of life, and simplicity is especially the characteristic of the oldest Egyptian buildings. Speaking of the early Egyptian statues, Prof. Petrie said that the race represented by them appears as "one of the noblest that ever existed."

AT Leeds, on Monday, Lord Playfair presided at a public dinner, held in support of the Yorkshire College. In proposing the principal toast—"The Yorkshire College"—he spoke of the efforts made half a century ago to secure for science the place which rightly belongs to it in the educational system. He was glad, he said, that these efforts had met with a temporary resistance, because if the Universities had at once yielded there would have been no colleges now in our great provincial towns. The colleges, he thought, were adapting themselves rapidly and well, upon the whole, to the genius of their several localities. Of the Yorkshire College he said that she had fitted herself for the liberal culture and life-work of a great industrial centre. "No doubt her technical courses are peculiar. Actual laboratories for spinning, for dyeing, for tanning, for engineering, are novel adjuncts to a college. What does it mean? That you are trying to strengthen and embellish industrial pursuits, as the Universities acted upon the professions when they were obliged to include them. Surely a great town like Leeds is right when it imbues its producers with intellectual knowledge, as well as with technical expertness. Such men in future carve out industrial professions for themselves, and illumine them by appropriate culture."

THE interesting address lately delivered by Sir Henry Roscoe on the occasion of the prize distribution at the Birmingham Municipal Technical School has now been issued separately. He describes the report of the first year's work as "more than encouraging." Speaking of the building which is to be erected for technical training at Birmingham, he says:—"You in Birmingham have, in my judgment, taken the right course. You are not going to squander your money by using it for a thousand different purposes. You are, I hope, going to do a good thing, and a big thing, in building and equipping a really great institution, worthy of your city and of your well-earned renown as being foremost amongst our towns in educational matters. You will have a place of higher technical instruction to which all the Midlands will look up. It will be the gathering ground for all the youthful talent of the busy millions of the district. It will be here that the future Faradays, and Priestleys, and Watts will get that sound though elementary scientific training which will enable them to pursue that training to its highest point at the Mason College here, or in other colleges elsewhere, which may in the end make both them and their country great."

THE new technical schools connected with University College, Nottingham, which were formally opened the other day, promise to be of immense service, not only to Nottingham itself, but to the wide district of which it is the educational centre. A remarkably clear description of the buildings, with plans, is given in a pamphlet prepared for the ceremonial opening. The pamphlet also includes an interesting summary of the facts relating to the history of the Nottingham College and its technical department.

MR. C. F. JURITZ, Senior Analyst in the Department of Lands, Mines, and Agriculture, Cape Colony, announces in the *Agricultural Journal*, issued by the Department, that a comprehensive series of investigations with reference to the chemical composition of the various soils of the colony is about to be undertaken. The samples of soil are to be collected by one of the officers of the analytical branch of the Department. In the first instance the southern part of the Malmesbury district will be visited, and soils will be taken from several localities representative (*a*) of primary and (*b*) of alluvial soils belonging to the Malmesbury beds of clay slate. Mr. Juritz proposes next to collect soils from the more northerly portion of the same district, in the vicinity of Hopefield, for instance, after which the Caledon district will be taken in hand. These analyses when completed will afford, he points out, an insight into the general composition of the clay slate soils, lying around the south-western coast of the Colony between Donkin's and Mossel Bays. The Government of Cape Colony look upon the proposals that have been made as "a move in the right direction," and have promised their warmest support.

MR. KEDARNATH BASU, describing in *Science* some relics of primitive fashions in India, says he does not see the same profusion as he saw ten or twelve years ago, of tattoo-marks and red-ochre or red oxide of lead (*sindur*) over the forehead and crown among the women of Bengal. The rapid progress of female education and the consequent refinement in æsthetic taste are, he says, the causes of the decline of this rude and savage adornment. The people of Behar, the North-western provinces, and other districts, however, still cling to these remnants of savagery. The up-country women, besides tatooing their bodies and painting the head with red paint, bore the lower lobes of their ears, and insert big and heavy wooden cylindrical plugs, which almost sever the lobes from the ears. The plugs are sometimes as big as two inches in length with a diameter of an inch and a half, and as much as two ounces in weight. These heavy plugs pull down the lobes of the ears as far as the shoulders, and give the wearers a hideous look.

MR. F. J. BLISS contributes to the new "Quarterly Statement" of the Palestine Exploration Fund a most interesting report on the excavations at Tell-el-Hesy during the spring season of 1892. Speaking of the now famous tablet discovered in the course of these excavations, he says:—"On Monday, May 14, ten days before we closed the work, I was in my tent at noon with Ibrahim Effendi, when my foreman Yusif came in with a small coffee-coloured stone in his hand. It seemed to be curiously notched on both sides and three edges, but was so filled in with earth that it was not till I carefully brushed it clean that the precious cuneiform letters were apparent. Then I thought of a day, more than a year before, when I sat in Petrie's tent at the pyramid of Meydûm, with Prof. Sayce. He told me that I was to find cuneiform tablets in the Tell-el-Hesy, which as yet I had never seen; and gazing across the green valley of the slow, brown Nile, and across the yellow desert beyond, he seemed to pierce to the core, with the eye of faith, the far away Amorite mound. As for me, I saw no tablets, but I seemed to be seeing one who saw them!" Mr. Bliss also notes that the discovery was a triumphant vindication of Mr. Flinders Petrie's chronology—established, not by even a single dated object, but by pottery, mostly plain and unpainted. It is announced in the "Quarterly Statement" that the excavations at Tell-el-Hesy are now being vigorously carried on by Mr. Bliss, who has recovered from his serious illness.

IT seems that in Yucatan and Central America, as in Egypt and other countries, ancient monuments are held in small respect by certain classes of travellers. According to Mr. M. H. Saville, assistant in the Peabody Museum, who writes on the subject in *Science*, enormous damage is being done to many of the most interesting antiquities in these regions. The magnificent "House of the Governor" in Uxmal, described as probably the grandest building now standing in Yucatan, is almost covered with names on the front and on the cemented walls inside. These names are painted in black, blue, and red, and among them are the names of men widely known in the scientific world. The "House of the Dwarfs" in the same city has suffered in like manner, and many of the sculptures which have fallen from the buildings in Uxmal have been wilfully broken. In Copan, when the Peabody Museum Honduras Expedition compared the condition of the "Idols" to-day with the photographs taken by Mr. A. P. Maudslay seven years ago, it was found that during that time some of the very finest sculptures had been disfigured by blows from machetes and other instruments. The Stela given as a frontispiece in Stephens' "Incidents of Travel in Central America," vol. i., has been much marred by some one who has broken off several ornaments and a beautiful medallion face from the northern side. One of the faces and several noses have been broken off from the sitting figures on the altar figured by Stephens in the same volume, opposite page 142; and on some of the idols and altars names have been carved. While excavating in one of the chambers of the Main Structure, members of the Expedition uncovered a beautiful hieroglyphic step, but before they had time to secure a photograph of it, some visitor improved the opportunity while no one was about to break off one of the letters. In Quirigua a small statue, discovered by Mr. Maudslay and removed by him to a small house near the rancho of Quirigua, had the head and one of the arms broken from it during the interval between two visits. This statue was of the highest importance, as it very much resembled the celebrated "Chaac-mol" now in the Mexican Museum, but discovered by Le Plongeon at Chichen Itza. Much mischief is also done by natives, who think nothing of tearing down ancient structures in order to provide themselves with building materials. The authorities of the Peabody Museum, to whom the care of the antiquities of Honduras has been granted for a period of ten years, deserve much credit for the efforts they make to cope with the evil. They have caused a wall to be built round the principal remains in Copan, and a keeper has been placed in charge with strict orders to allow nothing to be destroyed or carried away.

WHAT is the true Shamrock? Most Irishmen are probably of opinion that they can answer the question correctly, but unfortunately they do not all give the same reply. Mr. Nathaniel Colgan, who has been investigating the subject, collected thirteen specimens from the following eleven counties—Derry, Antrim, Armagh, Mayo, Clare, Cork, Wexford, Wicklow, Carlow, Queen's County, and Roscommon. Shamrocks were thus secured from northern, southern, eastern, western, and central Ireland, Mr. Colgan's correspondents in the various counties taking pains to have each sample selected by a native of experience who professed to know the genuine plant. All the specimens were planted and carefully labelled with their places of origin, and flowering within some two months later gave the following results: eight of the specimens turned out to be *Trifolium minus* of Smith, and the remaining five *Trifolium repens* of Linnæus. Cork, Derry, Wicklow, Queen's County, Clare, and Wexford declared for *Trifolium minus*; Mayo, Antrim, and Roscommon for *Trifolium repens*; and Armagh and Carlow, each of which had sent two specimens, were divided on the question, one district in each county giving *T. repens*, while the other gave *T. minus*. These results are set forth by Mr. Colgan in an interesting paper in the first volume of the *Irish Naturalist*, to which we referred last week. Elsewhere in the same volume Mr. R. L. Praeger suggests that authentic specimens of shamrock should be obtained from every county in Ireland, and he adds that he has no doubt Mr. F. W. Moore would gladly grow them at Glasnevin Gardens, if Mr. Colgan did not care to undertake so large an order. Mr. Praeger notes that in his own district, North Down, *Trifolium minus* is always regarded as the true shamrock, but that a luxuriant specimen, or one in flower, is generally discarded as an impostor.

THE waters of the Great Salt Lake, Utah, are known to vary in salinity at different times. Dr. Waller, of Columbia College, gives the results of his recent determination of the dissolved salts in the *School of Mines Quarterly*. A comparison of his results with those obtained by Gale, Allen, Bassett, and others, shows a constant change of salinity, and a closer examination reveals a variation from place to place. This is due to local differences in the amount of evaporation, and to the influx of water, fresh or saline, in many cases from subterranean springs which give no indication of their presence. For some of the constituents the water is nearly at saturation point, and differences of temperature are also apt to cause slight differences of composition. The presence of lithium and bromine strengthens Captain Bonneville's conclusions with regard to the basin of the ancient lake called after his name, and now represented by the Great Salt Lake and its lesser neighbours. The benches of sand and gravel seen high up on the flanks of the Wahsatch mountains and the Oquirrh range indicate the eastern and western shores of the old lake, whose waters must have covered an area equal to that of Lake Huron, or ten times that of the Great Salt Lake. Successive lowerings of level finally cut off its outlet to the north, by which it used to flow into the Pacific Ocean.

A BEAUTIFUL optical phenomenon, which has not yet been satisfactorily explained, is described by M. F. Folie in the *Bulletin* of the Belgian Academy. It was observed about a mile from Zermatt on August 13 at 8.30 a.m. "On our right, towards the east, on the steep flanks of the mountains which enclose the valley of the Viège, rose a group of fir trees, the highest of which projected themselves against the azure of the sky, at a height of 500 m. above the road. Whilst I was botanising my son exclaimed: 'Come and look: the firs are as if covered with hoar-frost!' We paid the most scrupulous attention to the phenomenon. To make sure that we were not misled by an illusion we made various observations, both with the naked eye and with an excellent opera-glass." It was observed that not only the distant trees, but those lining the road, glittered in a silvery light, which seemed to belong to the trees themselves, and that the insects and birds playing round the branches were bathed in the same light, forming an aureole round the tops of the trees, somewhat resembling the light effects observed in the Blue Grotto. It is suggested that the light was reflected from the snow. Since it disappeared as soon as the sun rose above the hill, and has never been seen except in the presence of snow, this explanation appears plausible, but it is highly desirable that further and more detailed observations should be made of this *spectacle féerique.*

THE Tasmanian Official Record is henceforth to be issued tri-annually instead of annually, and a handbook has been issued to take its place during the intervening years. This handbook (which is described on the title-page as "for the year 1892") contains a brief epitome of the historical portion of the Official Record, and summarises in a convenient form the more important statistical information contained in the detailed tables of the last volume of the general statistics of the colony.

MESSRS. ASHER AND CO. will publish shortly an English translation of the "Recollections of the Life of the late Werner von Siemens," the well-known electrician, and brother of Sir William Siemens. Two editions of the German original, published in December last, were issued in the course of a few weeks.

THE course of four winter lectures in connection with the London Geological Field Class will this year be delivered by Prof. H. G. Seeley, F.R.S., on Tuesday evenings, at the Memorial Hall, Farringdon Street, the subject being "The Fossil Reptiles of the Thames Basin." All particulars may be had of the Hon. Sec. Mr. J. H. Hodd, 30 and 31, Hatton Garden, E.C.

THE bacterial purification which takes place in a river during its flow has been recently attributed in part to the process of sedimentation which the micro-organisms in the water undergo, but it would seem that yet another factor must be taken into account. Buchner, in some investigations which he has recently published ("Ueber den Einfluss des Lichtes auf Bakterien," *Centralblatt für Bakteriologie*, vol. 11, 1892, also vol. 12, p. 217) shows that this diminution of the numbers present may be also assisted by the deleterious action which light exercises upon certain micro-organisms. A systematic series of experiments was made by introducing typhoid bacilli, *B. coli communis*, *B. pyocyaneus*, Koch's cholera spirilla, also various putrefactive bacteria, into vessels containing sterilized and non-sterilized ordinary drinking water. As a control, in each experiment one vessel thus infected was exposed to light, whilst a second was kept under precisely similar conditions, with the exception of its being covered up with black paper, by means of which every particle of light was excluded. The uniform result obtained in all these experiments was that light exercised a most powerful bactericidal action upon the bacteria in the water under observation. For example, in one water in which at the commencement of the experiment 100,000 germs of *B. coli communis* were present in a c.c., after one hour's exposure to direct sunlight *none* were discoverable, whilst in the darkened control flask during the same period a slight increase in the numbers present had taken place. Even the addition of culture fluid to the flasks exposed to sunlight could not impair in the least the bactericidal properties of the sun's rays. In the flasks exposed to diffused daylight the action was less violent but still a marked diminution was observed. In his later experiments Buchner has employed agar-agar, mixing a large quantity of particular organisms, pathogenic and others, with this material in shallow covered dishes and then exposing them to the action of light and noting its effect upon the development of the colonies. For this purpose strips of black paper cut in any shape (in the particular dish photographed by Buchner letters were used) were attached outside to the bottom of the dish, which was then turned upwards and exposed to direct sunlight for one to one and a half hours and to diffused daylight for five hours. After this the dish was incubated in a dark cupboard. At the end of twenty-four hours the form of the letters fastened to the bottom of the dish was sharply defined, the development of the colonies having *taken place in no part of the dish, except in those portions covered by the black letters.* Some interesting experiments on the same subject have also recently been made by Kotljar (*Centralblatt für Bakteriologie*, December 20, 1892). In the course of these investigations the author found that of the coloured rays of the spectrum the red favoured the growth of those bacteria experimented with, whilst the violet rays acted prejudicially, although less so than the white rays. The exceedingly interesting observation was made that the violet rays actually favoured the sporulation of the *Bac. pseudo anthracis.*

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus* ♂) from India, presented by Mr. A. Sandbach; a Triton Cockatoo (*Cacatua triton*) from New Guinea, presented by Mr. Arthur Harter; a Gannet (*Sula bassana*) British, presented by Mr. F. W. Ward; two Tuatera Lizards (*Sphenodon punctatus*) from New Zealand, presented by Mr. W. H. Purvis; two Wanderoo Monkeys (*Macacus silenus*) from the Malabar Coast; a Straw-necked Ibis (*Carphibis spinicollis*) from Australia; four Snow Buntings (*Plectrophanes nivalis*); six Wild Ducks (*Anas boschas*, 3 ♂ 3 ♀) British, purchased; a Meadow Bunting (*Emberiza cia*) European, received in exchange; two Shaw's Gerbilles (*Gerbillus shawi*) born in the Gardens.

OUR ASTRONOMICAL COLUMN.

COMET HOLMES.—*Edinburgh Circular*, No. 37, announces that Palisa, telegraphing from Vienna, states that Comet Holmes now resembles an 8 m. star with a nebulous envelope 20″ of arc in diameter.

A further observation made by Prof. Schur in Göttingen on January 19 showed that the nucleus was of the 10th magnitude, and could not be considered at all brighter than that magnitude. For the latter observation the air, as regards clearness, was all that could have been desired.

At South Kensington, on January 18, the comet was observed as a hazy star and estimated to be about the 8th magnitude.

The following ephemeris is that given by Schulhof:—

Date.		R.A. app.			Decl. app.		
		h.	m.	s.	°	′	″
Jan.	26	1	35	33·0	+33	42	3
	27		36	58·7		42	51
	28		38	25·1		43	44
	29		39	52·1		44	43
	30		41	19·8		45	46
	31		42	48·1		46	55
Feb.	1		44	17·0		48	8
	2	1	45	46·5	33	49	26

On January 30 the comet will lie very nearly between β Andromedæ and β Trianguli, about one-third of the distance from the latter star.

COMET BROOKS (NOVEMBER 19, 1892).—The following ephemeris of Comet Brooks is due to Ristenpart, and is given in *Astronomische Nachrichten*, No. 3142:—

1893.	R.A. (app.) h. m. s.	Decl. (app.) ° ′	Log *r*.	Log Δ.	Br.
Jan. 26	23 35 8	+40 34·3	0·0921	0·0471	2·94
27	38 53	39 34·1			
28	42 22	38 36·8	0·0950	0·0688	2·62
29	45 37	37 42·2			
30	48 40	36 50·2	0·0981	0·0898	2·35
31	51 32	36 0·5			
Feb. 1	54 14	35 13·1	0·1015	0·1101	2·11
2	23 56 48	34 27·7			

This comet, which will be found to be in the constellation of Andromeda, will lie about 3½° to the south of *i* Andromedæ on January 27.

PHOTOGRAPHIC ABSORPTION OF OUR ATMOSPHERE.—The question of the degree with which our atmosphere absorbs photographic rays has become very important owing to the adoption of photography, so that any work enlightening us on this subject is anxiously listened to. Prof. Schaeberle, who has been making investigations in this direction, has just completed a memoir which is being published by the University of California, but in the meanwhile he has issued a table setting forth simply the final results. The absorption in the following table is expressed in photographic magnitudes, and must be added to the unknown atmospheric absorption at the zenith.

HARVARD COLLEGE OBSERVATORY.—The forty-seventh annual report of this Observatory, by Prof. Pickering, opens with a reference to the death of Mr. George B. Clark, to whose "genius for mechanical devices, indomitable perseverance, and devotion to the interests of the observatory, we are indebted for the success of many of our most useful instruments." Of the most important matters mentioned in the report are the permanent establishment of an observing station in South America, where the unsteadiness of the air is for the most part eliminated, the construction of a suitable building for the housing of photographs and the approaching completion of the Bruce photographic telescope. The work done with the various instruments during this period has been considerable. With regard to the Draper telescope, as many as 2777 photographs have been taken, while those taken with the Bache instrument number nearly 2000. The Boyden department, which is situated at Arequipa, in Peru, has been making great progress, the results of which have been frequently inserted in *Astronomy and Astrophysics*. The eight surfaces of the objective of the Bruce telescope have, as Prof. Pickering informs us, been ground and polished, and the results up to the present, according to tests made on a star, are very satisfactory. This instrument, when finished, is destined fo. the Arequipa station.

SOLAR OBSERVATIONS AT ROME.—Prof. Tacchini has issued the results of the observations made with regard to the distribution in latitude of the solar phenomena at the Royal Observatory during the third semester in 1892. From the tabulated statement which he gives the following facts may be gathered.

With regard to the eruptions, these phenomena seem to be quite local to the equatorial regions, the relative frequency being 0·667 and 0·333 for the north and south latitudes respectively. The spots, faculæ, and eruptions have their maxima nearly at the same distance from the equator both north and south, the zones being (± 20°, ± 30°), but the maxima for the prominences extend further north, about latitudes 60° north and south. Prof. Tacchini remarks that in the equatorial zone (+20°–20°), where the maxima of faculæ, spots, and eruptions are observed, a feeble relative frequency in the prominences is noted, which shows us that we must consider a large number of prominences as the result of conditions "bien différentes par rapport à celles qui déterminent la production des taches dans la photosphère," whilst the prominences are formed simply in the solar atmosphere. As a case in point, he mentions an observation made on August 1 of last year, of a cloud which, starting at a distance of 264″, rose to 364″ without any corresponding alteration at the surface.

THE TOTAL SOLAR ECLIPSE, APRIL 15–16, 1893.—Writing to M. Flammarion about the scientific expedition sent by the Brazilian Government to study the region of the central plateau and to select a site for the proposed new capital, Dr. Cruls, the Director of the Observatory at Rio de Janeiro, adds the following note:—"About the total eclipse of April 16. Will France send any one to observe it? I beg you to make known through the *Review* (*L'Astronomie*) that the Brazilian Government is willing to send a warship to Ceara, on which foreign astronomers who wished to observe the phenomenon could find a passage."

GEOGRAPHICAL NOTES.

A CHANGE has been made in the arrangements for the expedition to Lake Rudolf referred to on p. 235, vol. xlvii. The expedition is to travel by the Tana river instead of the Juba, although its ultimate destination is the same, and Lieutenant Villiers, instead of accompanying it, has joined Sir Gerald Portal's mission to Uganda.

MR. H. J. MACKINDER, M.A., Reader in Geography at Oxford, delivered the first of a course of ten educational lectures, under the auspices of the Royal Geographical Society, on the relation of geography to history, on the 20th inst. The attendance was largely composed of teachers and University Extension students, to whom special terms were offered. The lecturer treated of "the Theatre of History," tracing the development of accurate geographical knowledge from the earliest times in a series of brilliant generalisations. He dwelt upon the contrast between the knowledge of early Greek geographers regarding the true shape of the earth, and their habitual representation of the regions known to them in a circular form. In the middle ages, amongst the half-learned, the map of the known world was elevated to the highest place, the figure of the globe was forgotten, and the doctrine of a flat earth gained currency. At the geographical *renaissance* the map was adapted once more to the sphere, and the discoveries of Columbus and his contemporaries resulted directly.

THE suggestion of Mr. Joseph Thomson to bestow the name of Livingstonia (vol. xlvii. p. 160) on the British sphere of influence north of the Zambesi, in spite of its singular propriety, has, we fear, failed to convince the authorities in charge of the region, who, it appears, have decided to adopt the cumbrous and scarcely accurate title of British Central Africa.

M. MIZON'S second expedition to Adamawa has been stopped on the Benué by the breakdown of his steamers, and the sudden falling of the water, he being left without means of progress about two-thirds of the way between Lukoja and Yola.

THE French flag has been formally hoisted on the little islands of St. Paul and New Amsterdam in the South Indian Ocean, midway between the Cape of Good Hope and Australia. St. Paul is an interesting instance of a volcanic island, the extinct crater of which forms a wide sheltered harbour communicating with the sea by means of a single narrow channel. It was one of the French stations for observing the transit of Venus in 1874. French fishermen from Reunion had practically taken possession of the islands in the early part of the century, but the fishing-grounds have long been abandoned.

MR. B. V. DARBISHIRE, M.A. (Oxon.), has been appointed Cartographer to the Royal Geographical Society. He has had the advantage of preliminary training in Germany, and under the Reader in Geography at Oxford.

THE APPROACHING ECLIPSE OF THE SUN, APRIL 16, 1893.[1]

I HAD the honour, two and a half years ago, of describing to you the total eclipse of the sun of December 22, 1889, which I had been to observe in the Salut Isles, French Guiana. In spite of very unfavourable atmospheric conditions I was then able to take some photographs of the phenomena and to measure the actinic intensity of the corona. Two years previously I had been to Russia to observe the eclipse of August 18, 1887, but the bad weather prevented any observations. If these expeditions did not succeed as well as I had hoped, they were at least useful in showing me all the difficulties to be met with in such undertakings, and of convincing me that if one wishes to thoroughly avail one's self of the precious moments during which the eclipse lasts, it is necessary to gain a large experience of these phenomena by omitting no opportunity of observing them, and by making a speciality of these expeditions. Therefore, after the eclipse of 1889 I determined to go to observe the following eclipse, that of the 16th of next April.

---

[1] Address to the Astronomical Society of France, on November 2, 1892, by M. De la Baume Pluvinel, translated by A. Taylor.

This time the phenomenon is visible under particularly favourable conditions. On the African coast to the south of Dakar, where the expedition sent by the Bureau des Longitudes will observe, and where I also propose to instal myself, the duration of totality is four minutes thirteen seconds. Moreover, a very important consideration is that we are certain of fine weather. At a time when expeditions are being organised in every country in view of this astronomical event, I think it will be useful to draw your attention to the chief questions which should be the object of astronomical study during the next eclipse.

You are aware that the passing of the moon before the sun has the inestimable advantage of allowing us to see the circumsolar regions which, under ordinary circumstances, because of their faint light are lost in the general illumination of our atmosphere. The regions thus revealed consist of a layer in immediate contact with the sun, the chromosphere, in which are the rosy flames which form the protuberances; and a more or less extensive luminous aureole, the corona. But since the celebrated eclipse of 1868, which marks an epoch in the history of solar physics, we are able, thanks to the great discovery of Messrs. Janssen and Lockyer, to study the protuberances at any time, and consequently it is only to the corona that the attention of astronomers turns during total eclipses.

An invariable part of the day's programme is the study of the structure of the corona, and the luminous intensity of its various parts. We need to have recourse to photography for trustworthy evidence as to this, for photography alone can give a faithful representation of the phenomena; even the best drawings always leave much to be desired. Indeed, it is impossible in the space of a few minutes to exactly represent a nebulous mass as complicated as the corona, and without any definite outlines. We can judge of the difficulty presented by the drawing of the corona, by remembering that even the most skilful draughtsmen have never yet been able to give us similar drawings of the great Orion nebula, although this may be studied at leisure. The brilliancy of the corona varies in intensity so much from one eclipse to another, that it is difficult to determine beforehand the length of exposure needed with given apparatus to obtain as satisfactory a representation of the phenomenon as possible. Moreover, the different parts of the corona differ in brilliancy, so that when the photographic action is sufficient to give a good image of the middle part, the lower portions which form the interior corona are over-exposed, while the extreme limits of the aureole are not reproduced. To satisfy all the conditions it is necessary to take several photographs with different exposures.

To advantageously discuss the results obtained it is very important that astronomers should place upon each plate a uniform scale to measure the intensity of the photographic action upon it. This intensity is equal to the product of three factors; the effectiveness of the object glass, the length of exposure, and the sensitiveness of the plate. If we indicate the useful diameter of the object glass by a and the focus by f, the effectiveness, defined by the international congress of photography, is $100\frac{a^2}{f^2}$. If we take plates of gelatinobromide of silver of normal sensitiveness as our unit, and let t be the length of exposure in seconds, we have the following formula to express the photographic action:—$100\frac{a^2}{f^2}t$. In working with wet collodion plates it is necessary to multiply this expression by $\frac{1}{30}$, and with plates of dry collodion it must be multiplied by $\frac{1}{300}$. The first photographs of the corona, taken with wet collodion, from 1868 to 1878, were obtained with a photographic action not greater than 2. Later, thanks to rapid plates, much greater action could be obtained. Thus in 1883 a photograph obtained by M. Janssen had received a photographic action equal to 918. On the negative thus obtained, the corona extended to between 30′ and 40′ from the limb of the moon, but on the other hand, details of the parts near the sun were completely wanting.

We might ask whether by still further increasing the photographic action we should also extend the limits of the corona? Certainly not! for if the photographic action is too intense, the faint contrast between the extreme parts of the corona and the more or less illuminated sky is no longer appreciable on the negative. We know, indeed, that if we wish to produce the maximum contrast between two half tones we must only use just enough light for the faintest of the half-tones to give a perceptible image. In America, Mr. Burnham has been engaged in determining the maximum length of exposure necessary to obtain the best representation of the corona, and he has made experiments on this subject by photographing the moon and white clouds on a faintly lighted sky.

In 1889, at the Salut Isles, I used five instruments, giving photographic actions varying from 185 to 13, but, doubtless on account of the peculiarly intense illumination of the atmosphere due to the short duration of totality, and the great abundance of water vapour in the atmosphere, the most satisfactory negative was that corresponding to a photographic action of 30. It is very probable that an equally good result might have been obtained with much less photographic action. Mr. Barnard, to whom we owe the best photographs of the eclipse of January 1, 1889, worked with a photographic action equal to 0·58. This result proves that with the sensitive plates now in use it should be possible to obtain good images of the corona on a large scale by using secondary magnifiers to increase the size of the image given by the object glass. In any case we can employ object glasses of two or three metres focal length, which would give images sufficiently large to show all the details of the corona without having resort to enlargement of the plates. Nevertheless, in spite of the use of a long focus, the instrument must remain luminous enough for the time of exposure to be short. The displacements of the image on the plate, caused by the imperfect adjustment of the equatorial mounting, or by an irregularity in the clockwork movement, or by the movement of the sun in declination are thus rendered inappreciable.

The photographs, when obtained, should be examined from the following different points of view. First of all we wish to find if the corona, which will be observed in the month of April, 1893, at a period of great solar activity, and at an epoch when the south pole of the sun is projected on the visible part of its disc, resembles, as we have every reason to think it does, the corona of 1883, which was studied under the same conditions. A great resemblance between the forms of the corona in 1889 and 1878, at the periods of minimum sun-spots, has already been noted, and if it can be established that the corona, seen under similar conditions, presents the same appearance, it will be proved that the diversity of appearance hitherto noticed depends solely upon the state of agitation of the solar surface, and the position of the observer with respect to the solar equator.

If the corona should present an axis of symmetry it must be ascertained whether the poles of this axis coincide with the poles of the axis of rotation of the sun; or if, as is more usually the case, the poles of the corona are inclined at some degrees from the poles of the sun, thus resembling the position of the magnetic poles of the earth with regard to its geographical poles. If the corona shares in the movement of rotation of the sun, it must be the same with its axis of symmetry, and therefore if we once observe the northern pole of the corona to the east of the northern pole of the sun, we ought to find it after an uneven number of half-revolutions, of the sun to the west of the north pole of the sun. To ascertain if this is so or not, it is of the greatest importance to know exactly the orientation of the images upon the photographic plates. The most exact and simple method to orient the images is to place the photographic apparatus in the position which it occupied at the moment of the phenomena, and, in the night, to photograph the trails which the stars leave in passing across the field of the lens.

If the photographs should show the structure of the corona clearly, we shall be able to study the form of those luminous rays which we notice at the poles of the sun, and of those curvilinear structures which seem to extend from the middle latitudes of the sun. The study of the curvature of these structures will be very useful in verifying the exactness of one of the most favoured theories of the corona, which explains the phenomena by supposing that matter is thrown out by the sun normally at its surface, and that its projection is turned on one side by the rotation of the sun. Mr. Schaeberle, of the Lick Observatory, has mathematically studied this theory, and on applying it to eclipses already observed, has been able to report that the curvature of the structures has always conformed with the theory.

We must also examine the photographs taken with the longest exposure, to determine whether the dark parts which sometimes separate the luminous structures, and which we can trace to the base of the corona, are entirely destitute of light. The existence of these *rifts*, as the English call them, is difficult to explain, if we suppose that the coronal atmosphere entirely surrounds the sun, for in that case we should always see, projected on the plane perpendicular to the line of sight, the coronal matter all round the sun. According to Prof. Hastings, the presence of these rifts is a confirmation of his theory which ascribes the corona to diffraction, and not to the existence of a material mass.

Is the aspect of the corona quickly modified, or are the changes which we notice from one eclipse to another effected slowly? Hitherto we have never proved the difference between the photographs of the same eclipse taken at several hours' interval, and at stations very distant from each other. The English astronomers thought of testing this question in December, 1889, and the two English expeditions sent, one to the Salut Isles, and the other to the west coast of Africa, were furnished with photographic outfits as identical as possible, in order to obtain, at an interval of two and a half hours, comparable negatives of the corona. Unfortunately the complete failure of the expedition on the African coast did not permit the carrying out of this programme; otherwise it is very probable they would have proved no sensible difference between the negatives at the two stations, for photographs show that the corona of December 22, 1889, was almost identical with that of January 1 of the same year. We may say, then, that during the year 1889, a year of quietude on the solar surface, the appearance of the corona did not appreciably change.

However, the experiment attempted by the English expeditions needs to be repeated; if not to study the internal movements of the corona, to obtain identical photographs at two different angles, which would enable us, with the aid of the stereoscope, to judge of the *relief* of the corona.

Photographs of a total eclipse will not only inform us as to the structure of the corona, but will permit us to measure its actinic brightness. We can estimate the relative intensity of different parts of the corona by superposing several photographs, made on the same scale, but obtained with very different photographic actions. The outlines of each image would give lines of equal actinic intensity of the corona. The absolute intensity may be measured by comparing the opacity of the image on the plate with the opacities produced on the same plate from a source of standard light. For this purpose the plates destined for photography are previously exposed on their borders to a standard light for varying periods of time. When these plates are developed, a scale of tones which allows a comparison of opacities is obtained at the same time as the image of the phenomena.

The spectroscopic examination of the corona confronts us with still more complex and more interesting problems. When we keep the slit of the spectroscope on the crescent of the sun, which narrows more and more in proportion as the moon advances, the spectrum darkens and the dark lines become less and less apparent; then all at once the field of sight is covered with an infinite number of bright lines, which seem to be substituted for each dark line of the Fraunhofer spectrum. This phenomenon only lasts two or three seconds. Such is the remarkable observation made by Prof. Young in 1870. In the preceding year he had tried to prove this transformation of dark into bright lines, but failed because he had arranged the slit of his spectroscope as a radius to the sun, which gave the bright lines too little length to be perceptible. With a tangential slit, however, the lines were long enough to be easily recognised.

Prof. Young's observations revealed to us the existence round the sun of a layer of incandescent vapours, of relatively low temperature, which, conformably to Kirchoff's theory, produce by their absorbing power reversal of the lines of the solar spectrum. It is very probable that the vapours to which the reversal is due are not all situated in the atmosphere which Prof. Young has revealed to us, and which has a thickness of only 1000 kilometres. If it were so, absorption must be infinitely more intense at the edge of the sun than it is at the centre. Nevertheless, the borders of the sun show no trace of this abnormal absorption. The observations of M. Janssen in 1867 showed this, and it is also proved by photographs of the spectrum of the sun which I took at the annular eclipse of 1890 at Canœ in the island of Crete.

It is probable that the reversal of lines is produced in a series of layers whose total thickness is great enough to make the difference of absorption between the centre and limb of the sun inappreciable. According to Prof. Lockyer the sun should be surrounded by concentric layers of vapours arranged in order of density, which, according to his own expression, envelope the sun like "the leaves of an onion." Prof. Young's layer of vapours would comprehend only some of these layers. This hypothesis seems confirmed by the observation made by M. Trépied in 1882: although he saw "a veritable rain of bright lines in the spectrum," he proved that the coincidence of the bright and dark lines was not complete.

Prof. Lockyer's theory involves also, as another consequence, the unequal length and width of these bright lines; indeed, the layer nearest to the sun should give short lines corresponding to the thickness of this layer, and as the temperature here must be very high the lines should be rather wide. The following layer being seen by projection, and having a thickness equal to the two layers, should give lines twice as long; moreover, this second layer being cooler than the preceding the lines should be narrower. The same reasoning applies to the succeeding layers, so that we ought to find, soon after the beginning of the total eclipse, short and wide lines, then long and narrow ones. The observations of 1882 confirmed these predictions, and English astronomers wished to repeat the experiment in 1886. Unfortunately the observations of Father Perry and Mr. Turner were made under conditions too unfavourable for us to draw any certain conclusion from them. To fully elucidate the question it is necessary to obtain instantaneous photographs of these bright lines. The experiment was indeed attempted by English observers in 1883, but they seem to have obtained no result. Prof. Lockyer proposes during the approaching eclipse to photograph these lines as well as the bright lines of the corona. He intends to use not only an analytic spectroscope, but a prismatic object glass. This apparatus will give the monochromatic images of the corona, that is to say, the kind of rings corresponding to each elementary radiation emitted by the coronal light.

When we turn the spectroscope towards the corona itself we observe a continuous spectrum, crossed by a bright green line which does not belong to any known element. This line, near the line E, corresponds to the division 1474 of Kirchoff's scale, and was at first believed to coincide exactly with a line of iron; but in 1876 Prof. Young was able to separate the line 1474 with powerful dispersion, and proved that one of its two components belongs to iron while the other belongs to the coronal matter. This line 1474 has been shown in every total eclipse, but its intensity has been very variable and seems always to have followed the fluctuations of solar activity. Thus in 1878, a period of maximum spots, the green line was so faintly visible that it escaped all observers except two. On the other hand, in 1882, when the solar activity was almost at its maximum, the green line was visible to within 40′ from the limb. However, we must remember that these estimations made by different observers, observing with very dissimilar instruments, are scarcely comparable, and trustworthy evidence can only be obtained from photographs of the spectrum of the corona. The new plates sensitive to the green will no doubt allow the line 1474 to be photographed in the approaching eclipse.

It would be interesting to know whether the intensity of the green line varies with the brilliancy of the different parts of the corona, whether it is completely wanting in the rifts, whether it extends further than the visible corona, whether it has the same width in its whole extent, &c. These observations can only be made by associating with the spectroscope a telescope serving as a finder, in which cross wires have been arranged to indicate at each moment towards what part of the corona the slit is directed. The spectrum is observed with one eye while with the other the corona is examined. This is the arrangement which M. Janssen has always adopted in his spectrum observations of the corona.

If the terrestrial atmosphere is loaded with water vapour, we must expect a general diffusion of the coronal light, and this is doubtless the reason that on some occasions, as in 1870, the green line is seen beyond the corona—even upon the lunar disc.

Prof. Hastings, in 1883, examined simultaneously with a special arrangement the spectra of east and west portions of the corona, and proved, conformably to the theory that he propounds, that the green line varied in length during the duration of the eclipse, and that it always extended furthest on the most illuminated side of the edge of the moon. Mr. Keeler repeated the experiment in 1889, and also noted that the length of the green line depends upon the position of the sun with respect to the moon. The question would be worth studying further.

The green line is not the only bright line in the spectrum of the corona, the hydrogen lines have also been discovered in it, but these never extend further than about 10′ from the sun's limb. Other bright lines in the red and in the violet were observed by M. Tacchini and by Thallon in 1882. It was in 1882 also that Prof. Schuster obtained the first photograph of the coronal spectrum upon which some thirty bright lines may be counted.

In addition to the incandescent solid or liquid matter producing the spectrum of the corona, and the incandescent gases, which give rise to bright lines, there must also be in the circumsolar regions matter reflecting the light of the photosphere, as our own atmosphere does. This is proved by the polarisation of the light of the corona, and by the presence in its spectrum of the dark lines of the Fraunhofer spectrum. We owe the discovery of these dark lines to M. Janssen. In 1871 he observed only the lines D and *b*, but, since, in 1883, he has recognised some hundred dark lines, thus showing that the complete Fraunhofer spectrum is found in the coronal spectrum. These dark lines are necessarily very faint, for they are drowned in the continuous spectrum. As a rule the line D is most conspicuous, although, according to Prof. Hastings, if a faint solar spectrum is projected on to the continuous spectrum of a gas flame, it is not the line D, but rather the group *b*, which is by far the most apparent. Prof. Hastings concludes from this experiment that the continuous spectrum of the corona is richer in green than in orange radiation, since it causes the group *b* to disappear before the line D.

In conclusion I must quote a remarkable observation made by Prof. Tacchini in 1883, which, should it be confirmed, would suggest a very fascinating theory of the corona. Upon examining the spectrum of one of the sheaves (panaches) of the corona with a considerable dispersion and a wide slit, Prof. Tacchini thought he recognised two or three bright bands characteristic of the hydrocarbons, which are always present in the spectra of comets. Father Perry in 1886 proposed to verify the observation of Tacchini, but unfortunately could not re-observe the bands in question. Certainly he used a spectroscope with slightly illuminated cross wires, and when the period of great solar activity had already passed. It would be well in future eclipses to devote some seconds to the search for these bands, for, if the presence of carbon were recognised in the coronal atmosphere, it would be a new proof of the analogy which exists between the corona and cometary masses. Like comets the corona seems formed of matter subject to a repulsive force on the part of the sun, indeed it is probable that solar gravity does not act upon the corona, for unless this were so, the lower parts, having to support the weight of the upper, would be much more dense than the latter. It would thus result that the lines of the coronal spectrum, the line 1474 for instance, would be wider at their bases than at their upper extremities; but nothing of the kind has hitherto been observed. Moreover, so that the corona may be visible at 30′ or 40′ from the sun, the coronal matter must necessarily not be too rare in these extreme regions; but even in ascribing an extremely low density to this, we should find upon allowing for solar gravity that the pressure near the sun would have a considerable value, although it is proved that the pressure at the base of the corona does not exceed some millimetres of mercury.

It is also sought to prove the slight density of the middle corona by the fact that it has never offered any resistance to comets, which, on several occasions, have passed through it; but as comets themselves experience no appreciable resistance when they encounter a body it is impossible to tell whether the absence of resistance is due to the comets or to the corona.

The repulsive force which expels the coronal matter from the sun would act in the same manner as electrical force; indeed Prof. Bigelow has noticed that the arrangement of plumes and sheaves round the solar disc, and the ircurvilinear forms exactly recall the lines of force of an electric field. Let us complete the parallel between comets and the corona by noting that the tails of comets sometimes assume the curvilinear form found in the sheaves of the corona. The dark parts which divide the tails of comets have also their analogues in the rifts of the corona. To push the comparison still further, it would be very interesting to be able to prove that the corona, like cometary masses, is transparent, and that bright stars can be seen through it. Unfortunately it will be impossible to attempt this experiment at the time of the next eclipse.

An exact photometric study of the solar surface would perhaps detect the transparency of the corona, indeed if we suppose that the corona presents a certain opacity the parts of the photosphere on which the large sheaves are projected must be less luminous than the parts covered by the polar rays.

If the corona is not subject to solar gravity it is scarcely probable that it shares the movement of rotation of the sun; however, it would be useful to try in the coming eclipse to study the question by the spectroscopic method, as M. Trouvelot wished to do in 1883. It would be desirable to conduct all spectroscopic observations of the corona by means of photography. The instruments which must be used for this purpose should be very luminous (*i.e.* give bright images), for there is little light available, and the exposures are necessarily short. In studying the effectiveness of a spectroscope in the case of an object presenting a large apparent diameter, like the corona, it is seen that the intensity of the spectrum depends entirely upon the width of the slit, and the effectiveness of the object glass which forms the image of the spectrum. As to the collimator and the condenser their dimensions are of no importance, provided that the collimator can well receive all the light of the condenser. As the object glass which forms the image of the spectrum must have an image long enough to give sufficient length to the spectrum, one is led, in order to obtain great effectiveness, to give this object glass a large aperture, and consequently to use a prism of large size.

The visibility of the bright lines depending not only on their brightness, but also on their width, a wide slit must be employed to obtain a good image of these lines; on the other hand, a narrow slit will give a spectrum of great purity, and will show the dark lines. The employment of two different spectroscopes is then plainly indicated.

It remains for us to speak of the photometric measuring of the corona by optical photometers. Bunsen's photometer has already been used for this purpose, but I think that we must henceforth turn to photography to obtain exact results. The question should not be neglected, for it is certain that the brilliancy of the corona varies considerably from one eclipse to another. Thus Prof. Lockyer estimates that in 1878, at a period of quiescence on the surface of the sun, the corona was ten times less brilliant that in 1871.

Let us end by pointing to the polariscope observations which hitherto have been far from giving concordant results as to the proportion of polarised light in the various parts of the corona. Here also there are new inquiries to be made.

Such, gentlemen, are the different problems suggested by the study of the solar corona. We will hope that the next eclipse will largely contribute to their solution.

MEMORIAL OF SIR RICHARD OWEN.

A MEETING was held at the rooms of the Royal Society, on Saturday, to make preparations for the provision of a suitable memorial of the late Sir Richard Owen. The Prince of Wales took the chair, and was supported by the Duke of Teck, the President, the Treasurer, and the Secretary of the Royal Society, Lord Kelvin, Sir John Evans, and Professor Michael Foster; the President of the British Association, Sir A. Geikie; the President of the Royal College of Physicians, Sir A. Clark; the President of the Royal College of Surgeons, Mr. T. Bryant; the President of the Royal Academy, Sir F. Leighton; the Bishop of Rochester, the Dean of Westminster, Lord Playfair, Prof. Huxley, Sir H. Roscoe, M.P., Sir F. Abel, Sir F. Bramwell, Sir G. Stokes, Sir H. Acland, Sir Joseph Lister, Mr. Ericsen, Dr. Priestley, Dr. Günther, Dr. H. Woodward, Dr. Maunde Thompson, Sir W. H. Flower, Sir Erasmus Ommanney, Sir James Paget, Sir Henry Thompson, Sir Spencer Wells, Sir Edwin Saunders, Sir John Fowler, Dr. E. A. Bond, Dr. P. L. Sclater, Mr. Carruthers, and Mr. W. P. Sladen. There were also present, among others, Sir G. M. Humphry, Mr. Holman Hunt, Mr. Ernest Hart, Dr. Michael (President of the Royal Microscopical Society), Prof. R. Meldola, Mr. O. Salvin, and Prof. T. Wiltshire.

The Prince of Wales, in opening the proceedings, said,—I have the great privilege conferred upon me of being asked to take the chair to-day, upon this very special occasion. We are assembled together for the purpose of paying a mark and tribute of respect and appreciation to the memory of a great man of science who has lately passed away from us. The name of Sir Richard Owen must always go down to posterity as that of a great man—one who was eminent in the sciences of anatomy, zoology, and palæontology. Perhaps I may be allowed to say a word of my own personal knowledge of him. It is now thirty-five years since I had the advantage of knowing him. When I lived as a boy at the White Lodge, Richmond Park, now occupied by my illustrious relative on my right (the Duke of Teck), I had opportunities of visiting him and knowing him. His geniality and his charm of manner to all those who knew him have, I am sure, left a deep and lasting impression. Whether he was explaining to you the mysteries of some old fossil bone that had been given him, or whether he was telling one of his vivid ghost stories, one felt that one was under the charm of his presence. His method of teaching, as you all know, was earnest and clear in every respect; and it even derived a measure of force from a certain hesitation in his manner. His great repute was gained as a zoologist, and in the study, not only of living animals, but of those long extinct, and following the same large range of work as Cuvier, to whom, in the history of science, he may be regarded as a successor. One of the great works and interests of his life was the formation of the Natural History Museum, which is now safely established in South Kensington under the able guidance of our friend Sir William Flower. It may be within your recollection what great difficulties Sir Richard Owen encountered when he was first appointed Superintendent of the Department of Natural History at the British Museum in 1856. He himself saw in getting that appointment that it was quite impossible that these large collections could be adequately seen unless they were removed to some other sphere. In 1862 a Bill was brought in by Mr. Gladstone, who took the greatest interest in the matter, while it was vigorously opposed, strange to say, by no less great a man than Mr. Disraeli. The Bill was lost, though it was eventually, ten years later, carried, and now we have that fine building that we all know and deeply appreciate. I may also mention that he took the greatest interest with regard to the colonies, and in trying to obtain from them specimens that would be worthily represented in the Natural History Museum. In sanitary matters also he was not behindhand, as was shown by his long intimacy with that distinguished man, Sir Edwin Chadwick. There are several resolutions to be proposed, and you will hear far better and more eloquent remarks from the distinguished gentlemen who will move and second them. That is the reason why on this occasion I shall not trouble you with more remarks. Allow me only to repeat the assurance of the deep interest I take in this movement for a suitable memorial to the memory of this great man, and how deeply I appreciate having been asked to take the chair on this interesting and important occasion.

Lord Kelvin moved:—"That it is desirable that the eminent services of the late Sir Richard Owen in the advancement of the knowledge of the sciences of anatomy, zoology, and palæontology should be commemorated by some suitable memorial." He said that, if there was no other reason but the part that Sir R. Owen took in the establishment of the Natural History Museum, and the success that ultimately attended his efforts, he deserved the gratitude of the nation. There was scarcely any branch of the whole of natural history that he had not touched and enriched with the results of his investigations. Three hundred and sixty papers, every one of them valuable, were to be found under his name in the Royal Society catalogue of scientific papers. From these contributions, however, he came back to the Natural History Museum, and he held that every subject of the Queen, in these islands or in the colonies, and every visitor to this country, must feel that he was benefited by the existence of that museum and by the splendid arrangement of its contents.

Prof. Huxley, in seconding the resolution, said that, if he mistook not, there were very few men living who had had occasion to follow the work of the remarkable man whose career they had met to celebrate with more carefulness and attention than he had done. It was a career remarkable for its length, for the rapid rise to eminence, and the long retention of high position of the person who was the subject of it. It was more than forty years ago since he, as a young man, had occasion to look abroad upon the scientific world of London, in which he was then a complete novice, and to see whether, perhaps, in some small and insignificant corner of it room might be found for him. At that time there were four persons whose names stood out amongst the first in the galaxy of scientific men of this country. They were Sir John Herschel, Mr. Faraday, Sir Charles Lyell, and, last, though by no means least, the famous Hunterian Professor, Owen. If he looked abroad amongst the lights of biological science, with which he was principally concerned, there were Johannes Müller in Berlin, Milne Edwards in Paris, Von Baer in St. Petersburg; but for quantity, general excellence, and variety of work there was no one who could be regarded as the superior of Owen. It was a common impression that Owen was the successor and continuator of Cuvier, and that was largely true. The memoirs on the pearly nautilus, on the marsupials, on the anthropoid apes were fully worthy of the author of the "Memoires sur les Mollusques" or the "Leçons d'Anatomie Comparée," while the "Ossemen fossies" had a full equivalent in the vast series of papers upon fossil remains, contained in the publications of the Royal, the Geological, and the Palæontographical Societies. But it was also to be remembered that, in another field, Owen was the successor and continuator of the school to which Cuvier was most vehemently opposed—that of St. Hilaire and Oken. The remarkable contributions to morphology embodied in the works on the archetype of the vertebrate skeleton and on the nature of limbs were able developments of speculative views of another order than Cuvier's. Readers of Goethe would remember that he thought the news of the controversy between Cuvier and St. Hilaire far more interesting than that of the Revolution of July, which broke out about the same time. Whether that was a just estimate of the relative importance of things or not might be left an open question; but it was the peculiar irony of history to show us in so many quarrels that right and wrong were on both sides. And in this particular controversy it had turned out that the right lay neither with Cuvier nor with St. Hilaire, but partly with both and partly with a third party, which at that time hardly existed. Whatever might be the ultimate verdict of science in this particular matter, there could be no doubt that it was a distinct aid to progress to have one view of the case stated and illustrated with the unrivalled wealth of knowledge which Owen brought to bear upon it. If history confirmed, as he believed it would, the estimate of the broad features of Sir Richard Owen's work, which he had suggested, then it would justify them in endeavouring to preserve the memory of the great results achieved by his stupendous powers of work, his remarkable sagacity in interpretation, and his untiring striving towards the ideal which he entertained.

The resolution was then put and agreed to unanimously, as were also those which followed.

The Duke of Teck moved:—"That the memorial shall consist primarily of a marble statue which shall be offered to the Trustees of the British Museum to be placed in the hall of the Natural History Museum." His Royal Highness said,—There is no doubt, in my mind at least, that this would be the most appropriate place and the most appropriate form in which to erect the likeness of our admired friend. It is, so to say, his second home, the home of his later labours, and no better place could be found. Besides, I think it is a very nice idea that every one who enters the hall should see first of all the man to whom we owe this inheritance. Others have said so much about Sir Richard Owen that it is needless for me to go over the ground again. As all of us know so well, what he has been and what he has done will remain in the minds of all who survive him, and, therefore, I will only say that in my opinion the hall, which is a very fine interior, of the Natural History Museum should be the place where the memorial of this great man should be erected.

Sir William Flower, in seconding the resolution, said that having twice in his life succeeded Sir Richard Owen, he had had special opportunities of judging of his work, and he might, therefore, be expected to say something about the general character and extent of that work on the present occasion, but after what had been said in the introductory remarks of His Royal Highness, and the speech of Prof. Huxley, than whom no one was more competent to give an opinion upon the scientific side of the question, there was no necessity for doing so. He could not refrain, however, from speaking upon one point. Among the various characteristics of Sir Richard Owen, one of the most remarkable was his untiring industry, which enabled him to produce an amount of work which was truly prodigious. It could hardly be expected that such a vast series of memoirs on so many diverse subjects, as that which he had given forth to the world during his long life, could all be equal in quality, or that the merits of some of them should not have been the occasion of controversy. He would only refer to one instance of this kind. As long ago as 1837, Sir R. Owen read a paper before the Society in whose rooms they were now assembled, which was published in the Philosophical Transactions, and in which certain remarkable characteristics were stated to exist in the brain of marsupial animals, widely distinguishing them from other members of the class to which they belong. The conclusions apparently established by this paper were generally accepted for nearly thirty years, but in 1865 another memoir was read before the same society, and also published in the Philosophical Transactions, in which a different view was taken both of the nature of the structural peculiarities and of their significance in classification. The views of the author of this second paper have generally found favour until within a few months since, when an independent investigation of the subject, carried on with all the improved methods of modern research, by Dr. J. Symington, has resulted in a declaration in favour of the accuracy of Owen's original description and conclusions. These observations may still require confirmation by others, but as he (Sir W. Flower) was the author of the second paper, he considered it only fitting that he should, at a meeting assembled to do honour to the memory of the great anatomist, from whom, on this point, he had differed so long, call attention to them. He thought this the best contribution he could make to the object for which they had gathered together.

Dr. P. L. Sclater suggested that, in addition, a memorial catalogue of the late professor's writings should be issued, with a portrait and biographical memoir.

Sir James Paget moved that a committee be formed to carry out the preceding resolutions. It would be impossible, he said, to have any better evidence that the resolutions just passed were right than the number and position of those who had offered to serve on the committee, for there was never a more representative list. Headed by the Prince of Wales, the Duke of Teck, the Archbishop of Canterbury, and the Lord Chancellor, it contained nearly 150 of the most prominent workers in all branches of science and many who were the best judges of the influence of science on the general well-being of the nation. He was the oldest person present who had worked with Sir R. Owen, and could remember him on entering St. Bartholomew's Hospital as a student in 1834. He could testify to the influence Owen had exercised in promoting the study of science by showing to all around him how keen his delight was in it, and how in itself alone it might be a sufficient reward. He resisted all temptations to leave science, though he might have been a very successful medical practitioner; and he was one of the first by whom the real reform of sanitary matters was begun in this country.

Sir J. Evans briefly seconded the motion.

Sir A. Clark moved—"That the following list of gentlemen constitute the executive committee: His Royal Highness the Prince of Wales (chairman), His Serene Highness the Duke of Teck, the President of the Royal Society, the President of the Royal College of Physicians, the President of the Royal College of Surgeons, the President of the Linnæan Society, the President of the Zoological Society (treasurer), Sir John Evans, Prof. Michael Foster, Dr. A. Günther, Prof. Huxley, Sir F. Leighton, Sir James Paget, Dr. P. L. Sclater, Mr. W. Percy Sladen (secretary), Lord Walsingham, Mr. A. Waterhouse, R.A., and Mr. Henry Woodward." Sir Andrew remarked that this memorial movement reminded them that nations no more than individuals can live by bread alone. Material prosperity did not constitute the true abiding life of a nation; it was necessary that it should live by ideas: and the nation honoured those who, like Owen, communicated new ideas which spurred others to new courses of activity.

Mr. T. Bryant, in seconding the motion, said the College of Surgeons felt the loss that science had sustained in the death of him who unquestionably was the grand expounder of John Hunter and who, more than any one else, demonstrated the value of the materials John Hunter left behind him. He did more than any one else to call the attention of the scientific world to the museum in Lincoln's Inn, and by additions to it to make it what it is. More than that, at a time when comparative anatomy and biological studies were little thought of he called attention to the value of them, the necessity for them, and the pleasures they would yield. As a young man he attended Owen's lectures, and felt the full force of his quiet enthusiasm, which was altogether independent of the materials embodied in the lectures.

Lord Playfair, in supporting the motion, said that he was the last surviving member of the Health of Towns Commission of 1844, upon which he was brought into continual intercourse with Sir R. Owen, and therefore he knew how much Sir Richard had at heart the advancement of sanitary science. This interest in it he maintained throughout his whole career. He lived close to Sir Edwin Chadwick, and although no two men could be more unlike, they were most intimate friends, and were constantly discussing how to advance the health of the nation. When Sir Richard returned from his interesting expedition to Egypt he told the speaker that he had come back in an unforgiving spirit towards Moses, because though skilled in the learning of the Egyptians, and having derived his chief commandments from those of that ancient race, he missed one important one, "Thou shalt not pollute rivers." Owen, like Prof. Huxley, exercised great influence outside the domain of science. Prof. Huxley had benefited the education of the country, and Prof. Owen had considerable influence in improving the sanitary condition of the country.

Sir W. Flower read a first list of donations, headed with one of £25 by the Prince of Wales.

Sir Henry Acland moved, and Prof. Michael Foster seconded, a vote of thanks to his Royal Highness for consenting to become chairman of the committee, and for presiding on the present occasion.

The Prince of Wales, in responding, said,—I beg to return my warmest thanks to my kind and valued old friend, Sir Henry Acland, for the way he has proposed, to Mr. Michael Foster for the way in which he seconded, and to you all for the kind manner in which you have received this resolution. It has indeed been a labour of love to me to-day to preside on this very interesting occasion, and I think that it has seldom been my good fortune to listen to more interesting or eloquent addresses than those which have fallen from the lips of those eminent gentlemen who have spoken. Nobody will take a deeper interest in the carrying out of this memorial of our lamented friend Sir Richard Owen than myself, and most sincerely do I hope that the great work that is to adorn the Natural History Museum will be worthy of a great sculptor and of the great man that it represents.

SCIENTIFIC SERIALS.

Bulletin de l'Académie Royale de Belgique, Nos. 9 and 10. Classe des Sciences.—On some new *Caligidei* of the coast of Africa and the Azores Archipelago, by P. J. van Beneden.—On an optical atmospheric phenomenon observed in the Alps, by F. Folie (see Notes).—On a state of matter characterised by the mutual independence of the pressure and the specific volume, by P. de Heen. It is easily shown that the density of saturated vapour at the critical temperature is variable, and depends, at constant pressure, upon the proportion of liquid enclosed in the tube. Experiments were made in order to decide whether this independence of pressure and volume was shown also at other temperatures. The liquid chosen was ether, and the volume of liquid and vapour contained in a sealed tube was read by means of a cathetometer. A series of results showed that during condensation by pressure the density of unsaturated vapour was greater than that of saturated vapour, or that the specific volume increased with the pressure. This is an experimental verification of Prof. James Thomson's pseudo gaseous state of matter.—On the most complete reduction of invariant functions, by Jacques Deruyts.—Ex-meridian observations made at the Royal Observatory of Belgium from March to October, 1892, by L. Niesten and E. Stuyvaert.—On a new fluorine-derivative of carbon, by Frédéric Swarts. This is a liquid, of the formula CCl_5F, boiling at 24°·7, insoluble in water, and unaffected by sulphuric and nitric acids. Its density is 1·4944; an alcoholic solution of potash destroys it gradually, forming potassium chloride, fluoride, and carbonate. It was obtained by treating carbon tetrachloride with a mixture of antimony trifluoride and bromine in equal molecular proportions. It is notable that the bromofluoride produced by the mixture acts not as a bromising but a fluorising agent.—On a simplification of some of Tesla's experiments, by H. Schoentjes. Like some recent workers in England, Prof. Schoentjes has found that most of the experiments can be produced, although with lesser intensity, without the bobbin immersed in oil, the discharge exciter, and the condenser, simply by the first Rhumkorff coil, whose dimensions need not exceed 7 × 17 cm.—On a process of sterilisation of albumin solutions at 100° C., by Émile Marchal. Albumin can be easily sterilised at 100° C., without coagulation, by first adding 0·05 gr. per litre of borax, or 0·005 of ferrous sulphate in a 2 to 5 per cent. solution, or 4 to 5 gr. nitrate of urea per litre of 10 per cent. solution. The "incoagulable albumin" thus obtained is perfectly suitable for cultivations.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 24, 1892.—"Memoir on the Theory of the Compositions of Numbers," by P. A. MacMahon, Major R.A., F.R.S.

In the theory of the partitions of numbers the order of occurrence of the parts is immaterial. Compositions of numbers are merely partitions in which the order of the parts is essential. In the nomenclature I have followed H. J. S. Smith and J. W. L. Glaisher. What are called "unipartite" numbers are such as may be taken to enumerate undistinguished objects. "Multipartite" numbers enumerate objects which are distinguished from one another to any given extent; and the objects are appropriately enumerated by an ordered assemblage of integers, each integer being a unipartite number which specifies the number of objects of a particular kind; and such assemblage constitutes a multipartite number. The 1st Section treats of the compositions of unipartite numbers both analytically and graphically. The subject is of great simplicity, and is only given as a suitable introduction to the more difficult theory, connected with multipartite numbers, which is developed in the succeeding sections.

The investigation arose in an interesting manner. In the theory of the partitions of integers, certain partitions came under view which may be defined as possessing the property of involving a partition of every lower integer in a unique manner. These have been termed "perfect partitions," and it was curious that their enumeration proved to be identical with that of certain expressions which were obviously "compositions" of multipartite numbers.

The generating function which enumerates the composition has the equivalent forms—

$$\frac{h_1 + h_2 + h_3 + \dots}{1 - h_1 - h_2 - h_3 - \dots},$$

$$\frac{a_1 - a_2 + a_3 - \dots}{1 - 2(a_1 - a_2 - a_3 - \dots)},$$

where h_s, a_s represent respectively the sum of the homogeneous products of order s and the sum of the products s together of quantities

$$\alpha_1, \alpha_2, \alpha_3, \dots, \alpha_n,$$

and the number of compositions of the multipartite

$$\overline{p_1 p_2 \dots p_n}$$

is the coefficient of $\alpha_1^{p_1}\alpha_2^{p_2} \dots \alpha_n p^n$ in the development according to ascending powers.

It is established that

$$\tfrac{1}{2}\frac{1}{\{1 - s_1(2\alpha_1 + \alpha_2 + \dots + \alpha_n)\}\{1 - s_2(2\alpha_1 + 2\alpha_2 + \dots + \alpha_n)\} \dots \{1 - s_n(2\alpha_1 + 2\alpha_2 + \dots + 2\alpha_n)\}}$$

is also a generating function which enumerates the compositions; the coefficient of

$$s_1^{p_1}s_2^{p_2} \dots s_n^{p_n}\alpha_1^{p_1}\alpha_2^{p_2} \dots \alpha_n^{p_n}.$$

being the number of compositions possessed by the multipartite

$$\overline{p_1 p_n \dots p_n}.$$

The previous generating function may, by the addition of the fraction $\frac{1}{2}$ and the substitution of $s_1\alpha_1$, $s_2\alpha_2$, &c., for α_1, α_2, &c., be thrown into the form

$$\tfrac{1}{2}\frac{1}{1 - 2(\Sigma s_1\alpha_1 - \Sigma s_1 s_2\alpha_1\alpha_2 + \dots (-)^{n+1}s_1 s_2 \dots s_n\alpha_1\alpha_2 \dots \alpha_n)},$$

and hence these two fractions, in regard to the terms in their expansions which are products of powers of $s_1\alpha_1, s_2\alpha_2, \dots, s_n\alpha_n$, must be identical. This fact is proved by means of the identity—

$$\tfrac{1}{2}\frac{1}{\{1 - s_1(2\alpha_1 + \alpha_2 + \dots + \alpha_n)\}\{1 - s_2(2\alpha_1 + 2\alpha_2 + \dots + \alpha^n)\} \dots \{1 - s_n(2\alpha_1 + 2\alpha_2 + \dots + 2\alpha_n)\}}$$

$$= \tfrac{1}{2}\frac{1}{1 - 2(\Sigma s_1\alpha_1 - \Sigma s_1 s_2\alpha_1\alpha_2 + \dots (-)^{n+1}s_1 s_2 \dots s_n\alpha_1\alpha_2 \dots \alpha_n)}$$

multiplied by

$$1 + \Sigma\frac{2(A_{\kappa_1} + \alpha_{\kappa_1}) \dots (A_{\kappa t} + \alpha_{\kappa t}) - (A_{\kappa_1} + 2\alpha_{\kappa_1}) \dots (A_{\kappa t} + 2\alpha_{\kappa t})}{(1 - S_{\kappa_1}) \dots\dots\dots\dots (1 - S_{\kappa t})} s_{\kappa_1}s_{\kappa_2} \dots s_{\kappa n},$$

where

$$S_\kappa = s_\kappa(2\alpha_1 + \dots + 2\alpha_\kappa + \alpha_{\kappa+1} + \dots + \alpha_n) = s_\kappa(A_\kappa + 2\alpha_\kappa),$$

and the summation is in regard to every selection of t integers from the series

$$1, 2, 3, \dots n,$$

and t takes all values from 1 to $n - 1$.

This remarkable theorem leads to a crowd of results which are interesting in the theory of numbers.

The geometrical method of "trees" finds a place, and, lastly, there is the fundamental algebraic identity—

$$\frac{1}{k}\frac{1}{\{1 - s_1(k\alpha_1 + \alpha_2 + \dots + \alpha_n)\}\{1 - s_2(k\alpha_1 + k\alpha_2 + \dots \alpha_n)\} \dots \{1 - s_n(k\alpha_1 + k\alpha_2 + \dots + k\alpha_n)\}}$$

$$= \frac{1}{k}\frac{1}{1 - k\Sigma s_1\alpha_1 + k(k-1)\Sigma s_1 s_2\alpha_1\alpha_2 - \dots + (-)^n k(k-1)^{n-1}s_1 s_2 \dots s_n\alpha_1\alpha_2 \dots \alpha_n}$$

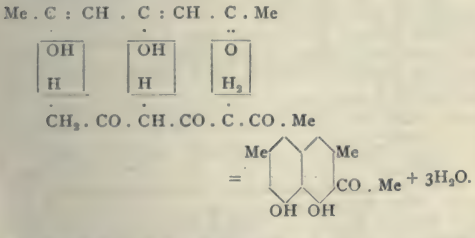
multiplied by

$$1 + \Sigma\frac{k(A_{t_1} + \alpha_{t_1}) \dots (A_{t_n} + \alpha_{t_n}) - (A_{t_1} + k\alpha_{t_1}) \dots (A_{t_n} + k\alpha_{t_n})}{(k-1)(1 - S_{t_1})(1 - S_{t_2}) \dots (1 - S_{t_n})} s_{t_1}s_{t_2} \dots s_{t_n},$$

which reduces to that formerly obtained when k is given the special value 2.

Chemical Society, December 13.—Mr. W. Crookes, Vice-President, in the chair.—The Stas Memorial Lecture, by J. W. Mallet, was read (see this vol. p. 248).

December 15.—Dr. W. J. Russell, Vice-President, in the chair.—The following papers were read:—The identity of caffeine and theine and the interactions of caffeine and auric chloride, by W. R. Dunstan and W. F. J. Shepheard. Various physiologists have concluded that differences exist between theine from tea and caffeine from coffee; the authors have compared the products from the two sources, and consider that their identity is beyond question. The differences in physiological action observed by Mays, Brunton, and Cash can only mean that the alkaloids employed were either impure or administered under non-comparable conditions. On heating an aqueous solution of caffeine aurichloride, a yellow precipitate of aurochlorocaffeine $C_8H_9(AuCl_2)N_4O_2$ separates; the production of this substance is better explained by Medicus' formula for caffeine than by that of E. Fischer.—Studies on isomeric change, ii. Orthoxylenesulphonic acids, by G. T. Moody. 1:2:3-orthoxylenesulphonic acid, when heated at 115–120° in a current of dry air, undergoes quantitative conversion into the isomeric 1:2:4-sulphonic acid. The former acid is prepared by sulphonating dibromorthoxylene and reducing the resulting dibromorthoxylenesulphonic acid with zinc dust and sodium hydroxide. A number of derivatives are described.—Studies on isomeric change, iii. Phenetoilsulphonic acids, $C_6H_4(OEt)SO_3H$, by G. T. Moody. Bromophenetoilsulphonic acid, prepared by ethylating parabromophenol and sulphonating the bromophenetoil so obtained, is readily reduced by zinc dust and sodium hydroxide with formation of orthophenetoilsulphonic acid. The latter is completely converted into the isomeric parasulphonic acid on heating for several hours at 100°. Lagai's observations, contradicting the author's previous results, are shown to be erroneous.—Formation and nitration of phenyldiazoimide, by W. A. Tilden and J. H. Millar. Phenyldiazoimide, $N_3.Ph$, is readily obtained by the interaction of nitrosyl chloride and phenylhydrazine in glacial acetic acid solution; on nitration it yields about two-thirds of its weight of the paranitro-derivative (m.p. 74°). Nitrophenyldiazoimide is a convenient source from which to prepare diazoimide.—The production of naphthalene derivatives from dehydracetic acid, by J. N. Collie. The author concludes that the yellow substance which he has previously obtained by the condensation of diacetylacetone (see this vol. p. 238) is probably formed in accordance with the following equation:—



Me . C : CH . C : CH . C . Me
OH
H
OH
H
O
H₂
CH₂ . CO . CH . CO . C . CO . Me
=
Me
Me
CO . Me
OH OH
+ 3H₂O.

This substance gives a diacetyl derivative which on distillation with zinc dust yields a trimethylnaphthalene. The condensation product closely resembles the acetonaphthols prepared by Wilt and Erdmann.—A new synthesis of hydrindone, by F. S. Kipping. Contrary to the statement of Hughes, hydrindone may be easily prepared in large quantities by the action of aluminium chloride on phenylpropionic chloride; 50–60 per cent. of the theoretical yield is obtained, the reaction being represented by the following equation: $Ph . CH_2 . CH_2 . COCl = Ph\left\langle\begin{matrix}CH_2\\CO\end{matrix}\right\rangle CH_2 + HCl$. The ketone prepared in this way is identical with that obtained from other sources by several chemists; its hydrazone, hydroxime and a nitro-derivative are described. On heating hydrindone with moderately concentrated sulphuric acid a condensation product, $C_{18}H_{14}O$, is obtained; it forms yellowish plates melting at 141·5–142·5°. Phosphoric anhydride converts hydrindone into a yellow crystalline substance, which is apparently identical with the hydrocarbon of the empirical composition C_3H_2, which the author has previously obtained by the action of phosphoric anhydride on phenylpropionic chloride.—The resolution of methoxysuccinic acid into its optically active components, by T. Purdie and W. Marshall. Synthetical methoxysuccinic acid can be resolved into its optically active constituents by crystallisation of the acid cinchonine salts, the salt of the dextro-acid being less soluble in water than that of its lævo-isomeride. The separation effected in this way is, however, only partial, the metallic salts obtained after removal of the alkaloid being a mixture of the active and inactive compounds; by taking advantage of the fact that the inactive calcium or acid potassium salt is less soluble in water than its active isomeride, the optically active acids may be isolated. The active acids have a specific rotatory power of about 33° in 5–10 per cent. aqueous solutions and melt at 88–90°, whilst the inactive acid melts at 108°. The rotation of the normal ammonium or potassium salt is of the same sign as that of the parent acid; the rotation of the calcium or barium salt is of opposite sign to that of the acid, but varies greatly with change of concentration. The rotation of the barium salt changes sign in very dilute solutions.—Optically active ethoxysuccinic acid, by T. Purdie and I. W. Walker. If fed with nutritive mineral salts the spores of *Penicillium glaucum* flourish in a solution of inactive hydrogen ammonium ethoxysuccinate and consume the lævogyrate acid, leaving the dextro-acid unaltered. On crystallising the cinchonidine salt of the inactive acid, a separation into the lævo- and dextro-modifications may be effected, and the oppositely active acid ammonium salts prepared in this way resemble that obtained by means of *Penicillium glaucum*. Close parallelism exists between the methoxy- and ethoxy-succinates, with respect to optical activity.—The formation of benzyldihydroxypyridine from benzylglutaconic acid, by S. Ruhemann. Ethyl benzylglutaconate slowly dissolves at 100° in concentrated aqueous ammonia, yielding a solution, from which acids separate benzyldihydroxypyridine. This substance exhibits both basic and acid properties and melts at 184°.—The action of nitrous acid on 1-α-amido-2-β-naphthol; a correction, by R. Meldola. The author agrees with the statement of Grandmougin and Michel that β-naphthaquinone results from the interaction of nitrous acid and 1-α-amido-2-β-naphthol.—Note on the action of phenylhydrazine on mono- and di-carboxylic acids at elevated temperatures, by W. R. Hodgkinson and A. H. Coote. On distilling a mixture of phenylhydrazine and phenylacetic acid in equivalent proportion, benzene, aniline and a liquid of the composition $C_{14}H_{12}O_2$ distil over; nitrogen and ammonia are also evolved. As has been previously shown, the hydrazide of the composition $Ph . CH_2 . CO . NH . NH . Ph$ is the first product of the reaction; on distilling this substance, $NH . NH$ is split off, and reduces the phenylhydrazine present to aniline and benzene. Somewhat similar reactions occur in the cases of orthotoluic, phenylpropionic, and succinic acids, and are now under investigation.

SYDNEY.

Royal Society of New South Wales, September 7, 1892.—Prof. Warren, President, in the chair.—Paper read: The effect which settlement in Australia has produced upon the indigenous vegetation, by A. G. Hamilton [Part I.].

October 5.—Prof. Warren, President, in the chair.—The second part of paper on the effect which settlement in Australia has produced upon indigenous vegetation, by A. G. Hamilton, was read, after which the society's bronze medal and a cheque for £25 were presented to the author.

November 2.—Prof. Warren, President, in the chair.—Dr. William Huggins, F.R.S., was elected an honorary member of the Society. The following papers were read:—Preliminary note on limestone occurring near Sydney, by H. G. Smith.—On a cyclonic storm near Narrabri, by H. C. Russell, F.R.S.—Some folk-songs and myths from Samoa, translated by the Rev. G. Pratt, with introduction and notes by Dr. John Fraser.

PARIS.

Academy of Sciences, January 16.—M. de Lacaze-Duthiers in the chair.—Swimming movements of the ray-fish, by M. Marey. These were investigated by means of chronophotography, ten exposures being made per second. The fish was fixed in position by the head and tail, and the views were taken from the front and the side respectively, the fins being left free to move. The photographs show the successive phases of one entire motion of the fins, which consists of a wave-like motion beginning in front. Shortly after the anterior portion has been lifted it is depressed, the motion being meanwhile propagated to the lateral portions, and growing in amplitude as the fin grows in breadth. Just before the movement dies out near the tail the process recommences in front. The periodic time was 0·8 seconds. The photographs show a striking likeness to those obtained by chronophotography applied to the flight of birds. M. Marey intends to study the mechanical effect of the action of the fins upon the water, also by the aid of photography.—Microscopic researches on the contractility of the blood-vessels, by M. L. Ranvier. The pericœsophagian membrane of the frog was placed on the disc of the slide-cell in one or two drops of peritoneal serum. It was kept extended by a platinum ring; electrodes of tinfoil were placed in connection, and a cover glass was fixed over the whole with paraffin. Thus mounted, the smooth muscular fibres and the internal elastic sheath are well seen. On connecting the induction coil with the electrodes, the muscular fibres contract as soon as the current is strong enough. At the same time, the folds of the internal sheath become more pronounced and finally touch, thus effacing the passage through the small artery. On breaking the current, the artery gradually regains its original diameter. If the current is not sufficiently strong for producing a regular contraction, some of the segments contract, while others are at rest. But the zone of contraction is never displaced, and, if interrupted, will reappear at the same place on reestablishing the current. Nothing corresponding to a peristaltic motion can be produced by direct electrical excitement. In none of the experiments, even with the strongest currents, was it possible to detect any signs of contraction in the capillaries.—On the sum of the logarithms of the first numbers not exceeding x, by M. Cahen.—On differential equations of a higher order, the integral of which only admits of a finite number of determinations, by M. Paul Painlevé.—On linear differential equations with rational coefficients, by M. Helge von Koch.—Electric waves in wires; depression of the wave propagated in conductors, by M. Birkeland (see *Wiedemann's Annalen*, abstract).—On the minimum perceptible amount of light, by M. Charles Henry. This was estimated by Aubert at $\frac{1}{300}$th of the light of the full moon. This is about a thousand times too great, as proved by some measurements made with the zinc-sulphide (phosphorescence) photometer previously described. The corrected formula for the rate of loss of luminosity of the sulphide is $i^{0·5}(t - 18·5) = 1777·8$, which agrees even with the longest observations, and is theoretically justified by M. Henri Becquerel. The minimum perceptible amount of light was determined by noticing the time at which the eye, previously kept in the dark for one hour, could only just distinguish the light emitted by the phosphorescent substance, taking care to test for illusions by the successive interposition of ground-glass screens. The time thus found was four hours, giving an amount of light of 29×10^{-9} standard candles at 1 m. If the eye is previously kept in the dark during varying periods, the minimum varies inversely as the square of the time during which it is kept dark.—On phosphorescent sulphide of zinc, considered as a photometric standard, by the same. Careful tests showed that the light emitted by zinc sulphide at a given instant is independent of the distance of the illuminating magnesium ribbon, of the time of illumination, and of the thickness of the layer, and is also uniform in samples prepared under different conditions, thus exhibiting all the requisites of a secondary photometric standard.—On an acid plato-nitrite of potassium, by M. M. Vèzes.—Decomposition of chloroform in presence of iodine, by M. A. Besson.—On some ethers of homopyrocatechine, by M. H Cousin.—On the determination of phosphorus in iron and steel, by M. Adolphe Carnot. The new method, based like most others on the employment of ammonium molybdate, differs from them in the mode of separation of the silicon, which is effected by sulphuric acid; in the process of destruction of the carbon compounds, brought about by chromic acid; and in the nature of the final compound, which is not magnesium pyrophosphate, but dry phosphomolybdate of ammonia, which only contains 1·628 per cent. of phosphorus, thus ensuring a greater accuracy in the quantitative estimation.—Losses of nitrogen in manure, by MM. A. Muntz and A. Ch. Girard.—Researches on the localisation of the fatty oils in the germination of seeds, by M. Eugène Mesnard. It appears that, except in the grasses, the fatty oil is not specially localised. It is in all cases independent of the starch and the glucose, but it appears superposed upon the albuminoid materials in the reserves of ripe seeds.

BERLIN.

Physical Society, December 16, 1892.—Prof. Kundt, President, in the chair.—Dr. Lummer spoke on the principles involved in the use of half-shade polarimeters. He showed that the difference in brightness of the two halves of the field of the instrument depends first on the angle between the two polarising prisms, the less this is the greater being the difference produced by a minimal rotation of the analyzer, and secondly on the power of perceiving minute differences of brightness. In connection with the latter he had made some changes in the Lippich instrument which presented some distinct advantages.—Prof. Goldstein gave an account of some experiments made many years ago, but not yet published. He first dealt with the light which appears at the anode, and which, as compared with that of the kathode, has as yet been but little investigated. As is well known, a kathode consisting of two metals emits rays of different brightness from its two parts, thus for instance the aluminium emits brighter rays than does the silver. When this electrode is used as an anode, the reverse holds good, inasmuch as the anodic light of silver is brighter than that of aluminium. The difference is, however, only observed in rarefied oxygen, and does not exist in a hydrogen tube, and is hence due to oxidation of the silver. The second set of experiments dealt with Crookes' supposed reciprocatory deflection of kathodic rays of similar direction. The speaker had shown, by shielding one of the electrodes, that the deflection is apparent, not real. The change in the path of the kathodic radiation is due entirely to the effect of the second electrode upon the rays emitted by the first.

TROPICAL AGRICULTURE.

A Text-book of Tropical Agriculture. By H. A. Alford Nicholls, M.D., F.L.S., C.M.Z.S., with illustrations, pp. 312. (London: Macmillan and Co., 1892.)

THIS text-book is the English edition of a work that has already received high commendation from the Government of Jamaica. The Government of this now prosperous colony, in pursuance of a policy (which may well be followed by other colonies) offered a premium of one hundred pounds for the best text-book of Tropical Agriculture adapted for the use of colleges and higher schools in the colony. The award was made to Dr. Nicholls's manuscript, and after the publication of the work in Jamaica it was adopted also as a text-book by the Government of other colonies, so that its value has been practically estimated beforehand. The author's qualifications for the task he has undertaken may be gathered from the following:—

> "Twelve years ago, when he had to direct his attention to tropical agriculture, there was no practical book that he could turn to for help in all the difficulties that were constantly cropping up in his path. Knowing, therefore, the obstacles that usually beset the inexperienced planter who is not content to follow the old grooves of unscientific agriculture, the author has so written the second part of this book as to afford the information he needed greatly in his own planting novitiate. This has rendered it necessary to enter into details, which to the experienced agriculturist may appear superfluous, but the book is really intended as a guide to the young and unlearned to whom such details are likely to be of essential service."

As an introduction to tropical agriculture this book supplies a want long felt. There are several works of a technical character treating of old and well-established industries such as sugar, tea, coffee, cacao. None of these, however, could be adopted as text-books in schools. Indeed they all presuppose such a close acquaintance with the principles and terminology of tropical agriculture that they appeal to a very limited class of readers. Hitherto, tropical agriculture, to a large extent, has borrowed most of its methods from the agriculture of temperate climates and adapt them, as well as it could, to the very different circumstances of the torrid zone. The result has been by no means satisfactory. In tropical regions effects follow cause so rapidly that methods admirably adapted to the cold, sluggish climates of northern countries are most injurious when too closely followed in the tropics. As instances we may cite the serious effects on climate following the extensive cutting down of forests, and the wholesale washing away of surface soil from land under permanent cultivation by the destructive influences of tropical rains. The merit of Dr. Nicholls's book lies in the fact that its precepts are directly based on his own experience, and he appeals so effectively to the intelligence of his readers that they cannot fail to be instructed. The work is divided into two parts:—Part I. deals with the elementary principles of agricultural science and discusses amongst other subjects the origin and composition of soils, the nature of plant life, the controlling influence of climate, the action and constituents of manures, the rotation of crops, the drainage of soils, irrigation, tillage operations, pruning, budding, and grafting. In Part II. there is treated the application of these principles to some of the chief of the various cultivations undertaken in tropical countries. As examples we may mention that there are detailed accounts given of the methods found most successful in the cultivation of coffee, cacao, tea, sugar-cane, fruits, spices, tobacco, drugs, dyes, tropical cereals, and such food plants as cassava, arrowroot, yams, sweet potato, tania (*Colocasia*).

The book is intended also, according to the preface, to be of service to peasant proprietors, owners of small estates, and to those [European] settlers who from time to time may wish to make their homes in the tropics. It is just these people who are now building up the new prosperity of the West Indies by means of what are called "minor industries" or *la petite culture*—which the French have found so remunerative in many of their colonies. To guide and instruct the mass of small cultivators in the West Indies has been the dream of the most enlightened Governors, such as Sir John Peter Grant, Sir Anthony Musgrave, Sir William Robinson, and others that have ruled there for the last thirty years. The intelligent settlers of European origin can very well take care of themselves: but the mass of the small cultivators are black people. They have, it is true, received some education, and they are not wanting in intelligence in regard to what concerns their own interests, but their methods of cultivation have, hitherto, been of the rudest and most destructive description. They crop the land year after year without any manuring, and when it is thoroughly exhausted they move on, when they can, to fresh land, and treat that in exactly the same way. Thus in the black man's system of cultivation the rotation is of land, and not of crops, and the future has to take care of itself. This is a relic of the times of slavery, when the negroes were allowed as much land as they cared for—out of reach of sugar cultivation—to grow provisions for their own subsistence. It is now necessary to change the whole character of the black man's cultural methods, or the rich and fertile lands still left in the West Indies will be absolutely ruined. Generally only the lowest class of negroes have hitherto been attracted to field work. The education given to these people is responsible for something of this result, for it leads them, in too many cases, to regard labour in the field as degrading, and almost a return to a state of slavery. The sharper and more intelligent boys, when they leave school, are drawn away to seek a precarious existence as clerks in stores or as small shopkeepers, where they seldom do more than copy the weaknesses and vices of the whites, while, according to our author, if they took to the land, and had a right understanding of agricultural methods, they "need never despair of becoming prosperous." In the more advanced colonies, such as Jamaica, there is a disposition to establish industrial schools and train the younger generation in approved methods of cultivation, and lead them to regard the tillage of the soil as a more honourable and remunerative occupation than petty trading. We may hope that the claims of industrial education will become more widely recognized, not only in the West Indies but in all our tropical colonies where native races have to be dealt with. In the meantime colleges and schools must prepare competent instructors for the work, and for both teacher and taught this book is an admirable starting-point. In it the whole field of small industries is well covered, and the language is clearly expressed and well chosen. As an example of the author's treatment we find under manures (p. 49):—

"The land must be regarded by the planter as a bank in which he has opened an account. If he continually draw cheques on the bank, and make no fresh deposit to meet the drain, he will sooner or later come to the end of his capital, and the same argument applies to the soil. In cacao and coffee cultivation in the West Indies, particularly on lands of peasant proprietors, one often sees the planter take away crops year after year, whilst he does next to nothing to make up for the heavy drain on the land; and then, after a time he finds he gets very small crops, and he thinks the fault lies with the trees, or that the soil is not adapted to the cultivation, whereas the fault is entirely his own, as he has gone on taking away from the soil without putting anything back." Again, "the great fault hitherto committed by tropical planters has been the confining of their attention to one kind of cultivation on their land. If several different crops were taken off alternately, as in a system of rotation, or grown in different parts of the land, where the soil and climate prove suitable, the planter would be in a much better position than he is now, for he would not 'have all his eggs in one basket.'"

It is noticed that the valuable services rendered to colonial industries by Kew and by the various botanical institutions in correspondence with Kew are fully recognised. Further, the dedication of this first Text-book of Tropical Agriculture to Sir Joseph Hooker is a compliment not only to his own distinguished services, but also to those of his father, for both in their day took the deepest interest in the West Indies. It must be gratifying to the late Director of Kew to learn "in the quiet of his retirement that the influence of his work lives on and bears fruit even in the far-away field" of the West Indies.

D. M.

CELLS: THEIR STRUCTURE AND FUNCTIONS.

Die Zelle und Die Gewebe, Grundzüge der allgemeinen Anatomie und Physiologie. Von Prof. Dr. Oscar Hertwig. (Jena: Gustav Fischer, 1892.)

TEXT-BOOKS on Histology introduce the structure of the tissues to their readers by a chapter on cells, and the best treatises on Anatomy, either human or comparative, usually devote some pages to the consideration of these, the most elementary of all the tissues. As so many important advances have been made of late years in our knowledge of the structure of cells and their contained nuclei, of the properties of protoplasm, of the division of nuclei and the part played by the nucleus in cell multiplication, and of the influence exercised by cells in the problems of hereditary transmission, the time has obviously arrived for the production of a treatise devoted to the description of the cell in its various aspects, observational as well as speculative. No better expositor of the subject in all its bearings could be found than Prof. Oscar Hertwig, who has himself conducted important investigations on this branch of anatomy. The book now before us treats of the general anatomy and physiology of cells, and is to be followed by a second volume, in which the origin and physiological properties of the tissues are to be expounded, as well as their structure.

After a sketch of the history of the cell theory and of the theory of protoplasm, in which, as is too often the case in German text-books, the names of British observers and authors are conspicuous by their absence, he defines a cell to be a little clump of protoplasm which incloses a specially-formed constituent, the nucleus; a definition which accords with those previously made by Leydig and Max Schultze. He then describes at considerable length the characters of protoplasm, both anatomical and physiological, and the chemico-physical and morphological properties of the nucleus. In a short section he discusses the question, Do elementary organisms exist without nuclei? *i.e.* Can you have little clumps of non-nucleated protoplasm pursuing an independent life? As is well known, Haeckel described organisms of this simple character, as cytodes, and gave Monera as an example; but Hertwig is disposed to think that such non-nucleated organisms have not been definitely demonstrated in the animal kingdom, and he quotes Bütschli's observations, which seem to show that even in such micro-organisms as Bacteria a differentiation of a nucleus from surrounding protoplasm can be distinguished.

Two important chapters are written on the movements of protoplasm, of cilia, of flagella, of spermatozoa, on contractile vesicles, and on the irritability of protoplasm under the stimulus of heat, light, electricity and several kinds of mechanical and chemical irritants. The fifth chapter is devoted to the consideration of the nutritive changes and formative activity in cells. Illustrations are given of the power possessed by certain unicellular organisms of taking into their substance and digesting solid bodies of various kinds, and an account is appended of the important observations of Metschnikoff on phagocytosis.

Chapters six and seven are occupied with a description of the multiplication of cells, their mode of division, and the method of fertilization. The process of karyokinesis is described at some length and in its various phases, in clear and precise language, and with an amount of illustration which enables the reader to follow without difficulty this complicated process. The influence exercised by the nucleus, and the part which it plays in the process of cell multiplication, has now been put by the labours of many investigators on a basis of observation, both as regards plants and animals, such as cannot be controverted, and the accuracy of the generalization made half a century ago, both by Martin Barry and John Goodsir, that young cells originate through division of the nucleus of a parent cell, has been amply established.

Dr. Hertwig also recites observations which seem to show that the nucleus does more than act as a reproductive centre within the cell, but also takes a part in cell nutrition. This function of the nucleus was also contended for by Goodsir, but during the period when protoplasm was regarded as the essential element in nutrition or secretion, the claim of the nucleus to take any share in this phase of cell activity was summarily put aside. Recent observations have, however, shown that clumps of protoplasm, removed from either a unicellular plant or animal, in which no nucleus is present, although capable of living, and retaining their irritability and power of movement for some time, yet neither grow, nor form a cell membrane, nor have the same power of digesting bodies introduced into their substance, as is possessed by a clump of protoplasm which has retained the nucleus. The nutritive activity of the protoplasm would appear, therefore, to be under the influence of the nucleus.

The volume concludes with a chapter on the cell in its relation to theories of heredity. The author, as is now the prevailing opinion amongst biologists, contends that the nucleus is the conveyer of hereditary properties, and that the offspring is a mixed product of both its parents, derived from the ovum and the sperm cell. In the course of this chapter he discusses the views of Darwin, Spencer, Nägeli, Weismann, and De Vries, and suggests the employment of the term "Idioblasts" for the minute elementary particles, which Darwin called "gemmules" in his hypothesis of pangenesis, and which he conceived to be capable of transmitting hereditary characters to succeeding generations.

THEORETICAL MECHANICS.

Elementary Mechanics of Solids and Fluids. By A. L. Selby, M.A. (Oxford: Clarendon Press, 1893.)

AT a period when we are bound to recognize the influence exerted by the examinations of the various educational institutions and of those controlled by other more or less influential examining bodies, we may be excused, on the arrival of a new work, for stating whether or not, and to what extent, it is adapted to their requirements. The book before us does not appear to have been intentionally written for examination purposes, and perhaps on this account it will be all the more welcome. Its purpose, however, is very distinct. It is intended for those students who are desirous of reading mechanics as an introduction to a study of physics. So far, therefore, as its suitability for examinations is concerned, we can heartily recommend it to those who wish to qualify in this particular branch of science, while at the same time it will be read with great benefit by that class of students who desire a thorough knowledge of the portions generally included under the head of Theoretical Mechanics.

In the study of such subjects as the book treats of, the amount of knowledge which the reader may have of mathematics will, to a considerable extent, be a measure of his success. The author expresses a hope that an acquaintance with the elements of algebra and geometry will suffice; but, while not wishing to reduce the usefulness of the book, but rather to direct it into proper hands in which it will be read with greater advantage, we think it would be nearer the mark to say that a thorough knowledge of elementary algebra and a considerable acquaintance with elementary trigonometry are necessary. Certainly the definitions of the trigonometrical ratios will be found in an appendix, but it will be far better if the student has lived with and used these for some time.

Possessing these requirements, he will appreciate and even admire the broad, yet concise nature of the treatment generally; and with regard to this matter we may say that we are unacquainted with any elementary text-book better calculated to create a desire for precise and full ideas. That this is requisite for a study of physics perhaps more than any other subject, no one will deny.

The first chapter of the book is occupied with a consideration of Kinematics, and in it will be found a careful exposition of the displacement, velocity, and acceleration to which a body may be subjected, due attention being drawn to what is necessary for a full representation of them. The appendix following this contains some geometrical theorems and definitions for subsequent use. Then follow the usual chapters on the laws of motion, work, and energy, centre of gravity, moments of inertia, and simple machines. A chapter on gravitation will be read with interest, preceded as it is by an explanation of some of the geometrical properties of the ellipse. Kepler's laws of planetary motion are dealt with, in addition to other relevant matters which do not usually find their way into elementary text-books.

The subject of elasticity also receives a somewhat more extensive treatment than is usually given to it. The various kinds of stress and strain which a body may undergo are explained, together with the relation between stress and strain. At the end of the book we find what is included under the second head of the title. The various principles and laws which refer to fluids, and some of the machines and instruments which depend on them for their action, are enumerated and explained, while the interesting subject of capillarity has a separate chapter devoted to it.

To an appreciative reader it is a source of satisfaction to observe the care the author has exercised when dealing with the important matter of definitions and units—fundamental and derived. A chapter on units and their dimensions is furnished at the end.

A good selection of examples, bearing on the matter treated therein, will be found at the close of the chapters.

Many portions of the book are characterized by a decided freshness of treatment, and we have little doubt that the careful reader will find many little points which are satisfying, in that they tend to widen the somewhat restricted views he may have previously held, and these will be all the more apparent should his mind be of a mathematical turn.

G. A. B.

OUR BOOK SHELF.

Magnetism and Electricity. By R. W. Stewart. (London: W. B. Clive and Co.)

THE book forms one of the University Correspondence College Tutorial Series, and is "primarily written for the use of candidates for the Matriculation, Intermediate Science, and Preliminary Scientific Examinations of the University of London." The author is evidently familiar with the difficulties which usually occur to students, and the best portions of the book are those in which efforts are made to elucidate some of the more general errors. The descriptions of apparatus and phenomena are, however, generally rather short and meagre, while the diagrams are frequently inadequate for a work of this sort. Little is written to help the beginner to perform experiments for himself; in fact, descriptions of many important instruments are omitted—for example, the Wheatstone

Bridge—and to students having no access to a laboratory little satisfaction will be given when told: "The details of the construction and practical use of the different forms of Wheatstone's Bridge used in the measurement of resistance are best learnt in the laboratory, and for this reason we shall not give any further description of the arrangement."

In many instances the student is driven through a mass of theory before he has a fair idea of the general phenomena; thus in the introductory chapter on "Current Electricity," after a six-line description of a simple cell and current, over two pages are occupied in proving that the effects produced could be explained by the dissociation and procession of the hydrogen and oxygen atoms. The work is generally remarkably free from errors and misprints, but one occurs in the explanation just mentioned. The attraction of zinc for oxygen is said to be much greater than that of the copper, while later the zinc is also considered "to *repel* hydrogen *less*." Here, and in many other instances, the words to be emphasised are printed in italics. Another mistake will be found on pp. 168 and 169, where in comparing, by the method of oscillations, the field due to a magnet with that of the earth, the author starts with the equation $\frac{I+H}{I}=\frac{n_1^2}{n^2}$ instead of $\frac{I+H}{H}=\frac{n_1^2}{n^2}$, and reasoning correctly from this false hypothesis, he deduces false results, while the answer to Ex. 8 on this part of the subject appears incorrect. Fig. 13, p. 201, in illustration of Oerstedt's experiment, is not correctly drawn.

The arrangement of "calculations" and examples at the end of each chapter must prove extremely useful to students possessing beforehand an elementary knowledge of the general phenomena, and to such, rather than to the very beginner, the book may be commended. H. S. J.

Manners and Monuments of Prehistoric Peoples. By the Marquis de Nadaillac. Translated by Nancy Bell (N. D'Anvers). (New York and London: G. P. Putnam's Sons, 1892.)

A BOOK summing up in a popular style all that is now known with regard to prehistoric man would probably be welcomed by a tolerably large class of readers. The present work does not quite supply the kind of summary that is wanted. The author does not distinguish with sufficient clearness between the various periods with which he deals; he indulges too freely in talk of a vaguely moralising tendency; and some of his statements do not accord with the conclusions of the best authorities. Speaking of the Round Towers of Ireland, for instance, he says, "According to the point of view of different archæologists, they have been called temples of the sun, hermitages, phallic monuments, or signal towers." The reader is thus left to suppose that the question is still open, whereas all competent students of the subject accept the theory of the late Mr. Petrie, a theory which the Marquis de Nadaillac does not even mention. However, the author has presented a large number of interesting facts in the course of his exposition, and there are occasional passages in which he brings out very well the attractive elements of some of the more fascinating departments of archæology.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Two Statements.

IN a letter addressed to the *Daily Chronicle*, dated January 25, 1893, Prof. Karl Pearson makes two statements respecting my opinions and grounds of action:

"As in society at large, so in academic matters, his mode of insuring progress is unlimited individual competition,"

and again:

"he is an individualist in all matters."

Seeing that in an essay "On Administrative Nihilism," published twenty-two years ago; and in another on "Government: Anarchy or Regimentation," published in 1890, I have done my best to combat the doctrine Prof. Pearson attributes to me, I shall be glad to know what justification he has to offer for so grave a misrepresentation. The purpose of it is obvious.

T. H. HUXLEY.

Hodeslea, Eastbourne, January 29.

A Meteor.

THE following is taken from the Pretoria *Weekly Press* for January 7: "A few evenings ago a meteor of unusual size and brilliancy was observed at Bloemfontein shooting right across the eastern sky. It looked like a rocket of a greenish colour, and burst in a shower of sparks in the south-east. The spectacle was much admired by those who were fortunate enough to witness it."

This meteor, as seen in South Africa, appears to have had many points in common with a similar one seen in England about the same time, and reported by several observers in the daily Press.

W. L. DISTANT.

Purley, Surrey, January 31.

"Hare-lip" in Earthworms.

ATTENTION has recently been drawn by Prof. Andrews (*American Naturalist*, September, 1892) and myself (*Science Gossip*, 1892) to some abnormal conditions of life among the terrestrial annelids. I have now to place on record a totally new appearance, which is, I think, very aptly expressed by the term "hare-lip." The worm which I have had under examination presented the peculiarity figured below, and when alive and in motion suggested to my mind most forcibly the appearance which we associate with the name I have adopted.

The specimen in question belongs to the genus Allolobophora, in which genus, so far as my experience goes, almost all the abnormalities are found. The genus Lumbricus, it should be observed, is very seldom, if ever, known to present any of these peculiarities. Hitherto the Long worm (*A. longa*, Ude) has been most prolific of bifurcated heads and tails. Now we find the Green worm (*A. chlorotica*, Savigny) yielding new features for study. The peculiarities which have presented themselves in former times have usually taken the form of a second head or a supernumerary tail. In this instance there is no off-growth, however, but merely a malformation of the anterior segments. One might have supposed that the peculiarity was due to accidental causes. It would have been easy to suppose that the head had been split, and then the wound had healed, leaving a seam down the middle. I observed, however, that each of the three specimens of the Green worm which I received from Cork (Ireland) showed some abnormal feature, and there were other peculiarities in this particular specimen which indicated that we had to deal with a congenital rather than an accidental condition of things.

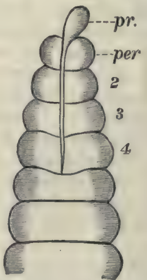

Diagram of the anterior portion of green-worm (*Allolobophora chlorotica*, Savigny), showing abnormal appearance of lip (*pr*), peristomium (*per*), and three succeeding segments, seen from above, and enlarged.

As this is the first occasion on which such a peculiarity has been recorded or figured, I prefer to leave all speculation as to the cause out of the question. We need a good deal more research before we can deal satisfactorily with the biological problems involved in such appearances. As a help towards this, I bring together here a list of all those works which have come under my own and Prof. Andrews's notice, in which abnormalities in annelids are recorded :—

HILDERIC FRIEND.

The Zero Point of Dr. Joule's Thermometer.

IN the course of a discussion on "Exact Thermometry" I described (NATURE, vol. xli. p. 488) the results obtained by heating thermometers for a considerable time to 280° and 356°; and pointed out by means of a diagram that at 356°, after about ten hours, the rise of the zero point became—at any rate approximately—a rectilinear function of the logarithm of the time; though at 280°, even after more than 300 hours' heating, the rise appeared to be rather more rapid than would correspond to such a simple relation.

Dr. Joule observed the rise of the zero point of a thermometer at the ordinary temperature during a course of no less than thirty-eight years ("Scientific Papers," vol. i. p. 558), and it occurred to me that it would be of interest to ascertain the relation to the logarithm of the time in this case also.

The following table contains the dates of Dr. Joule's observations; the total number of months from the date when the first reading was taken; the corresponding logarithms; the total rise of the zero point in scale divisions (13 divisions to 1° F.); the total rise calculated from the formula $R = 6{\cdot}5 \log. t - 4{\cdot}12$, where t is the time in months; and lastly the differences between the observed and calculated zero points.

Date.	Time in Months.	Log. t.	Total rise of zero point in scale divisions. Observed.	Calculated.	Δ

The agreement between the observed and calculated values is certainly remarkable, and the + and − differences are evenly distributed.

Ten years have now elapsed since the last reading was taken, and if the thermometer is still in existence it would be of great interest to know what further rise has taken place in its zero point. According to the equation the reading should now be 13·86.

SYDNEY YOUNG

University College, Bristol, January 20.

THE APPROACHING SOLAR ECLIPSE, APRIL 15-16, 1893.

THE total solar eclipse of April 15–16, 1893, is not only one of the longest of the century, but is the last of the century from which we are likely to get any addition to our knowledge of Solar Physics. The longest duration of totality of this eclipse is 4 minutes 46 seconds, and as the path of the moon's shadow lies to a great extent on land, there is a considerable choice of possible stations with long durations of totality. Commencing in the Southern Pacific the line of totality passes in a north-easterly direction and enters Chili at Charañah in 29° southern latitude, crosses the South American continent, and issues at Para Cura, a village near Ceara, at the north-east corner of Brazil, in latitude 3° 40′ south. It crosses the Atlantic at its narrowest part and enters Africa at Point Palmerin, near Joal, almost midway between Bathurst and Dakar, and in latitude 14° north; the shadow finally leaving the earth in the interior of Northern Africa. The eclipse will be observed by several parties of astronomers in Chili, Brazil, and Africa, there being almost absolute certainty of fine weather in Chili and Africa, and a reasonable probability in Brazil.

The English arrangements to observe the eclipse have been made by a joint committee of the Royal Society, the Royal Astronomical Society, and the Solar Physics Committee of the Science and Art Department, South Kensington; Dr. A. A. Common, LL.D., F.R.S., undertaking the duties of Secretary. Two expeditions will be sent from England, one to Africa and the other to Brazil, the expenses being defrayed by a grant of £600 from the Royal Society.

The African expedition will be in charge of Prof. T. E. Thorpe, and will consist of Prof. Thorpe, Mr. A. Fowler, Mr. Gray, and Sergeant J. Kearney, R.E. The Brazilian expedition will be in charge of Mr. A. Taylor, who will have with him Mr. W. Shackleton.

Prof. Thorpe and his party will leave Liverpool by the British and African mail steamer on March 18th, arriving at Bathurst on April 2nd. They will be met at Bathurst by a gunboat kindly placed at the disposal of the expedition by the Admiralty, and will be conveyed at once to Fundium, a station on the Salum River, about sixty miles from Bathurst; this being the station selected by the Committee from the three which were offered by the French Government. The gunboat will remain with the expedition, and the officers and crew will assist in the preparations for and in the actual observations of the eclipse. After the eclipse the party will be taken to Bathurst on the gunboat, and will return to England by a British and African mail steamer, if one is available. From the time-tables of the steamers now published it appears, however, that there will not be any mail steamer available until the end of April, and in this case a cruiser will meet the party at Bathurst and bring them to the Canary Islands or to Gibraltar, from either of which places they will be able to return by mail steamer, arriving in England early in May.

The members of the expedition to Brazil will leave Southampton by the Royal Mail steamer on February 23 for Pernambuco, arriving at the latter place on March 12. They will take passage by the local mail steamers to Ceara, at which place they will arrive about March 20.

The Brazilian Government are willing to place a war vessel at the disposal of the foreign expeditions to observe the eclipse, and it is hoped the English observers will be able to avail themselves of the privilege thus gracefully offered. The station selected is at Para Cura, on the coast about forty miles west of Ceara, and the party will rely upon obtaining any necessary help from the Brazilian authorities and from local assistants. The observers will return from Pernambuco by the Royal Mail steamer due to leave there on April 22, and expect to be in England on May 5.

The objects of the expeditions are—

(1) To obtain visual photometric measures of the light of the corona.

(2) To obtain photographs of the corona with the four-inch lenses of a little over sixty inches focus belonging to Captain Abney, which were successfully used in Egypt (1882), Caroline Island (1883), Granada (1886), and Salut Isles (1889), in order to continue the series.

(3) To obtain enlarged photographs of the corona with small photographic action, so as to show details of the structure of the brightest parts, *i.e.* those nearest the sun.

(4) To measure the photographic intensity of the light of the corona, by direct comparison with standard intensity scales placed on the margins of the plates used for the negatives to be obtained under sections 2 and 3.

(5) To obtain photographs of the spectrum of the corona. These spectra will be obtained on three different plans:—

(*a*) With integrating spectroscopes, where no collimator is used and the prism or prisms are placed directly in front of the object glass of the photographic camera.

(*b*) With ordinary slit spectroscopes, the slit being arranged as a radius of the sun.

(*c*) With ordinary slit spectroscopes, the slit being arranged as a tangent to the sun's limb.

The first of these objects will be attempted only at the African station; Prof. Thorpe and his assistant, Mr. Gray, making the observations. Their equipment will consist of a six-inch Simms equatorial of seventy-eight inches focus (lent from Greenwich) fitted with special photometric apparatus lent by Captain Abney. The observations will be made on essentially the same plan as that pursued by Prof. Thorpe at Hog Island, near Granada, in 1886, separate portions of the corona being compared with a standard glow lamp by means of a Bunsen photometer. An integrating box for measuring the total coronal light with as little light from the sky as possible, and an ordinary Bunsen's bar photometer will also be used, these being entrusted to officers of the gunboat.

As regards objects 2, 3, and 4, duplicate apparatus has been arranged for use at the two stations.

A photoheliograph mounting from Greenwich has been lent for Brazil, and an exactly similar instrument from South Kensington for Africa. On each of these mountings a specially designed new double tube will be fixed. An Abney lens will be mounted in one compartment of each of these tubes, and this, with a focal length of sixty inches, will give pictures on the scale of rather more than half an inch to the moon's diameter. In the other compartment a four-inch Dallmeyer photoheliograph lens will be mounted in combination with a specially-constructed two-and-a-half-inch Dallmeyer negative lens of eight inches negative focus; this arrangement giving, with a total length of sixty-eight inches, pictures on the scale of over one-and-a-half inches to the moon's diameter. This latter arrangement is essentially the same as that of Dallmeyer's new telephotographic lens. It will be so arranged that the ratio between the photographic effect of the Abney lens and the new combination will be as 10 : 1.

Special plate holders have been made to fit the double tubes, each of these plate holders carrying two plates, which will be exposed simultaneously to the images formed by the Abney lens and the enlarging combination. The six separate exposures, giving twelve photographs, will be so arranged that the longest exposed pictures with the enlarging combination will have received the same photographic action as the shortest exposed pictures with the Abney lens. The whole of the pictures will thus form a continuous series, all the short exposures in the series having a direct enlargement of three diameters.

In Brazil Mr. Taylor will take charge of this double instrument, and in Africa the similar instrument will be entrusted to Sergeant Kearney. On the night before the eclipse intensity scales for object 4 will be impressed by the use of standard lights and specially-constructed scales kindly supplied by Captain Abney on all the plates to be exposed to the corona. The plates will be developed at the stations as soon as convenient after the eclipse, experience on previous occasions, both by English and American observers, having shown that it is impossible to repack undeveloped plates after exposure in the tropics, and bring them home without serious deterioration.

Similar spectroscopic work is to be carried out at the two stations. For the integrating spectroscope in Africa Mr. Fowler will use a six-inch objective prism with a six-inch photographic lens of about nine-feet focus, mounted on an equatorial stand, belonging to Prof. J. Norman Lockyer, and kindly lent for the expedition. At the Brazilian station Mr. Shackleton will use two three-inch prisms in front of a three-inch photographic lens of about two-feet focus; the spectroscope, which belongs to South Kensington, being arranged horizontally and used with a ten-inch heliostat, also lent by the Science and Art Department. Very short exposures will be given at each station at the commencement and end of totality, so as to obtain, if possible, the very numerous bright lines which have been observed in the chromosphere; and exposures of from 5 to 45 seconds will be given during totality.

In Africa the radial and tangential slit spectroscopes will be mounted together on the Corbett equatorial stand lent from Greenwich, the spectroscopes used belonging to the Royal Society. Mr. Fowler and Sergeant Kearney will erect and adjust these instruments, but the actual exposure, which will extend through the whole of totality, will be made by an officer of the gunboat who will be placed in charge of the instrument. In Brazil the radial and tangential slit spectroscopes will be mounted horizontally and used with a second ten-inch heliostat lent by the Science and Art Department. The erection and adjustment will be made by the observers, but the actual exposure during totality will be entrusted to a local assistant. Orthochromatic plates will be used for all the spectroscopic work, the spectra obtained extending from above D into the ultra-violet.

Briefly summarised, the English programme is as follows:—

In Africa:—Prof. T. E. Thorpe, assisted by Mr. Gray and local assistance—Photometric measures of the visual intensity of the corona with the equatorial photometer, the integrating photometer, and the bar photometer; Mr. Fowler—The six-inch integrating spectroscope; Sergeant Kearney—the Abney and Dallmeyer coronographs; local assistance—the radial and tangential slit spectroscopes.

In Brazil:—Mr. Taylor, the Abney and Dallmeyer coronographs; Mr. Shackleton, the three-inch two-prism integrating spectroscope; local assistance, the radial and tangential slit spectroscopes.

It is not yet decided whether one of the 20-inch mirrors of 45-inches focus specially constructed to photograph the faint extensions of the corona during the eclipse of 1889 (December 21–22) will be taken to Africa. If so it will be entrusted to a local assistant. It was originally intended to use one of these in Africa, and it was hoped that one would be used by the Harvard College

Observatory party, which is to occupy a station in Chili, but Prof. W. H. Pickering writes that difficulties of transport will prevent him from taking the 20-inch mirror he has at Arequipa to the Harvard station; and owing to this and to the already large programme of the English party in Africa there is some doubt whether they will take one of the mirrors. April being the middle of the rainy season in Brazil, it is not deemed advisable to send one of the mirrors to that station.

The duration of totality at Para Cura is four minutes forty-four seconds, the altitude of the sun being between 70° and 80°. At Fundium the totality lasts four minutes eight seconds, the altitude of the sun being about 54°.

The Joint Eclipse Committee having arranged the expeditions and the general scheme of work, final details as to the actual operations have been left to a sub-committee consisting of the Astronomer Royal, Captain Abney, Mr. H. H. Turner, Prof. Thorpe, Mr. A. Taylor, and the secretary, Dr. Common. Prof. Lockyer, previous to leaving England for Egypt, determined the exposures to be given by Messrs. Fowler and Shackleton with the integrating spectroscopes. These, with the final instructions to observers drafted by the sub-committee, will be published in due course.

At present very few details are available as to the actual work to be undertaken by foreign observers. The Harvard College Observatory expedition to Chili has already been mentioned. Prof. Schaeberle, of the Lick Observatory, has already started for Chili, and will use a six-and-a-half-inch equatorial, a five-inch horizontal photoheliograph of forty-feet focus, and a Dallmeyer portrait lens. He will be assisted by Mr. Gale, an amateur, from Paddington, N.S.W. A Chilian party will also observe the eclipse in Chili.

At Para Cura there will probably be two or three American parties, one being announced as probably under Prof. H. S. Pritchett, from Washington University, St. Louis, and another will probably be brought to that station by Prof. David P. Todd. A Brazilian party will also observe. The Bureau des Longitudes, Paris, are sending a complete expedition to Joal, in Africa, under MM. Deslandres and Bigourdan, the latter observer having already started for his station. The work undertaken will be to obtain photographs of the corona and of its spectrum. M. de la Baume Pluvinel will also go to Joal to photograph the corona. At present we have not heard of any Italian expedition, but it is hoped that Prof. Tacchini will be able to arrange to observe the eclipse.

A. Taylor.

MEASURE OF THE IMAGINATION.[1]

THE first perceptible sensation is seldom due to a solitary stimulus. Internal causes of stimulation are in continual activity, whose effects are usually too faint to be perceived by themselves, but they may combine with minute external stimuli, and so produce a sensation which neither of them could have done singly. I desire now to draw attention to another concurring cause which has hitherto been unduly overlooked, or only partially allowed for under the titles of expectation and attention. I mean the Imagination, believing that it should be frankly recognised as a frequent factor in the production of a just perceptible sensation. Let us reflect for a moment on the frequency with which the imagination produces effects that actually overpass the threshold of consciousness, and give rise to what is indistinguishable from, and mistaken for a real sensation. Every one has observed instances of it in his own person and in those of others. Illustrations are almost needless; I may, however, mention one as a reminder; it was current in my boyhood, and the incident probably took place not many yards from where I now stand. Sir Humphrey Davy had recently discovered the metal potassium, and showed specimens of it to the greedy gaze of a philosophical friend as it lay immersed in a dish of alcohol to shield it from the air, explaining its chemical claim to be considered a metal. All the known metals at that time were of such high specific gravity that weight was commonly considered to be a peculiar characteristic of metals; potassium, however, is lighter than water. The philosopher not being aware of this, but convinced as to its metallic nature by the reasoning of Sir Humphrey, fished a piece out of the alcohol, and, weighing it a while between his finger and thumb, said seriously, as in further confirmation, "How heavy it is!"

In childhood the imagination is peculiarly vivid and notoriously leads to mistakes, but the discipline of after life is steadily directed to checking its vagaries and to establishing a clear distinction between fancy and fact. Nevertheless, the force of the imagination may endure with extraordinary power and be cherished by persons of poetic temperament, on which point the experiences of our two latest Poet-Laureats, Wordsworth and Tennyson, is extremely instructive. Wordsworth's famous "Ode to Immortality" contains three lines which long puzzled his readers. They occur after his grand description of the glorious imagery of childhood, and the "perpetual benediction" of its memories, when he suddenly breaks off into—

"Not for these I raise
The song of thanks and praise,
But for those obstinate questionings
Of sense and outward things,
Fallings, from us, vanishings," &c.

Why, it was asked, should any sane person be "obstinately" disposed to question the testimony of his senses, and be peculiarly thankful that he had the power to do so? What was meant by the "fallings off and vanishings," for which he raises his "song of thanks and praise"? The explanation is now to be found in a note by Wordsworth himself, prefixed to the ode in Knight's edition. Wordsworth there writes—"I was often unable to think of external things as having external existence, and I communed with all I saw as something not apart from, but inherent in, my own immaterial nature. Many times while going to school have I grasped at a wall or tree to recal myself from this abyss of idealism to the reality. At that time I was afraid of such processes. In later times I have deplored, as we all have reason to do, a subjugation of an opposite character, and have rejoiced over the remembrances, as is expressed in the lines 'Obstinate questionings,' &c." He then gives those I have just quoted.

It is a remarkable coincidence that a closely similar idea is found in the verses of the successor of Wordsworth, namely, the great poet whose recent loss is mourned by all English-speaking nations, and that a closely similar explanation exists with respect to them. For in Lord Tennyson's "Holy Grail" the aged Sir Percivale, then a monk, recounts to a brother monk the following words of King Arthur:—

"Let visions of the night or of the day
Come, as they will; and many a time they come
Until this earth he walks on seems not earth,
This light that strikes his eyeball is not light,
The air that smites his forehead is not air,
But vision," &c.

Sir Percivale concludes just as Wordsworth's admirers formerly had done: "I knew not all he meant."

Now, in the *Nineteenth Century* of the present month

---

[1] Extract from a lecture on "The Just-Perceptible Difference," delivered before the Royal Institution, on Friday, January 27, by Francis Galton, F.R.S. We hope to give next week an extract on "Optical Continuity."

[1] Knight's edition of Wordsworth, vol. iv. p. 47.

Mr. Knowles, in his article entitled "Aspects of Tennyson," mentions a conversational incident curiously parallel to Wordsworth's own remarks about himself:—"He [Tennyson] said to me one day, 'Sometimes as I sit alone in this great room I get carried away, out of sense and body, and rapt into mere existence, till the accidental touch or movement of one of my own fingers is like a great shock and blow, and brings the body back with a terrible start."

Considering how often the imagination is sufficiently intense to stimulate a real sensation, a vastly greater number of cases must exist in which it excites the physiological centres in too feeble a degree for their response to reach to the level of consciousness. So that if the imagination has been anyhow set into motion, it shall as a rule originate what may be termed *incomplete* sensations, and whenever one of these concurs with a real sensation of the same kind, it would swell its volume.

This supposition admits of being submitted to experiment by comparing the amount of stimulus required to produce a just perceptible sensation, under the two conditions of the imagination being either excited or passive.

Several conditions have to be observed in designing suitable experiments. The imagined sensation and the real sensation must be of the same quality; an expected scream and an actual groan could not reinforce one another. Again, the place where the image is localised in the theatre of the imagination must be the same as it is in the real sensation. This condition requires to be more carefully attended to in respect to the visual imagination than to that of the other senses, because the theatre of the visual imagination is described by most persons, though not by all, as internal, whereas the theatre of actual vision is external. The important part played by points of reference in visual illusions is to be explained by the aid they afford in compelling the imaginary figures to externalise themselves, superimposing them on fragments of a reality. The visualisation and the actual vision fuse together in some parts, and supplement each other elsewhere.

The theatre of audition is by no means so purely external as that of sight. Certain persuasive tones of voice sink deeply, as it were, into the mind, and even simulate our own original sentiments. The power of localising external sounds, which is almost absent in those who are deaf with one ear, is very imperfect generally, otherwise the illusions of the ventriloquist would be impossible. There was an account in the newspapers a few weeks ago of an Austrian lady of rank who purchased a parrot at a high price, as being able to repeat the Paternoster in seven different languages. She took the bird home, but it was mute. At last it was discovered that the apparent performances of the parrot had been due to the ventriloquism of the dealer. An analogous trick upon the sight could not be performed by a conjuror. Thus he could never make his audience believe that the floor of the room was the ceiling.

As regards the other senses the theatre of the imagination coincides fairly well with that of the sensations. It is so with taste and smell, also with touch, in so far that an imagined impression or pain is always located in some particular part of the body, then if it be localised in the same place as a real pain, it must coalesce with it.

Finally, it is of high importance to success in experiments on Imagination that the object and its associated imagery should be so habitually connected that a critical attitude of the mind shall not easily separate them. Suppose an apparatus arranged to associate the waxing and waning of a light with the rising and falling of a sound, holding means in reserve for privately modifying the illumination at the will of the experimenter, in order that the waxing and waning may be lessened, abolished, or even reversed. It is quite possible that a person who had no idea of the purport of the experiment might be deceived, and be led by his imagination to declare that the light still waxed and waned in unison with the sound after its ups and downs had been reduced to zero. But if the subject of the experiment suspected its object he would be thrown into a critical mood; his mind would stiffen itself, as it were, and he will be difficult to deceive.

Having made these preliminary remarks, I will mention one only of some experiments I have made and am making from time to time, to measure the force of my own imagination. It happens that although most persons train themselves from childhood upwards to distinguish imagination from fact, there is at least one instance in which we do the exact reverse, namely, in respect to the auditory presentation of the words that are perused by the eye. It would be otherwise impossible to realise the sonorous flow of the passages, whether in prose or poetry, that are read only with the eyes. We all of us value and cultivate this form of auditory imagination, and it commonly grows into a well-developed faculty. I infer that when we are listening to the words of a reader while our eyes are simultaneously perusing a copy of the book from which he is reading, that the effects of the auditory imagination concur with the actual sound, and produce a stronger impression than the latter alone would be able to make.

I have very frequently experimented on myself with success, with the view of analysing this concurrent impression into its constituents, being aided thereto by two helpful conditions, the one is a degree of deafness which prevents me when sitting on a seat in the middle rows from following memoirs that are read in tones suitable to the audience at large; and the other is the accident of belonging to societies in which unrevised copies of the memoirs, that are about to be read, and usually in monotones, are obtainable, in order to be perused simultaneously by the eye. Now it sometimes happens that portions of these papers, however valuable they may be in themselves, do not interest me, in which case it has been a never-flagging source of diversion to compare my capabilities of following the reader when I am using my eyes, and when I am not. The result depends somewhat on the quality of the voice; if it is a familiar tone I can imagine what is coming much more accurately than otherwise. It depends much on the phraseology, familiar words being vividly re-presented. Something also depends on the mood at the time, for imagination is powerfully affected by all forms of emotion. The result is that I frequently find myself in a position in which I hear every word distinctly so long as they accord with those I am perusing, but whenever a word is changed, although the change is perceived, the new word is not recognised. Then, should I raise my eyes from the copy, nothing whatever of the reading can be understood, the overtones by which words are distinguished being too faint to be heard. As a rule, I estimate that I have to approach the reader by about a quarter of the previous distance, before I can distinguish his words by the ear alone. Accepting this rough estimate for the purposes of present calculation, it follows that the potency of my hearing alone is to that of my hearing *plus* imagination, as the loudness of the same overtones heard at 3 and at 4 units of distance respectively; that is as about 3^2 to 4^2, or as 9 to 16. Consequently the potency of my auditory imagination is to that of a just perceptible sound as 16–9, or as 7 units, to 16. So the effect of the imagination in this case reaches nearly half-way to the level of consciousness. If it were a little more than twice as strong it would be able by itself to produce an effect indistinguishable from a real sound.

Two copies of the same newspaper afford easily accessible materials for making this experiment, a few words having been altered here and there in the copy to be read from.

I will conclude this portion of my remarks by suggesting that some of my audience should repeat these experiments on themselves. If they do so, I should be grateful if they would communicate to me their results.

PROTOCERAS, THE NEW ARTIODACTYLE.

Last year the American Museum of Natural History established a department of mammalian palæontology for the purpose of securing and exhibiting collections from all the tertiary horizons of the west. Dr. J. L. Wortman, well known by his discoveries while associated with Prof. Cope, was put at the head of the field work, and under his direction explorations have already been made in the Laramie or Upper Cretaceous, and in three of the great divisions of the tertiary, namely, the Wasatch, the Puerco, and the Lower Miocene or White River.

The discovery of the first example of *Palæonictis* found in America was mentioned in Nature last year. From the Puerco are brought remains of about 400 individuals, adding many new facts to the discoveries of Prof. Cope. From the Laramie are 400 of the small isolated teeth of the kind recently described by Prof. Marsh. These are found by the writer to have a distinctly tertiary rather than mesozoic character, and while intermediate between the mesozoic and Puerco species, they decidedly resemble the latter. *Meniscoëssus*, for example, about which there has been so much discussion, proves to be a plagiaulacid, and also an ancestor of *Polymastodon*, which is thus shown to be a huge *Plagiaulax*, in which the fourth cutting premolar is reduced.

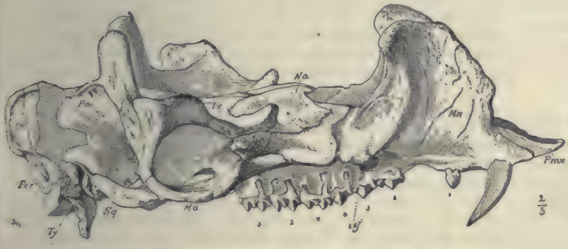

Fig. 1.—Side view of skull.

By far the most perfect specimens have, however, been brought from the Lower Miocene; and here it appears that practically a new horizon has been developed, for the collection is full of fresh forms. Many of these are new species intermediate between the true White River or *Titanotherium* fauna, and the Middle Miocene, but others are new genera, and represent distinct unrelated forms.

In this Lower Miocene collection are included portions of six skulls and the fore and hind feet of an Artiodactyle, of about the size of a sheep. The most complete skull is here figured exactly as found, and is seen at once to depart from all known Artiodactyles in many important characters. There are no less than four protuberances upon each side of the skull. Hindmost are two processes upon the parietals, which are placed upon the superciliary ridges as they diverge from the sagittal crest. These processes are close together and oval in section, reminding us of the posterior pair of horns in *Uintatherium* rather than of the conical or rounded horns found in the giraffes and some other Artiodactyles. Their position upon the parietal bones is also peculiar. The superciliary ridges extend outwards into two widely projecting plates of bone, which curve upwards above the orbits; these plates are upon the frontals, and the frontals also bear a pair of small conical processes just behind their junction with the nasals. But even more exceptional than these parietal and frontal processes are the great vertical plates rising from the maxillaries, slightly recurved, and reaching the full height of the parietal protuberances. Seen from above, these plates are found to be not in contact, but to enclose a long deep cleft, representing the anterior narial opening. This is bridged over posteriorly by the nasals, which, as shown in the second figure, are extremely abbreviated. Correlated with the development of these processes are a number of strong ridges, which form supporting buttresses for the horns. These extend, as above described, from the sagittal crest outwards, also from the anterior margin of the orbit forwards. This lateral maxillary ridge, as it may be called, terminates in a process just above the infraorbital foramen; and this process, although small, seems to illustrate the remarkable tendency of this little skull to develop osseous projections at every available point. The character of these projections is different from that found elsewhere among the Artiodactyla; they are not horn-cores, neither are they similar to the processes upon the parietals of the giraffe. The development of these multiple bony protuberances suggests the skulls of Sivatherium, Tetraceros, and other eastern ruminants; but the proportions of the skull are wholly different. The olfactory chamber, which is usually so expanded in the Artiodactyla, is here extremely reduced; the nasals barely reach beyond the middle line of the skull.

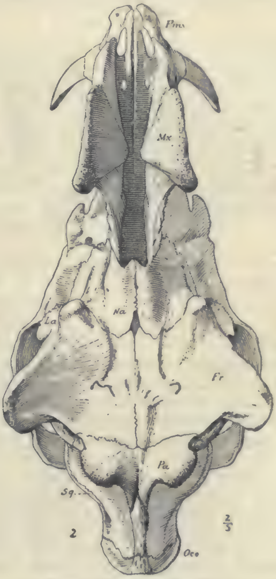

Fig. 2.—Top view of skull.

Up to this point the study of the skull appeared to present an entirely new form, but later the other skulls were removed from the matrix, and among them one was found with small canine teeth, entirely lacking all the processes upon the frontals, and giving indications that those upon the maxillaries were either absent or comparatively small. The parietals were unfortunately missing, but the idea at once suggested itself tha this might be a female skull. Two years ago Prof

Marsh described a small Artiodactyle with a pair of small conical horn-cores upon the parietal bones, which he named *Protoceras celer*, expressing the opinion that it represented a new family. Upon the supposition that this type might also be a female of the same species to which the heavily-horned type belonged, the second skull was taken to the Yale Museum, and carefully compared point by point. It proved to be identical in every respect. In this way the discovery was made that in *Protoceras*, as in so many other Artiodactyles, the male and female skulls differed widely from each other in their cranial armature. The male was as described above; the female exhibits merely a pair of very small conical processes upon the parietals, with perfectly smooth frontals, and maxillaries either of the normal type or with smaller protuberances than in the male.

The dentition at first suggests relationship to *Tragulus* and *Hyomoschus*. The premaxillaries are edentulous as in the ruminants; but in the lower jaw there are four small teeth shaped liked incisors, the outermost of which represents the canine. The upper canines are large, pointed, and recurved. The molar teeth are of the short-crowned, or brachyodont type, with a distinctly crescentic pattern.

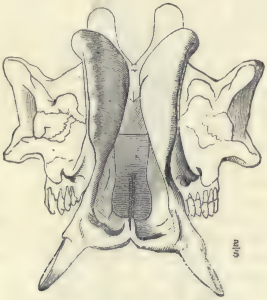

Fig. 3.—Front view of Skull.

The structure of the feet also suggests the Tragulines, in the fact that the fore-foot has four well developed toes, while the hind-foot has two toes with the lateral pair very much reduced. As in the *Tragulidæ*, the fore-foot and probably the fore limb was very much shorter than the hind foot and limb. The hind foot, moreover, shows a tendency to co-ossification both in the metatarsals and in the union of the navicular and cuneiform with the cuboid. In many details, however, the feet present marked differences from the older and more recent Tragulines. The oldest of the Tragulines, moreover, is *Leptomeryx*, a contemporary of *Protoceras*, which has an entirely different skull and foot structure.

Taking all these facts together, we are led to support Prof. Marsh's conjecture, based upon the comparatively hornless female skull, that this Artiodactyle represents a new family, the *Protoceratidæ*. We know absolutely nothing either of the ancestors or successors of this type; and this is another illustration of the fact which is constantly being impressed upon us, that our fossil-bearing strata still contain a great number of forms which are at present wholly unknown and unsuspected.

Henry F. Osborn.

HENRY F. BLANFORD, F.R.S.

Mr. H. F. BLANFORD, whose death was noticed in last week's Nature, was born in Bouverie Street, Whitefriars, in the City of London, in 1834. He was one of the students who entered the Royal School of Mines at its commencement in 1851, and after distinguishing himself by taking the first Duke of Cornwall's Scholarship, he studied for a year at Freiberg in Saxony. In 1855 he and his brother, Mr. W. T. Blanford, received appointments on the Geological Survey of India, and they landed in Calcutta at the end of September in that year. Mr. H. F. Blanford remained on the Geological Survey till 1862, when he resigned, his health having suffered from the exposure incidental to geological surveying in India. His most important work whilst engaged on the Survey was the examination of the cretaceous beds of the neighbourhood of Trichinopoly, his classification of which, founded to a considerable extent on palæontological data, has been thoroughly confirmed by Dr. F. Stoliczka's well-known description of the fauna. Mr. Blanford had previously, during his first season's work in India, by separating the Talchir strata, with their remarkable boulder bed, from the true coal-bearing, or Damuda rocks, taken the first step in what for so long was one of the most difficult tasks set before the Indian Geological Survey—the stratigraphical arrangement of the complex of beds subsequently known as the Gondwana system.

On leaving the Geological Survey he was offered a post in the Bengal Educational Department, and from 1862 to 1874 he was one of the professors of the Presidency College, Calcutta. Soon after 1862 he began to take a keen interest in meteorological questions, and after being for some time a member of a meteorological committee nominated by the government, he was, in April 1867, appointed Meteorological Reporter to the Government of Bengal, and placed in charge of an office established with a twofold purpose, to give storm warnings for the protection of shipping and to collect and record systematic meteorological observations throughout the Bengal presidency. Within a short time one most important result was obtained; the meteorological conditions under which cyclones originated in the Bay of Bengal were definitely ascertained, and it became practicable to say when a storm was a probable event, and in what part of the Bay it might be expected, and when a cyclone was impossible, although high winds might prevail. Meantime the various observatories of the country were being brought into order, and the observations rendered systematic.

In 1874 the Government of India became convinced of the necessity for placing all the meteorological observatories in India in communication with a central office, and Mr. Blanford was finally transferred from the educational staff of Bengal and made chief of the new meteorological department, with the official designation of Meteorological Reporter to the Government of India. The new post involved much travelling to visit out-stations, in order to ensure the exact comparison of barometers and other instruments. The organisation of the new department, however, progressed rapidly, and in a few years a series of papers from Mr. Blanford's pen on rainfall, wind directions, and other meteorological phenomena gave evidence to all interested in the science that valuable additions to it were being made by the Indian observations. The peculiar geographical conditions of India render its meteorology unusually simple, and of great scientific and practical importance. An admirable illustration, both of the peculiarity of Indian meteorology and of the practical results yielded by accurate observations, is afforded by the fact that no sooner was the whole system in working order, than it was found practicable some time before the commencement of the monsoon season, and of the rainfall, upon which in many provinces plenty or scarcity of food depends, to prepare a forecast of the approaching season, and to warn the Government of a possible deficiency of rain in particular parts of the country. The forecasts prepared have been found remarkably accurate.

Mr. Blanford retired from the Indian Service in 1888, and has since resided at Folkestone. Of late his health has gradually given way, and he died on January 23, at the age of fifty-eight. He was elected a Fellow of the Royal Society in 1880, and was an honorary member of several foreign meteorological societies. He was President of the Asiatic Society of Bengal in 1884–85.

That he was a man of considerable intellectual power is shown by the somewhat unusual range of scientific questions on which he has left works and papers. Besides his geological and meteorological reports, he wrote for the Indian Geological Survey descriptions of the *Nautilidæ* and *Belemnitidæ* of the South Indian cretaceous rocks, and he assisted the late Mr. J. W. Salter in describing the Palæontology of Niti. He was also author of several papers on recent mollusca; and amongst his works are two treatises, one on the "Physical Geography of India," largely used as a text-book in Indian schools, and the other "An Elementary Geography of India, Burma, and Ceylon," published as one of Macmillan's Geographical Series.

NOTES.

WE learn from Sydney that steady progress is being made with the Macleay Memorial Volume, and that it will probably be ready for issue about the end of March.

AN announcement comes from Chicago that Mr. Eadweard Muybridge, who, it will be remembered, visited this country some time since on behalf of the University of Pennsylvania, will give at intervals, from May to October, in the "Zoopraxographical Hall of the Exposition," a series of lectures on the science of animal locomotion, especially in its relation to design in art.

ON Thursday next, February 9, Prof. Patrick Geddes will begin, at the Royal Institution, a course of four lectures on the factors of organic evolution; and on Saturday week, February 18, Lord Rayleigh will begin a course of six lectures on sound and vibration.

A TRANSLATION of Prof. Weismann's new work on "The Germ-plasm," recently noticed in NATURE, will appear in the "Contemporary Science Series" in the course of a few weeks.

LAST week a deputation, representing the New Decimal Association, the Chambers of Commerce and Trades Unions, as well as various scientific institutions, waited upon Sir William Harcourt, Chancellor of the Exchequer, to urge the Government to adopt the decimal and metrical system of weights, measures, and coinage, or to appoint a committee of inquiry into the subject. Mr. S. Montagu, M.P., as president of the New Decimal Association, having introduced the deputation, said that forty years ago there was great apathy upon the subject, but since then there had been inquiries by Select Committees and Royal Commissions into the question of the decimal currency, and though the reports of those bodies were satisfactory, no action had followed. The system had been adopted in Germany, Austria-Hungary, and Scandinavia; and in England there was now a good popular demand, such as Mr. Goschen said six years ago he was waiting for. Men of science like Lord Kelvin, Sir Henry Roscoe, and Sir John Lubbock, and educationists like Sir Philip Magnus and Dr. Gladstone desired the reform in order to economise brain-power; representatives of commerce desired it to assist them in their competition with rival nations; and the working classes were awake to the fact that years of labour were wasted by their children being compelled to learn that which could be rendered unnecessary. Several members of the deputation, including Sir Philip Magnus, having spoken, Sir William Harcourt replied. He said that every one who reflected on the question must see the great advantages which attach to the decimal system. But the practical difficulties in the way of the proposed change seemed to him for the present to be insurmountable. A decimal system was introduced into Europe by the French Revolution. That was a time when the whole of society was cast into the melting pot, and they changed, not only their notation, not only their metrical system, but the names of the months and the days of the week. The change in Germany took place, not in quiet times, but as a result of the unification of Germany. He believed that even in the United States of America the change was made consequent upon the establishment of the Federal system. He did not think that the habits of the people could be altered in quiet times. This applied very much to the measures as well as to the coinage. Sir William was ready as an individual to play his part in forwarding the progress of the decimal system and the metrical system; but the Government could do nothing in the matter. The people would have to be prepared for so great a change.

IT is worth noting that instruction in the principles of the decimal and metric systems is daily given in public elementary schools, and that this labour—as Mr. J. H. Yoxall, secretary of the National Union of Teachers, has pointed out in a letter to the *Times*—is imposed upon the children without hope of practical good to the community. Mr. Yoxall contends that if an Act of Parliament were to fix a date of five or ten years hence at which the decimal system should come into legal operation, the work of the schools and the precaution of the mercantile classes would by that time sufficiently prepare the way.

A DESTRUCTIVE earthquake occurred on Tuesday morning at the town of Zante. Several houses were totally destroyed, many more were partially wrecked, and there is hardly a building in the town which has not sustained damage in one form or another. The roof of the prison collapsed during the earthquake, and the guards had to be doubled to prevent the escape of the prisoners. The hospital was also so seriously damaged that it was deemed expedient to remove the patients. The shocks, which were general, were renewed again and again, and the whole population was thrown into a state of panic.

DURING the past week the temperature over these islands has been fairly high, the daily maxima often exceeding 50°, notwithstanding a temporary fall, amounting from 12° to 14° in Scotland and the midland counties of England, on Friday, accompanied by much fog in the south and east of England, while the air has been decidedly humid, the readings of the dry and wet bulb thermometers frequently showing little or no difference. These conditions have been due to deep depressions arriving from the Atlantic and passing in close proximity to our western and northern coasts. In those parts gales have been of almost daily occurrence, and on Sunday they extended as far as the English Channel. Rain has been frequent, but generally the fall has not been heavy, and the sky has generally been overcast and dull, although on Saturday the weather over the south of England was unusually bright and fine. The *Weekly Weather Report* of January 28 shows that the temperature exceeded the mean in all districts, the greatest excess being 4° in Scotland. Bright sunshine also exceeded the mean in some parts of Scotland and in the eastern portion of England, but in other parts of these islands there was a deficiency.

A MAP showing lines of equal magnetic declination for January 1, 1893, in England and Wales, has been very carefully prepared by Mr. W. Ellis, and published as a supplement to the *Colliery Guardian* of January 6, 1893. The explanatory text states that, as before, the work depends on the magnetic surveys of Profs. Rücker and Thorpe. Mr. Ellis gives a table showing the relation between the diurnal variation of magnetic declination and sun-spots, as determined from the magnetic observations made at the Royal Observatory, Greenwich. The general mean at epochs of minima of sun-spots is 7·4 minutes, and at epochs of maxima 11·4 minutes of arc, and other magnetic elements show a similar relation. The period between successive epochs of maxima or of minima of sun-spots is well known to be on the average about 11 years, and the author points out the curious fact that the interval between the minimum and maximum is on the average 4½ years, whilst from maximum to minimum it is 7 years. The relation existing between sun-spot maxima and minima and the diurnal magnetic variation has led many meteorologists to seek for some similar connection with meteorological phenomena, but Mr. Ellis states that no such relation has yet been conclusively established.

THE report of the administration of the Meteorological Department of the Government of India in 1891–92 shows continued activity and efficiency in all departments of the work, and bears testimony to the interest taken both by the public and by the *employés*. The number of observatories maintained by the Government at the end of the year was 165. As regards the actinometric work, an unusual amount has been done, owing to the favourable state of the weather, and the results have been forwarded to the Solar Physics Committee in London. The rainfall data are published month by month, and a large number of unsatisfactory rain gauges has been replaced by new ones. A larger amount of work under the head of marine meteorology has been done than in any previous year; several clerks are continually employed in collecting data from ships entering the various ports, and these observations have been utilised in preparing daily weather charts of the whole Indian area for a portion of the year. The systems of storm and flood warnings have been continued as in previous years, and observations have been taken in certain forests, in order to throw light on the influence of forest growth in modifying the distribution and amount of rainfall; a report upon this subject will shortly be prepared. Among the other papers being prepared for publication we note one on the relation between sun-spots and weather as shown by meteorological observations taken on board ships in the Bay of Bengal during the years 1855 to 1878.

AT the meeting of the Royal Botanic Society of London on Saturday a plant of the Sisal hemp (*Agave rigida*) was shown from the Society's gardens. This plant is now extensively grown in the Bahamas and Central America for its fibre. The secretary said that until lately, with the exception of two or three fibre plants, as hemp and cotton, commerce depended upon wild plants for its supplies, but so great was the demand now for fibres for papermaking and other uses that it had been found necessary to grow them specially.

THE Slöjd Association of Great Britain met on Saturday to receive the annual report, to elect officers, and to appoint an examining body. It was agreed that "Sloyd" should be substituted for "Slöjd" in the name of the Association. The system of handiwork which the society is seeking to introduce into schools has already been pretty extensively adopted in this country, especially in the north of England. Mr. Harris stated at the meeting that it was being received with approval in many different parts of the world. He had received communications from Napier, New Zealand, and Lahore, India, as to its adoption in these places.

AN American writer who was present at the Galileo Festival in Padua gives a very interesting account of it in the New York *Nation*. He refers to the speeches delivered in Italian by Sir Joseph Fayrer and Prof. George Darwin, to which we have already alluded. "They were," he says, "much appreciated by the audience: 'Parla bene!' 'Pronunzia bene!' one heard murmured in tones not devoid of surprise." The greatest orator of the occasion, according to this writer, was Prof. Schmurlo of Dorpat, in Russia. "The type of the lonely and ungainly scholar in appearance, he nevertheless spoke a few phrases so ultra-Italian in the ingenious gracefulness of their turn, that the audience went fairly wild with delight."

THE latest instalment of the Transactions of the Institution of Engineers and Shipbuilders in Scotland contains an interesting paper, by Mr. E. G. Carey, on the bridges of the Manchester Ship Canal. The paper is fully illustrated. The author notes that practically the whole of the bridge-work for this canal has been constructed in Glasgow from Scotch steel.

THE Smithsonian Institution has issued as one of its bulletins a full and very useful bibliography of the published writings of George Newbold Lawrence, the well-known ornithologist. The work has been done by Mr. L. S. Foster, who gives also a short sketch of Mr. Lawrence's career. Mr. Lawrence's collection of bird-skins is of great scientific value. It includes about 8000 specimens, and contains some three hundred types of new species of birds. The collection was deposited in the American Museum of Natural History, New York City, in May 1887. Mr. Foster says that the beneficial influence of the labours of Mr. Lawrence, with pen and pencil, on the progress of American ornithology, has been great and undisputed. It is particularly among the avifauna of the West Indies, Mexico, Central and South America, that his most strenuous efforts have been exerted.

IF we may trust a statement made on the authority of the Tokyo News Agency, it is not surprising that Japan is unwilling to be deprived of the privilege of fishing on the Korean coast. The number of Japanese boats engaged in the fishery is said to be no less than upwards of four thousand four hundred, of which about eighteen hundred have licenses. Their annual take averages from a million and a half of *yen* to two million value, and it is estimated that with more diligence and improved methods they might easily bring this figure to three or four millions.

IT is rather surprising that tobacco has been so little cultivated in Australia. The *Agricultural Gazette* of New South Wales, we are glad to see, has taken up the matter, and in its November number devotes to it a comparatively long and interesting paper. The writer of the article thinks that the climate of New South Wales is admirably suited to the growth of tobacco, and hopes that a sufficient quantity of it may hereafter be produced not only to satisfy local demands, but to open up a large and lucrative export trade.

ONE of the curious survivals of ancient prejudices in India is the intense dislike with which many high caste Hindus regard sea-voyages. It is even disputed whether a Brahmin who takes a sea-voyage does not lose caste. The Maharaja of Mysore has not only emancipated himself from this strange notion, but is doing his best to overcome it in others. He lately made a voyage to Calcutta, and took with him a number of orthodox Brahmins, as well as Brahmin officials of state.

MR. WALTER HOUGH, of Washington, notes in *Science* that among the collections from Mexico, Central and South America, exhibited in the Columbian Historical Exhibition at Madrid, he observed a number of oblong polished blocks of hard stone of unknown use, averaging 3¼ inches in length, 2¾ inches in width, and 1¼ inches in thickness. The broad surfaces of these stones are plane, bearing a number of grooves parallel to the length, forming ridges like those seen on Polynesian tapa mallets. The implements resemble closely, he thinks, those used by many different peoples in beating out fibrous bark for clothing, paper, &c. Mr. Hough suggests that they may have been used for purposes of this kind in prehistoric times, and that they may give some insight into the manufacture of the paper on which the Mexican codices are painted.

MUD GORGE, on the Hurnai route to Quetta, has been giving much trouble to the engineers engaged in the construction of the new railway. Landslips are frequent, and an unusually bad one has occurred within the last few weeks. On this occasion the hill, according to the *Pioneer Mail*, slipped in such a way "as to lift the rails bodily up and turn them over, sleepers uppermost." The mountain is said to be a great porous mass of clayey soil with large boulders imbedded therein, and it sucks in moisture like a sponge. After heavy rain it begins to move downwards, and even in dry weather disintegration goes on with disastrous results to the railway. New fissures are reported to have appeared hundreds of yards up the slopes above the line, and each of these indicates that thousands of tons of earth and boulders will sooner or later find a lower level. A committee of experts has been appointed by the Indian Government to examine the mountain thoroughly, and the *Pioneer Mail* truly says that "if they succeed in devising a means to conquer it they will achieve a notable feat in engineering."

DR. LOW, President of Columbia College, New York, has been stating in the American *Educational Review* his impressions as to the condition and tendencies of the higher education in the United States. One of the points on which he strongly insists is that a general college training should be considered necessary before students begin their University education in theology, law, and medicine. "The prophetic eye," he says, "can even now discern the day when a college education will be a condition precedent for entrance into the professional schools of the American university. This will not mean that only college-trained men will make good practitioners in law or medicine, for example, nor that only college-trained men are entitled to a professional education. It will rather mean, I think, that the university will then have fully realised its own obligation to the country to send forth into professional life, in all parts of the land, men of a thorough and wide equipment."

ARCHÆOLOGISTS have observed that in Greek statues the male eye is strongly arched, while the female eye has rather a flattened surface; and referring to accounts by the older anatomists who have affirmed such a difference to exist, they have seen in this a fresh proof of the exact observation of nature by the ancient Greeks. The rule is not without exceptions, for the cornea in the Zeus of Otricoli has quite a flat form. Herr Greef recently set himself (*Archiv für Anat.*) to inquire whether such a sexual difference actually exists, and from individual measurement of the radius of the cornea in the horizontal meridian, he gets an average of 7·83 mm. for men, and 7·82 mm. for women (Donders gives 7·858 and 7·799), so the difference is so small as to be imperceptible to the naked eye. Measurement of other dimensions gave but minute differences also. The author concludes that the Greeks (from artistic motives) did not in this case follow nature.

THE difference between the aspect of the sky at full moon and the clear and deep azure observed on a moonless night is explained by M. Clémence Royer in his "Recherches d'Optique Physiologique et Physique" on the basis of some observations made by M. Piltschikoff. In studying the polarising action of the moon on the atmosphere, the latter found that the proportion of polarised light in the nocturnal sky diminishes continuously from the time of the full moon up to that of the new moon, when it becomes zero, subsequently to increase again until the time of full moon. There appears to be a struggle between the polarised light of the moon and the so-called natural light of the stars, and the proportion of polarised light sometimes reaches 62 per cent. The diffusing power of the atmosphere necessarily varies with the relative proportions of natural and of polarised light, since the latter is not capable of reflection in all directions. Hence we see why very serene but moonless nights may yet be relatively very clear, and the sky of a beautiful sombre blue, whereas the white light of the moon, reflected, diffused, and polarised, tends to give the sky a tint of a paler and somewhat greyish blue.

AT the last annual meeting of the American Association of Official Agricultural Chemists, the Proceedings of which have just been issued, Mr. N. T. Lupton referred in his presidential address to the immense phosphate beds in the south-western part of Florida. Last winter a visit was paid to some of the localities where deposits are found, and samples were collected for analysis. They were of two varieties, which may be called hard and soft. The hard variety consists of boulders of moderately hard rock, some of immense size, cemented together with white clay. A white and friable mass resembling kaolin is occasionally found. This is probably produced by the natural disintegration of the hard rock by rolling, attrition, or concussion. The deposits vary in thickness. A depth of 20 or 30 feet is not uncommon, and even a thickness of 50 feet has been found. As some, especially foreign, manufacturers object to buying phosphates which contain over 3 per cent. of oxides of iron and aluminium, large quantities of these materials have accumulated at the mines. A few manufacturers, aware of the agricultural value of South Carolina floats, have established mills in Florida for pulverising these soft aluminous deposits, which are sold to farmers for use without conversion into soluble phosphates. Experiments are now in progress on the Alabama Experiment Station, under control of the chemist, to determine the chemical composition and agricultural value of these soft phosphates when used alone with cotton seed and with cotton-seed meal. If decomposing organic matter, as is believed, renders insoluble phosphates available as plant food to any considerable extent, Mr. Lupton thinks that the question of cheap phosphates will be solved, and that the American farmer will be enabled to purchase fertilisers at a much less cost than at present.

MESSRS. W. H. ALLEN AND CO. have issued the thirty-seventh thousand of Dr. M. C. Cooke's "Manual of Structural Botany." The book is intended for the use of classes, schools, and private students.

THE February number of *Natural Science* includes, among other things, articles on some problems of the distribution of marine animals, by Otto Maas; on Pasteur's method of inoculation and its hypothetical explanation, by G. W. Bulman; the industries of the Maoris, by J. W. Davis; some recent researches on insect anatomy, by G. H. Carpenter; parasites on algæ, by G. Murray; the underground waste of the land, by H. B. Woodward; Owen (concluded), by A. S. Woodward; and the restoration of extinct animals.

THE following are the arrangements for science lectures at the Royal Victoria Hall during February:—Feb. 7, Mr. J. Scott Keltie, on Africa and its people; Feb. 14, Mr. E. Wethered, on interesting objects under a microscope; Feb. 21, Mr. J. T. Leon, on breathing and burning; Feb. 28, Dr. H. Forster Morley, on chemistry of life.

THE additions to the Zoological Society's Gardens during the past week include seven Azara's Opossums (*Didelphys azaræ*) from the Argentine Republic, presented by Mr. Hill; a Rough Terrapin (*Clemmys punctularia*) from Guiana, presented by Mr. J. J. Quelch, C.M.Z.S.; an American Milk Snake (*Coluber eximius*) from Tennessee, presented by Miss Winifred M. Middleton; a Virginian Eagle Owl (*Bubo maximus*) from South America, deposited; two Mouflons (*Orlis musimon*, ♂ ♀) from Corsica, received in exchange.

OUR ASTRONOMICAL COLUMN.

THE NAUTICAL ALMANAC FOR 1896.—The new superintendent of the *Nautical Almanac* office has introduced a much-needed reform into the first almanac, that for 1896, issued under his direction. The state of the *British Nautical Almanac* has long been severely criticised as being far from the best possible for navigational purposes both in form and contents, and by no means satisfactory from the astronomical standpoint. A letter addressed by the Shipmasters' Society to Dr. Hind, the late Superintendent, in November 1891, pointed out the advantage to navigators which would be offered by a work published at a popular price, and without that astronomical information which is of no use to sailors. Many low-priced almanacs are published, indistinctly printed, and having occasional errors in the figures, and an official trustworthy book was very desirable. In consequence of this representation the almanac is now published in two forms—as the complete almanac of former years, price 2*s*. 6*d*.; and as Part I. of the *Nautical Almanac*, specially suited for the use of sailors, price 1*s*.

The complete almanac has been revised and added to, many of the recommendations of the *Nautical Almanac* Committee of the Royal Astronomical Society, which reported to the Admiralty in 1891, having been adopted. The small short period terms of nutation have been tabulated, and, corresponding to that, additional day numbers are added so as to enable computers to include those small terms in the star corrections. The catalogue of stars from which the moon culminators and stars occulted by the moon are obtained has been revised and enlarged, and the mean places of the stars of this catalogue, which are used during the year, are also included. The elements of the occultations are given in a revised form similar to that adopted in most of the other astronomical ephemerides, so that the circumstances of an occultation for any position on the earth's surface can be computed with facility. There has been a general revision of the constants used.

The small almanac has been arranged by Mr. Downing in conference with the Hydrographer. As the guiding principle in publishing this was the minimum of change in the parts of the almanac which were to be extracted and published separately, there is still much in the volume that is not needed by sailors, but the omission of which would have necessitated the setting up of fresh type and much extra work at the *Nautical Almanac* office. The monthly part is printed unaltered, and consequently contains the sun's and moon's latitude and longitude, which are not required by sailors. The noon ephemerides for the brighter planets, Venus, Mars, Jupiter, and Saturn; the catalogue of mean places of stars, as well as the apparent places of the nine stars used for lunar distances; the eclipse section and the tables for navigation are then given. There is no doubt that the issue of this smaller work will confer a real benefit on the shipping community, and that it will soon win its way to popularity.

In announcing these changes to the Royal Astronomical Society, Mr. Downing expressed the hope of being able, through the economy of time effected by international co-operation in some of the work of the office, to make considerable future additions to the almanac without increasing the burden of the British taxpayer. The duplicate work done at Berlin, London, Paris, and Washington involves much waste of energy which might be more usefully expended: and as a step towards this, Mr. Downing, last summer, arranged with Prof. Newcomb, of Washington, to co-operate in some of the work of their respective almanacs, and the Admiralty have consented to this. It is to be hoped, in the interests of astronomy and of navigation, that the scheme may be greatly extended.

ECLIPSE PHOTOGRAPHY.—The results obtained by M. de la Baume Pluvinel at Salut Isles in 1889 (as given in his lecture which appeared in NATURE last week), when he photographed the corona with photographic actions varying from 185 to 13, and found the photographic action of 30 the most satisfactory; do not agree with those of the English expedition obtained at the same time and place. The photographic actions on the plates exposed with the 20-inch mirror of 45-inches focus, by the late Father Perry, varied from 19·75 to 790· as calculated by the formula given by M. de la Baume Pluvinel, and in every case increase of photographic action gave greater extension of the corona. Mr. Rooney's plates, with the 4-inch lens of 61 inches focus, had been subjected to photographic actions varying from 1·11 to 177·77, and agreed with Father Perry's in giving greater extension with every increase of photographic action. The English results certainly justify the conclusion that greater photographic action is necessary to photograph those faint extensions of the corona which have been seen, but have hitherto eluded attempts to photograph them.

Mr. Burnham's experiments, alluded to by M. Pluvinel, do not assist us in this question. A certain absolute amount of light is necessary to give *any* appreciable photographic effect on the plate, and this seems to be the chief difficulty in obtaining photographs of the external corona. In Mr. Burnham's experiments he had too much light and had to cut down the exposure in order to get faint contrasts, but there was never any question of not having sufficient light to obtain any photographic effect. Captain Abney finds (Phil. Trans. vol. clxxx. A, page 314) that an abrupt change of ½ per cent. in the intensity of light can be detected on a photograph, hence we may look upon a negative as a drawing built up of 200 different shades. Over exposure will of course prevent such faint contrasts as ½ per cent. being detected, and under exposure will enable fainter contrasts to be seen, *so long as the limit of minimum exposure necessary to produce any photographic effect is passed*; but the evidence from the English expedition renders it extremely probable that even with the largest photographic action used this limit was not actually reached with the faintest extensions of the corona.

COMET HOLMES.—Dr. F. Cohn, writing about this comet from the Observatory in Königsberg on January 17, finds (*Astronomische Nachrichten*, No. 3146), with a 6-inch heliometer and a magnification of 65 times, that the nucleus is exactly as a star of the 8th magnitude. The correction to the ephemeris given below is, as he has deduced, $\Delta\alpha = -0{\cdot}3$s., $\Delta\delta = -6''$.

Dr. R. Schorr, of the Hamburg Observatory, puts the nucleus down on the same date as a 7·2 magnitude star with a small nebulosity about it of 5″ diameter, but on the 18th he found the comet showed a much larger coma, a measurement giving 87″. The stellar nucleus was also estimated as 7·5 magnitude of a diameter 2″.

The ephemeris of this comet is from Prof. Schulhof's calculations (*Astronomische Nachrichten*, No. 3140):—

1893.	R.A. app.			Decl. app.		
	h.	m.	s.	°	′	″
Feb. 2	1	45	46·5	+33	49	26
3		47	16·6		50	48
4		48	47·3		52	14
5		50	18·6		53	45
6		51	50·4		55	20
7		53	22·8		56	59
8		54	55·8		58	41
9	1	56	29·3	34	0	28

COMET BROOKS (NOVEMBER 19, 1892).—The following is an ephemeris for Comet Brooks for the ensuing week:—

1893.	R.A. app.			Decl. app.		Log *r*.	Log Δ.	Br.
	h.	m.	s.	°	′			
Feb. 2	23	56	48	+34	27·7			
3	23	59	13	33	44·4	0·1050	0·1295	1·90
4	0	1	31	33	3·3

7		7	48	31	10·4			
8		9	43	30	35·8			
9	0	11	33	30	2·9	0·1167	0·1832	1·40

THE ANDROMEDES.—Although Mr. Maclair Boraston was unfortunate in having bad weather on the nights of November 13 and 14 last, thus obscuring the Leonids, yet the magnificent shower of the Andromedes that he describes in *Astronomy and Astrophysics* for January should have recompensed him somewhat for "the great elevation of the radiant point, combined with a cloudless tropical sky, the absence of moonlight and the unobstructed view of the complete hemisphere, afforded the *ne plus ultra* of astronomical requirement." Observing in longitude 72° west and latitude 17° north, between 11h. 48m. and 5h. 48m. G.M.T., he deduced the radiant point from 70 short-track meteors, and four coincident stationary ones, giving its position as R.A. 28°, decl. +36°. Counts being taken at intervals for areas of 60°, about 18 meteors per minute were recorded, thus making a total number of 108 for the entire hemisphere in one minute, or 6480 per hour. As this fall went on continuously for six hours without any sign of the numbers diminishing, we have the number of meteors 38,880, which Mr. Boraston says must certainly be a minimum, as many faint and rapid ones must have escaped notice. A further observation at 8h. 48m. showed that the action was still being kept up, thus increasing this number to about 60,000. During this display it was remarked that the meteors appeared much brighter when distant from the radiant point than in its vicinity.

A NEW METHOD OF PHOTOGRAPHING THE CORONA.—M. H. Deslandres, in the *Comptes Rendus* of January 23, describes a method of photographing the solar corona without the aid of absorbing media. Sunlight is allowed to fall directly on a system of two identical prisms with parallel and inverted faces placed at a distance apart, such that only a portion of the diverging band from the first is intercepted by the second. After passing through the latter, the rays by recomposition give rise to a well-defined coloured image of the sun's disc. On displacing the prisms in a line perpendicular to the line joining them, the image assumes different colours, and on moving them along it, the range of colours intercepted is made to change. The prisms may be replaced by gratings. In a series of experiments carried out during the autumn, nine successive impressions of the sun's image were taken, ranging from the C line till far into the ultra-violet. The object was to find the region where the light emitted by the corona showed the greatest photographic difference from that of the diffused sunlight in the atmosphere. As a matter of fact, a halo distinctly separated from the diffused sunlight showed itself on some of the negatives, especially in the ultra-violet region, which very probably represented the corona. But to confirm this, simultaneous exposures at different, especially elevated, stations ought to be made, if possible during a total eclipse.

GEOGRAPHICAL NOTES.

THE February number of the *Geographical Journal*, in addition to two important papers read before the Royal Geographical Society, and already reported in NATURE, contains a brilliant account by Mr. Conway of the crossing of the Hispar Pass. The views of mountain scenery were bewildering in their extent; from the foot of the valley an unbroken glacier was in sight, stretching downward from the pass forty miles distant. This unrivalled ice-stream was covered for the lower twenty miles with moraines. From the pass a vast snowfield, surrounded by magnificent rock aiguilles, was seen to lie below, and from this the Biafo glacier descended. From the end of the Hispar glacier to the end of the Biafo glacier was a distance of eighty miles, forming the longest snow-pass in the world outside the Polar regions. Mr. Stephen Wheeler communicates a paper on Mendez Pinto, whose early travels in the East seem to have been unduly discredited.

IT is announced that the eminent geographical author M. Elisée Reclus has accepted a professorship in the University of Brussels, and will commence his work there by a course of lectures on comparative geography.

MR. ASTOR CHANLER'S expedition to Lake Rudolf, by the Tana, has reached Hameye, the Ibea Company's post at the head of navigation on the Tana—a position accessible in five weeks from the coast, to which camels, oxen, donkeys, and horses can be safely taken. Lieutenant Höhnel, who is attached to the expedition, finds that Commander Dundas has placed the Tana from 20 to 22 minutes of longitude too far west, and he has searched in vain for the mountain ranges reported by Dr. Peters.

IN a recent journey of some duration in the Sakalava plain in the north-west of Madagascar, M. Emile Gautier (according to the *Annales Géographique*) found the soil everywhere to consist of a stiff red clay, weathered into steep-sided lumps and chasms overlying sedimentary rocks, but quite similar in colour and character to the red clay which covers the volcanic rocks of the plateau. M. Gautier believes that this clay is identical with the laterite of the Deccan.

MAJOR LEVERSON, the British Commissioner for the delimitation of the frontier between the British South Africa Company's territory and the Portuguese possessions, has returned to this country, after having carried out extensive surveys and made considerable rectifications in the map of a strip of country stretching from the north-east corner of the Transvaal northward to Massikesse. The position of the latter point was fixed as 18° 15′ 33″ S., 32° 51′ 24″ E.

MR. MACKINDER gave the second lecture of his course on History and Geography, under the auspices of the Royal Geographical Society, on Friday evening, when he discussed the road to the Indies, showing how the desert route, which led to the growth of Palmyra, was superseded by the ocean route after the successful rounding of the Cape of Good Hope. The theatre of history in ancient times was the region enclosed between the pine forests of northern Asia and the Indian Ocean, divided into separate worlds by a double belt of deserts and steppes.

THE GROWTH OF ELECTRICAL INDUSTRY.

ON Friday last Mr. W. H. Preece, F.R.S., delivered before the Institution of Electrical Engineers his inaugural address as President. He said he had completed his fortieth year of continuous service in developing the practical applications of electricity for the use and convenience of man, and it appeared to him that he could not better repay the high compliment the Institution had conferred on him by electing him, for the second time, to be its President than by surveying and criticising the growth of the various branches of electrical industry with which he had been more or less associated during that long period. In the course of his address he dealt with telegraphy, submarine telegraphy, lightning protection, railway signalling, telephony, domestic applications, electro-chemical industry, electric lighting, power transmission, electric traction, and theoretical views of electricity.

Speaking of telegraphy, Mr. Preece said:—The instrument that we have principally developed in England is the automatic fast-speed apparatus, based on a principle of preparing messages for transmission by punching, devised by Alexander Bain in 1848, and improved in its mechanical details by Mr. Augustus Ströh in 1866. This has been my special pet, and with the electrical assistance of Mr. J. B. Chapman, and the mechanical skill of Mr. J. W. Willmot, all the ills that telegraphs are heir to have been routed, and the practical speed of working has been multiplied more than six-fold. It has been one long continual contest between patient observation, inventive skill, careful experiment, and technical acquirement on the one hand, and resistance, electrostatic capacity, inertia (electro-magnetic and mechanical), bad insulation, impure materials, imperfect workmanship, &c., on the other. But we have, step by step, won all along the line: 75 words per minute have become 500; a possible 130 has become an actual 600. Duplex automatic working over cable lines is possible, and modes of working have been introduced that were thought at one time chimerical and impossible. . . .

The results to which I have referred have not been attained without very special attention to questions of construction and maintenance of the wires, both aerial and submarine, and a very complete system of test is now applied both before and after every line is completed. In the early days of telegraphic communication very rough and crude tests were applied, and the condition of the lines caused serious difficulties; but at the present day we must ascertain the purity of the metal employed, its mechanical strength, its electrical resistance and capacity, its insulation resistance, and the relationship between the latter and the conductor resistance, as well as its speed value. The employment of copper as the conductor suspended on poles in place of iron, which was inaugurated at my instigation in 1884, by a very costly experiment between London and Newcastle, has had a material influence in increasing the speed of working and improving telegraphy. This is due not only to its reduced resistance, but to the absence of electro-magnetic inertia in a long, single-suspended copper wire. All our long important telegraphic circuits are now built with copper.

One of the arguments used against the proposed transfer of the telegraphs to the State was the notion that invention would not be fostered by a Government department. This has been entirely falsified. Telegraphy has been advanced in this country more rapidly by the British Post Office than by any private undertaking, and we have certainly shot ahead of our smart cousins on the other side of the Atlantic, from whom, however, I am proud to say, I learnt so much on my visits in 1877 and 1884. Their engineers are looking to us to develop their inventions, and we have done so. They cannot always get them taken up in the States. Diplex, quadruplex, and multiplex telegraphy are importations from them, but they have been improved in our service by our own developments, and have now become the staple and the standard modes of working. No one has done more to effect this object than Mr. M. Cooper.

An accident in the drafting of the Act of Parliament of 1868-69 transferring the telegraphs from the hands of private companies to that of the State, has led to a tremendous development of newspaper reporting in England. Few people are aware of the immense business done for the press. The growth of press messages is shown in the fact that 21,701,968 words paid for in 1871 have grown in 1891 to 600,409,000—an average of nearly 2,000,000 words per day.

When Mr. Gladstone spoke at Newcastle, at the National Liberal Federation, in 1891, 390,778 words were signalled to different parts of the country. This kind of business is not, however, confined to the Post Office. The Exchange Telegraph Company, which commenced operations in 1872, working under the license of the Postmaster-General, has in London over 800 instruments at work (120 being in newspaper offices), distributing a daily average of 3,381,134 words to various receiving instruments adapted to the requirements of the respective services. The financial intelligence, for example, being transmitted over instruments furnished with type-wheels containing the various fractions most in use in Stock Exchange quotations. The latest form of this instrument prints at the rate of forty words per minute. General and parliamentary intelligence are distributed to the clubs over column printers, and legal, sporting, and Parliamentary news to newspapers on specially fast tape printers, capable of delivering, in the hands of skilled operators forty-five full words per minute to any number of subscribers simultaneously. The news transmitted is chiefly commercial and financial, amounting to 2,775,000 words per day.

To return to the purely State telegraphy. Some idea of the growth of the general telegraphic business of the country may be gathered from the following statement, which gives the total number of messages paid for in each year:—

1852	211,137
1869	6,830,000
Transfer took place in 1870.	
1882	31,345,861
1892	70,215,439

In the course of his review of the history of submarine telegraphy, Mr. Preece said:—By far the greatest cable corporation in the world is the Eastern Telegraph Company, whose system of 25,376 miles stretches from Cornwall to Bombay, connects the northern and southern shores of the Mediterranean with Malta, and joins up the various other islands of the Mediterranean and the Levant. This company, in conjunction with the Eastern Extension and the Eastern and South African Companies, also gains access to Australia and New Zealand on the one hand, and to the Cape of Good Hope on the other, the combined mileage reaching a total of no less than 47,151. This enormous system has all grown up within, practically, the last 23 years.

The form of cable has practically remained unaltered since the original Calais cable was laid in 1851. Various sizes of core and armour, and various modes of protection from decay, have been used to suit different routes, but the cable of to-day may be said to be typically the same as that used in the English Channel in 1851, and in the Atlantic in 1865.

The first cable had gutta-percha as a dielectric, and it is still almost exclusively used for submarine cable core; but the manufacture has so improved in the last twenty years that a core having an insulator weighing 150 lbs. per naut, which then had a dielectric resistance of some 250 megohms a naut at 75° F., can now be obtained, giving 2000 megohms at the same temperature. Indiarubber is creeping in, owing to the high price and scarcity of gutta-percha.

Next to strong tides, rocky bottoms, anchors, and shallow water, the greatest enemy to submarine cables, more especially in the tropics, has proved to be the teredo of various species; but this depredatory worm has been utterly routed by covering the gutta-percha core with a lapping of thin brass tape laid on spirally. A remarkable thing about this little insect is that, whereas twenty years ago it was practically unknown in our English waters, it has now gradually spread all round our coasts, with the exception, perhaps, of the North Sea. A new cable about to connect Scotland and Ireland is being served with brass tape.

With the cables has grown up a fleet of telegraph ships to lay and maintain them. In 1853 the *Monarch*, belonging to the Electric Telegraph Company, was the only ship permanently employed as a repairing telegraph ship; now, in 1893, the cable fleet of the world numbers no less than 37, of which seven belong to Government administrations and the rest to private companies, the Eastern Telegraph Company heading the list with five vessels.

Perhaps the most remarkable history of a cable is the following:—In 1859 the light cables laid in 1853 from Orfordness to Holland were picked up and replaced by a heavier one. A few nauts were sold to the Isle of Man Telegraph Company, and had an extra sheath laid on. This cable was submerged between that island and St. Bees, where it remained until 1885, when it was replaced by a three-core cable. It was again put under water in 1886 as part of the cable between Uist and Harris, in the Hebrides, where it still lies, as good as ever. The durability of submarine cables is remarkable. That laid between Beachy Head and Dieppe in 1861 is still working; and that laid between Beachy Head and Havre in 1870 has broken within the last month for the *first* time.

Despite the enormous growth of submarine cables during these forty-two years, there would appear to be plenty of scope for still further extension. The Pacific still remains untouched, and the project is at the present time under consideration to connect our possessions in North America with those in Australia.

The following is the passage relating to telephony:—I had the good fortune in 1877 to bring to England the first pair of practical telephones. They had been given to me in New York by Graham Bell himself. After a series of experiments, I brought them before the British Association meeting, which was held that year at Plymouth. Who at that time could have imagined that the instruments, which were then but toys, would, within sixteen years, have become a necessity of commercial, and almost of domestic, life? Yet to-day the number of telephones in actual use may pretty safely be put down at a million!

During 1878 Edison devised his carbon transmitter, and Prof. Hughes presented his "microphone" to the world. These inventions made the telephone a practical instrument of vast commercial importance. It may be said to have sprung into existence well-nigh perfect; and the fewness of the actual improvements on the Bell receiver and the Hughes microphone is scarcely more astonishing than the immense number of fruitless attempts at improvement that have been made. Even now the original instruments are not easily beaten.

The institution of telephone exchanges has led to a development of systems of switching that might fairly be considered a special study in themselves, and the demand for communication between distant places has necessitated the application of much special attention to the method of constructing lines and of arranging circuits.

It is in this latter field that I have been a diligent worker, and the application of the so-called "K R" law has proved of material benefit in connection with the problems of long-distance telephony. It is a law which implies that the number of signals that can be transmitted per second through any circuit depends solely on the capacity (K) and the resistance (R) of the circuit. It is very much the fashion to deny the accuracy of the K R law. This is probably the result of ignorance of its meaning or of its interpretation. Some speak of it as empirical, others scoff at it as imaginary, and some sneer at it as an impossible law; but it is a law that has determined the dimensions and speed of working of all our long submarine cables; it determines the number of arms a circuit can carry on the multiplex system, the speed attainable with the Wheatstone system, and the distance to which it is possible to work quadruplex; it is a law that has enabled us to bring London and Paris within clear telephone speech of each other, and which will probably before the year is out enable Dublin and Belfast to speak to London—a message of peace to Ireland as solid and substantial as any promised political proposal.

The New York and Chicago trunk line is 950 miles long, and it is built with 435 lbs. (or No. 8 S.W.G.) copper wire. This wire gives a resistance of 2·06 ohms per mile, which is easily verified; but it is said by Mr. Wetzler to have a capacity of 0·0158 microfarad per mile, which cannot be verified, and which is absurdly high. 0·0158 microfarad was a measurement made by me in England on an old line, but I have frequently pointed out that owing to the use of earth wires the capacity of our English lines is very much greater than that of American lines. Mr. Edison discovered this in 1872 when he came to England to introduce his automatic system. Moreover, I have also pointed out that induction still further diminishes this capacity. The Paris circuit does not exceed 0·005 microfarad per mile. I should estimate the Chicago circuit at 0·004 microfarad per mile, and the K R at 7500, which gives a result that quite accords with the opinions that I have heard expressed by those who have tried the two circuits as to the relative efficiency of the Paris and Chicago lines. My American friends would have done better if they had used thicker wire. I should have specified 600 lbs. per mile; but if it had been in England I should have used 1000 lbs., for we cannot dispense entirely with cables and underground work as they have done in the States, and the increased capacity introduced must be compensated for by reduced resistance. As a matter of fact, I once proposed 1200 lbs. wire for a circuit between London and Berlin—a distance of 760 miles, including a cable 55 miles long.

The beneficial effect of induction as a negative capacity is observed when working a circuit telegraphically with automatic high-speed apparatus. Thus, on two copper wires 450 miles long, making 900 miles altogether, the speed on each single wire was 120 words per minute, and on metallic circuit—

Loop *viâ* different routes ... 120 words per minute.
,, on same poles ... ... 150 ,, ,,

So that the improvement effected by induction was 25 per cent.

There is no difficulty in measuring R of a metallic loop. The Wheatstone bridge determines it at once. There is more difficulty in obtaining K. It cannot be measured directly. But with a metallic loop of copper, partly overhead and partly underground, there are several modifications required, due to electrostatic and electro-magnetic induction, which are at present beyond the reach of formulæ, and render it difficult to determine the capacity except approximately from the telephonic effects themselves. Thus the capacity on the London-Paris circuit proved to be only one-half of that obtained by calculation, and every long circuit will require its own K to be determined by comparison with an empirical K R scale. Such a scale I have determined by careful experiment on artificial cables.

I have recently devised a new form of cable which will probably quadruple the rate of telegraph working to America; and I may say with all confidence that there is no theoretical reason whatever why we should not converse between London and every capital in Europe, while it is not impossible to speak even across the Atlantic.

With regard to electric lighting, Mr. Preece said that many efforts are being made to utilise the waste forces of nature in producing electric currents for the economical supply of the light. In America, Scotland, Switzerland, Italy, and, indeed, wherever waterfalls are available, electric plant is being installed to convert the energy of the fall into the useful form of electricity. At Tivoli, near Rome, a fall of 165 feet is used to work six turbines of 350 horse-power each, giving 2100 horse-power in all. Six high-pressure alternators working in parallel send electrical energy at over 5000 volts pressure to Porta Pia, near Rome, 14·8 miles from Tivoli, through four stranded copper conductors, each having a diameter of 13mm., and bunched into one metallic loop, giving a total resistance of 4 ohms. At Porta Pia the 5000 volts are reduced to 2000, and the currents are distributed to several substations spread over the city, where they are again lowered to the safe pressure of 102 volts, at which voltage the current is supplied to the consumer on the three-wire system. There are 600 arcs and 30,000 glow lamps in use in Rome, but they are not all supplied from Tivoli. Mr. Preece inspected this installation only a few days ago, and found everything working smoothly and efficiently under the able guidance of Prof. Mengarini.

Water power abolishes the coal bill, but it must be remembered that the cost of maintenance of machinery and of the erection and upkeep of conductors limits the distance to which the energy of falling water can be economically transmitted. The proposal to light New York by currents generated at Niagara is at present financially absurd. It is doubtful whether it will be commercially advantageous at Buffalo, 30 miles away, but it is certain that at Tivoli it can be so applied with advantage and profit.

There is much water power in this country that might be usefully employed. At Worcester it is proposed to use the water of the Teme, a tributary of the Severn, to supply electrical energy to the city—an experiment that will be watched with considerable interest, for the use of water power will solve the difficulty occasioned by light loads during the small hours and daylight. Keswick and Lynton have already been so served, but on a small scale only. There are many towns whose public streets could be brilliantly illuminated by the streams running past them, but there is much fear and distrust to be removed from the minds of our local magnates, and a considerable amount of education necessary before the public will receive the full value of the gifts that nature so freely places at its disposal, and the engineer so thoroughly converts into a utilitarian form.

The following are some extracts from the passage in which theoretical views of electricity are discussed:—

In the Presidential address which I delivered to the Society of Telegraph Engineers and Electricians in 1880, I took the opportunity to formulate the theoretical views of electricity that I had acquired at the feet of Faraday. It is not given to every boy to have his great ambitions realised. One of my ambitions as an earnest listener to Faraday's simple and delightful lectures was to be his assistant, and in almost the last investigation he undertook on electric induction in underground wires it was my privilege to see much of him, and to prepare many experiments for him. Early in 1854, at his wish, I carried out for Mr. Latimer Clerk certain experiments on the comparative effect of increments of voltage in increasing the rate of transmission of signals through long telegraph circuits. It was found that variation of voltage had no effect. Currents from 31 and from 500 cells sent through 768 miles of gutta-percha-covered underground wire showed precisely the same velocity. These experiments were sent by Faraday to Melloni, who had prompted the wish, and Melloni ("Faraday's Researches," vol. iii. page 577) remarked: "The equal velocity of currents of various tensions offers a fine argument in favour of the opinion of those who suppose the electric current to be analogous to the vibrations of air under the action of sonorous bodies." This is to be found in the very last contribution inserted in the greatest work ever published on our science, "Faraday's Experimental Researches in Electricity."

Faraday's views were subsequently expounded and extended by Maxwell, who said: "Faraday, in his mind's eye, saw lines of force traversing all space, where the mathematician saw centres of force attracting at a distance; Faraday saw a medium where they saw nothing but distance; Faraday sought the seat of the phenomena in real actions going on in the medium, they were satisfied that they had found it in a power of action at a distance impressed on the electric fluids" (Maxwell, "Electricity," vol. i. page 10).

Since that period I have never regarded electricity as anything else but as a form of energy, and its effects as modes of motion of the molecules of matter and of the ether that fills all space; and during my long apprenticeship of forty years I have never examined one experiment or considered one fact that was not explicable on this theory. . . .

Electricity is energy which is transmitted by matter and through space by certain disturbances the result and the equivalent of work done, and in certain orderly and law regulated forms, called "electro-magnetic waves." It is not difficult to conceive the ether carved or the molecules of matter swayed or excited in definite periodic waves. A molecule is subject to all kinds of motion—translation, oscillation, rotation upon its own axis, and revolution about some external axis. Clausius (*Pogg. Ann.*, clvi. p. 618) suggested that the atoms or groups of atoms constituting a molecule revolve around one another similarly to planets, and are sometimes nearer to and sometimes further from each other. The difference between the infinitely great and the infinitely little is only one of degree. The motions of the solar system and that of a molecule of water are similar. These motions are imparted to and transmitted by the ether, and they are taken up again by matter. One kind of wave gives us light, another radiant heat, another magnetism, and another electrification. The rate at which these waves move is the same, viz. 30,000,000,000 centimetres, or 192,000 miles, per second. It is only their form and their frequency that differ. Matter and ether are subject to strains, currents, vortices, and undulations, and every single electro-magnetic phenomenon can be compounded of or reduced to one or other of these mechanical disturbances. Rotation in one direction gives positive electrification: rotation in the opposite direction gives negative electrification. A whirl in one direction gives us north magnetism; in another direction, south magnetism. Hertz, the experimental exponent of Maxwell's views, has shown the existence of electro-magnetic waves, and has proved their reflection, refraction, and interference. The rate of their propagation is the same in ether, air, and conducting wires.

The most recent discoveries and deductions are all in accordance with this mechanical theory. J. J. Thomson's views that at high temperatures, in the act of dissociation, all gases, and Dewar and Fleming's conclusion that at low temperatures—in fact, at the absolute zero of temperature—all metals become perfect conductors, might almost have been predicted. Hysteresis and Foucault losses are mere wastes of energy, due to molecular friction or to internal work done on the molecules, assisted by bad design and impure material; but, being measurable and comprehensible, their reduction to a minimum has become possible and actual.

It is a misfortune that a beautiful hypothesis like Maxwell's electro-magnetic theory of light has been discussed almost solely by mathematicians. Its consideration has been confined to a small and exclusive class. It has not reached the public; and this is to be regretted, for, after all, it is the many, and not the few, that determine the acceptance or refusal of a theory. The existence of the ether is now thoroughly comprehensible. Light is now regarded as an electro-magnetic disturbance. The eye is an extremely sensitive and delicate electro-magnetic instrument. The difference between luminous, thermic, and electro-magnetic waves is one of frequency and form. We thus have to consider the propagation of these waves not only in the conductor and in the dielectric in the direction of the circuit itself, but in the ether at right angles to this direction. The former produces currents in the conductor, and the latter induction and secondary effects in contiguous conductors. Thus it is easy to see why electric and magnetic lines of force are at right angles to each other, and each of them perpendicular to the line of propagation of the primary electro-magnetic wave, and why the transversal disturbances are secondary waves of electro-magnetic energy which can be transformed into electric currents of opposite direction whenever contiguous conductors lie in their path so as to be cut by these lines of force in the proper direction. Induction is thus mere transformation of energy whose direction and magnitude are easily calculated.

It is by following out this line of thought that I have recently succeeded in sending messages by Morse signals across the Bristol Channel between Lavernock and Flat Holm, a distance of 3·1 miles. The electro-magnetic disturbances were excited by primary alternating currents in a copper wire, 1237 yards long, erected on poles along the top of the cliff on the mainland. The radiant electro-magnetic energy was transformed into currents again in a secondary circuit, 610 yards long, laid along the island. The strength of these secondary induced currents complied almost exactly with calculations. The results attained, the apparatus used, the precautions taken to separate effects of induction from effects of conduction; the elimination of mere earth currents from electro-magnetic disturbances in air, will form the subject of a separate paper, for their proper consideration would be too tedious for an address. I allude to them now only to illustrate the existence of one of the greatest proofs of the truth of a theory, viz. the practical development and verification of a conclusion predicted from mere theoretical considerations.

The oscillatory character of the discharge of a Leyden jar, which was discovered by Henry in 1842, is an admirable proof of this molecular theory. If two jars, precisely similar as regards capacity and circuit inertia, be placed near each other with their planes parallel, and one of them is charged and discharged, the other responds sympathetically, as do two similarly pitched tuning-forks when one is excited. Professor Oliver Lodge, who has made this field his own, has shown that by varying the capacity of the jars and the inertia of the circuit, oscillations can be produced to give any required rate of oscillation from one to 300 millions per second.

In a room or theatre, when these discharges are excited, it is a common thing to see sympathetic sparks upon the spangled walls, and among the metallic objects scattered about. The whole place is an electric field, which is violently disturbed at every spark, and everything which is "syntonised," as Oliver Lodge calls it, to the main discharge, responds in this way.

It is impossible to account for these effects, which are all cases of transformed kinetic energy, except on the mechanical theory which I have advanced. We have a source of disturbance, we have energy transmitted in waves, we have wave transformed into disturbance again. Energy passes through its various stages by the motion of matter and the action of the ether. Everything is accounted for and nothing is lost. Waste energy only means energy in the wrong place.

YEZO AND THE AINU.

TWO papers on recent travels in the Island of Yezo were read to the Royal Geographical Society on Monday evening. Prof. J. Milne, F.R.S., whose paper was read by the Secretary, made a journey to the north-east of the island by sea in 1891, and returned by land, crossing Yezo almost through its centre. He was accompanied by Mr. John Revilliod, and travelled with a view to studying the volcanic geology of the regions. Landing at Kushiro, interesting on account of the relics of pre-Ainu inhabitants, and on account of its coal mines, they ascended the Kusuri river to Shibecha, where there is a great convict prison and sulphur refinery, the raw sulphur being obtained from the volcano Atosanobori, to which there is a railway twenty miles long. In this locality the violence of the escape of steam from the boiling springs exceeds anything seen elsewhere in Japan, New Zealand, or Iceland. A new road, thirty-seven miles long, led from the volcano to Apashiri, on the north-east coast, where a factory for making matches has recently been erected, on account of the abundance of the white-stemmed poplar, the timber of which is much more readily worked in the fresh state than when dried. A boat journey was made in a small dug-out canoe under rugged cliffs from 500 feet to 1000 feet in height, for thirty miles to Shiritoki, where there is a great sulphur mine. From some of the volcanic craters fused sulphur flows like lava, and crystallises in an almost pure state. A trip from Nemuro to the nearer Kurile Islands was followed by the main feature of the journey, a ride from Yubets, on the north coast, up the Yubets river, across the watershed, and down the Ishikari river, to the west coast. Groups of convicts working on the new roads, which are being made across the island, were almost the only people met with. Vast groves of tall bamboo grass everywhere impeded the travellers, and insects of all kinds proved very troublesome. There was little or no sign of larger animal life.

Mr. A. H. Savage Landor also read a paper. He had wandered all round Yezo and up several of the largest rivers quite alone, and with no object save curiosity and the desire to study the Ainu at home. The main part of his equipment was a great store of painting material, of which he made good use in portraying both the natives and the scenery of the island. The Ainu accessible from Hakodate, who have been frequently visited and often described, are almost all Japanese half-breeds, and much influenced in customs and costume by their southern neighbours. The Ainu of the interior and the more distant parts of the coast were very different. The true Ainu villages are intensely filthy, and the vermin in them make life almost unsupportable to a stranger, minute black flies, which swarm in incredible hosts, being the worst. The people, although good-humoured, are sunk in the most degraded savagery. Their marriage customs seem to be summed up in unqualified promiscuity, the Ainu disclaiming any idea of being better than bears or dogs. The Ainu language is poor in words, and many of them show a curious resemblance to words of Anglo-Saxon origin, *e.g. Chip*, for ship; *Do*, day; *Mukku*, music; *Pone*, bone; *Ru*, road; *To*, two; *Wakka*, water. The religious beliefs of the Ainu can hardly be dignified by such a term; they are merely superstitions. In travelling along the south-west coast there was often considerable danger from the waves washing over the narrow track which wound between the boulders on the beach. Fog prevails along the east coast in summer, probably on account of the Kuro-Siwo encountering a cold current off the island. The upper Tokachi river was the most remote part of Yezo visited, a region which had scarcely been traversed by the Japanese. Here the Ainu were found to be more hairy than elsewhere, and to present many Aryan features in their general appearance. One peculiar fact brought out by many measurements was the remarkable length of their arms. The measurement across the outstretched arms is always from three to five inches more than the height of the individual. The future capital of Hokkaido (the name given to Yezo and the Kurile Islands collectively) is to be erected on the Kamikawa plain, in the very centre of Yezo, and roads are being pushed forward to connect it with all parts of the coast. It will, when completed, take the place of the present capital, Sapporo. According to Japanese maps, Mr. Landor's journey extended to 5000 miles, but his own reckoning puts it as 3800; almost the whole distance was done on horseback.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—By the death of Prof. Westwood on January 2 the University lost one of the most learned of its members, and another link with the earlier study of science in Oxford is gone. Prof. Westwood became Hope Professor on the foundation of the chair by the Rev. F. W. Hope in 1861, and afterwards devoted his time to the perfecting of the collection which Mr. Hope bestowed on the University. The collection, which has received considerable additions from other sources, including the Burchell collection, Wallace's types, &c., has attained somewhat unmanageable proportions, and its present quarters are too small for its proper display. Whoever succeeds to the chair, it is to be hoped that suitable provision will be afforded to enable him to make the collection of more use to University studies than has hitherto been the case.

In November last an examination for a Radcliffe Travelling Fellowship, thrown open, *pro hac vice*, to all branches of natural science, was held, but the result has not yet been announced. It is now announced that an examination will be held during this term for a second Radcliffe Fellowship, the subjects being strictly medical. It is believed that the results of the two examinations will be published together at the end of this term. There is some dissatisfaction at the delay in announcing the result of the first examination.

Prof. Ray Lankester has recovered from the illness which necessitated his absence from Oxford last term, and has resumed his lectures on the Vertebrata and a senior course on the Arachnida.

The Mathematical Scholarships and Exhibitions have been awarded as follows:—

Senior Mathematical Scholar, R. C. Fowler, B.A., of New College.

Proxime Accessit, S. F. White, B.A., of Wadham College, to whom the Examiners have awarded Lady Herschell's book.

Junior Mathematical Scholar, C. B. Underhill, Balliol College.

Junior Mathematical Exhibition, J. F. McKean, Hertford College.

Proxime Accessit, W. C. Childs, Corpus Christi College.

The Duchess of Marlborough has bestowed on the Chemical Department the entire collection of chemical and electrical apparatus belonging to the late Duke. The collection, which includes two exceptionally fine spectroscopes, delicate balances, &c., has been brought to the Museum from Blenheim, and forms a valuable addition to the Chemical Laboratory.

Mr. E. L. Collis, of Keble, is President, and Mr. M. D. Hill, of New College, is Treasurer of the Junior Scientific Club this term, and Messrs. C. H. H. Walker, of University College, and T. H. Butler, of Corpus Christi, are respectively Chemical and Biological Secretaries. The first meeting is held on Wednesday, February 1, when Mr. J. E. Marsh exhibits some products of the electrical furnace, and Messrs. Finn and Fremantle read papers on East Africa and Hermaphroditism.

At a meeting of the Biological Club, on Saturday last, Mr. G. C. Bourne read a paper on the influence of the nucleus on the cell.

CAMBRIDGE.—The Senate have resolved to appoint a Demonstrator in Palæozoology in connection with the Geological Department. He will have no stipend from the University, but will be remunerated from the fees paid by students.

Dr. Allbutt, Regius Professor of Physic, Dr. A. MacAlister, Professor of Anatomy, and Dr. Donald MacAlister, University Lecturer in Medicine, have been appointed to represent the University at the Eleventh International Medical Congress to be held at Rome in September next.

Dr. W. H. Gaskell has been appointed a member of the Special Board for Medicine, and Mr. C. T. Heycock a member of the Special Board for Physics and Chemistry. Dr. Ransome, F.R.S., Honorary Fellow of Gonville and Caius College; Dr. Corfield, F.R.S, Professor of Hygiene and Public Health in University College, London; Dr. J. Lane Notter, Professor of Military Hygiene at Netley; and Dr. Thorne Thorne, F.R.S., Medical Officer to H.M. Local Government Board, have been appointed Examiners in State Medicine for the Diploma in Public Health during the current year.

Sir G. G. Stokes and Dr. Hobson have been elected Examiners for the Adams Memorial Prize to be awarded in 1895.

Mr. E. H. Acton, of St. John's, and Mr. T. H. Easterfield, of Clare, have been approved as Teachers of Chemistry with reference to the regulations for medical and surgical degrees.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 15, 1892.—"Experiments on the Action of Light on *Bacillus anthracis*." By Prof. Marshall Ward, F.R.S.

It is abundantly evinced by experiments that direct insolation in some way leads to the destruction of spores of *Bacillus anthracis*, and in so far the results merely confirm what had already been discovered by Downes and Blunt in 1877 and 1878.[1]

From the fact that an apparent retardation of the development of the colonies on plates exposed to light was observed several times under circumstances which suggested a direct inhibitory action of even ordinary daylight, the author went further into this particular question with results as startling as they are important, for if the explanation given of the phenomena observed in the following experiments turns out to be the correct one, we stand face to face with the fact that by far the most potent factor in the purification of the air and rivers of bacteria is the sunlight. The fact that direct sunlight is efficacious as a bactericide has been long suspected, but put forward very vaguely in most cases.

Starting from the observation that a test-tube, or small flask containing a few c.c. of Thames water with many hundreds of thousands of anthrax spores in it may be entirely rid of living spores by continued exposure daily for a few days to the light of the sun, and that even a few weeks of bright summer daylight —not direct insolation—reduces the number of spores capable of development on gelatine, it seemed worth while to try the effect of direct insolation on plate-cultures to see if the results could be got more quickly and definitely.[2]

Preliminary trials with gelatine plate-cultures at the end of the summer soon showed that precautions of several kinds were necessary. The direct exposure of an ordinary plate-culture to the full light of even a September or October sun, especially in the afternoon, usually leads at once to the running and liquefaction of the gelatine, and although the exposed plates eventually showed fewer anthrax colonies than similar plates not exposed, the matter was too complicated to give satisfactory results. Obviously one objection was that the spores might have begun to germinate, and the young colonies killed by the high temperatures.

Experiments made in October with gelatine plates wrapped in black paper, in which a figure—a square, cross, or letter—was cut, also led to results too indefinite for satisfaction, although it was clear in some cases that if the plates lay quite flat, the illuminated area was on the whole clear of colonies, while that part of the plate covered by the paper was full of colonies.

But another source of vexation arose. After the plates had been exposed to the sunlight for, say, six hours, it was necessary to put them in the incubator (20°–22° C. was the temperature used) for two days or so, to develop the colonies, and in many cases it was observed that by the time the colonies were sufficiently far advanced to show up clearly, liquefaction had extended so far as to render the figure blurred and doubtful.

---

[1] See p. 237 of "First Report to the Water Research Committee of the Royal Society" ("Roy. Soc. Proc." vol. 51, 1892) for the literature on this subject up to 1891.

[2] It appears that Buchner (*Centr. f. Bakt.* vol. xii. 1892) has already done this for typhoid, and finds the direct rays of the summer sun quite effective.

Stencil plates of zinc were employed with, at first, equally uncertain results. The stencil plate was fixed to the bottom of the plate culture, outside, and every other part covered with blackened paper: the plate was then placed on a level surface, the stencil-covered face upward, and exposed to the direct sunlight. As before, the gelatine softened and in many cases ran, and the results were uncertain, though not altogether discouraging.

In November it was found that more definite results could be obtained, and the problem was at last solved.

Meanwhile it had already been found possible to obtain sun prints in the following way with agar plates. Ordinary agar was heated and allowed to cool to between 50° and 60° C., and was then richly infected with anthrax spores, and made into plates as usual. Such plates were then covered with a stencil plate on the lower face—the stencil plate being therefore separated from the infected agar only by the glass of the plate—and wrapped elsewhere closely in dull black paper, so that, on exposure to the sun only the cut-out figure or letter allowed the solar rays to reach the agar.

Such plates were then exposed to the direct rays of the October sun for from two to six hours; or they were placed on the ring of a retort-stand, stencil downwards, and the sunlight reflected upwards from a plane mirror below.

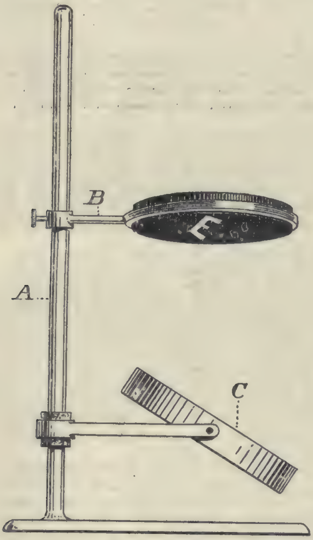

Fig. 1.

After the insolation these plates were incubated for at least forty-eight hours at 20° C., and on removing the wrappers the colonies of anthrax were found densely covering all parts of the plate except the area—a letter or cross, &c.—exposed to the sunlight. There, however, the spores were killed, and the agar remained perfectly clear, showing the form of a sharp transparent letter, cross, &c., in a groundwork rendered cloudy and opaque by the innumerable colonies of anthrax.

Experiments proved that this was not due to high temperature, for a thermometer with its bulb next the insolated glass rarely rose beyond 14° to 16° C., and never beyond 18° C., and even if the thermometer did not record the temperature inside the plate, this can scarcely have been much higher.

As long as this latter point remained uncertain, however, the experiments could not be regarded as satisfactory; whence it was necessary to again have recourse to gelatine cultures. The gelatine employed began to run at 29° C., and in November it was found that such plates exposed outside, either to directly incident sunshine, or to directly reflected rays, showed a temperature of 12° to 13° C. at the insolated glass surface, and even five to six hours exposure caused no running of the gelatine.

The following experiment may be selected as a type of the rest:—A (Fig. 1) is the upright of an ordinary retort-stand; on the ring B rested a gelatine plate culture of anthrax spores, covered with black paper everywhere except the cut-out letter E, seen on its lower face. C was an ordinary plane microscope-mirror with its arm fitted to a cork on A.

The whole was placed in the middle of a field at 9.30 a.m. on Wednesday, November 30, and exposed to the clear, but low, sunshine which prevailed that day, the mirror being so arranged (from time to time as necessary) as to reflect the light on the E the whole period, until 3.30 p.m., when the plate was removed and placed in the dark incubator at 20° C. On the following Friday—*i.e.* after less than forty-eight hours' incubation—the letter E stood out sharp and clearly transparent from the faint grey of the rest of the plate of gelatine. Not a trace of anthrax could be found in the clear area, even with the microscope, while the grey and almost opaque appearance of the rest of the plate was due to innumerable colonies of that organism which had developed in the interval.

It was impossible to incubate the plate longer for fear of liquefaction, whence the sceptical may reply that the anthrax exposed to light was only retarded; the experiments with agar show that such is not the case, however, and that if the insolation is complete the spores are rendered incapable of germinating at all, as proved by removing pieces of the clear agar or gelatine and attempting to make tube cultures from them: in all cases where insolation is complete they remain sterile.

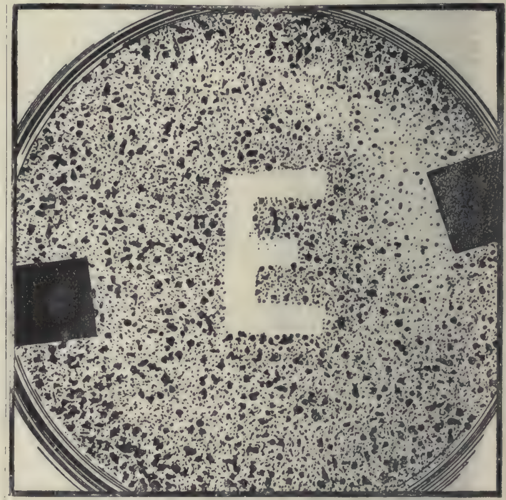

Fig. 2.

The chief value of these gelatine plate exposures in November, however, is that they prove conclusively (1) that the rays of a *winter* sun are capable, even if reflected, of killing the spores, and (2) that it is really the solar rays which do this directly, and not any effect of a higher temperature, since the gelatine remains solid throughout.

Experience has shown, however, that some precautions are necessary in selecting the anthrax cultures employed for these experiments with gelatine. The light certainly retards or kills (according to its intensity or the length of exposure) virulent spores, but if one takes the spores, mixed with vegetative bacilli, direct from a thoroughly liquefied gelatine culture, or from a bouillon culture, the plates are apt to be liquefied too rapidly for the proper development of the light print, evidently because so much of the liquefying enzyme is carried in when inoculating the plates. The same danger is run when active bacilli alone are employed.

The best method of avoiding these disadvantages has been found to be the following, and it has the additional merit of enabling us to prove, beyond all doubt, that the ripe spores of *Bacillus anthracis* are really inhibited or killed by sunlight.

A few c.c. of sterile distilled water in a tube are thoroughly saturated with the anthrax spores taken from an old culture which has never been exposed to light, and the tube placed for twenty-four hours at 56° C.; this kills all immature spores, bacilli, and enzymes, and leaves us with a crop of the most resistant and fully matured virulent spores.

Experiments with such spores have been made to determine the relative power of the different rays of the spectrum to destroy the anthrax.

It is necessary to note first, however, that in experimenting with the electric light, although but few exposures have been made as yet, it is evident that its effects are feebler than those of the winter sun.

At present it has only been possible to observe that the inhibiting effects are stronger at the blue end of the spectrum than at the red, and exposures to sunlight passing through coloured glasses confirm this result; but the observations are being continued in the hope of getting a perfectly sharp record of the effects of each set of rays.

The following series of experiments are quoted in detail, because they teach several details of importance, in addition to proving the main fact.

On December 7 three gelatine plates and five agar plates were prepared with spores from a very vigorous and virulent agar tube of anthrax. The spores, which were quite mature, were not subjected to heat, but simply shaken in sterile water to wash and separate them thoroughly.

The three gelatine plates were made at 35° C., the agar plates at 60° C., neither of which temperatures could injure the ripe spores.

The three gelatine plates were labelled *p* 1, *p* 2, and *p* 3, and the agar plates *p* 4 to *p* 8 in order.

Immediately after making the plates, all were exposed to the December sun, except plates *p* 4, *p* 5, and *p* 6, and this was done as follows:—In each case the plate had a stencil plate with a cut-out letter on its lower face, and arranged as described above.

p 1, a gelatine plate with a *large* letter M, was exposed, face down, to the light reflected from a mirror (see Fig. 1) for three hours on December 7, and for four hours on December 8, the interval being passed in a cold room (*t* about 8°–9° C.), and then incubated at 20° in the dark.

p 8 was treated in exactly the same manner. But this was an agar plate with a *large* W.

p 2, a gelatine plate with a *large* H, was exposed and heated in the same way, except that no mirror was used, the latter being upwards towards the sun.

p 3, a gelatine plate with a *large* B, was similarly exposed, face up, but a plane mirror arranged to reflect light down upon it.

p 7, an agar plate with a *large* E, was treated exactly as the last.

There now remain the three agar plates, *p* 4, *p* 5, and *p* 6, to account for.

p 4 was placed forthwith in the dark incubator at 20° C.

p 5 and *p* 6 were kept for eighteen hours in a drawer, the average temperature of which is almost 16° C., and were not exposed till next day (December 8), when they lay for five hours, face upwards, and with a mirror above them. *p* 5 had a *small* E, and *p* 6 a broad but small I to let the light in.

After exposure, these also were put in the same incubator with the others.

Nothing was visible to the unaided eye on these plates (except *p* 4) until the 11th instant, though the microscope showed that germination was proceeding on the 10th. The plate *p* 4, however, had a distinct veil of colonies all over it on the 9th, and this had developed to a dense typical growth by the 11th.

On December 11, at 10 a.m., the state of affairs, as regards the exposed plates, was as follows:—

p 5 and *p* 6 showed each a sharp transparent letter—E and I respectively—of clear agar in a dull grey matrix of strong anthrax colonies, which covered all the unexposed parts of the plate.

p 1, *p* 2, and *p* 3 showed in each case a perfectly clear central patch, about 1½ inches diameter, with anthrax colonies in the gelatine around. These anthrax colonies were the *larger and more vigorous the more distant they were from the clear centre.* In other words, the anthrax spores had begun to germinate, and the colonies were growing more vigorously, in centripetal order.

On *p* 7 and *p* 8 germination was beginning, but the colonies were as yet too young to enable one to judge of the results.

The first point of interest is to account for the pronounced results in the plates *p* 5 and *p* 6, and the want of sharp outlines in *p* 1, *p* 2, and *p* 3, and the explanation seems to be that, owing to the plates 5 and 6 having laid over night at 16° C., the spores began slowly to germinate out, *and were consequently in their most tender condition* when exposed to the sunlight next day.

The peculiar centripetal order of development of the colonies on plates *p* 1, *p* 2, and *p* 3 gave rise to the following attempt at explanation. After observing that the clear space in the middle was not due to the centre of the plate being raised, and the infected gelatine having run down to the periphery—a possible event with some batches of Petrie's dishes—it was surmised that the *large* letters employed might give the clue.

This was found to be the case. The solar rays on entering the plate were largely reflected from the glass lid of the plates, and so produced feebler insolation effects on parts of the plate around the letter; these effects were naturally feebler and feebler towards the margin, and so the inhibitory action became less pronounced at distances further and further removed from the centre. Those spores, therefore, which were nearest the periphery germinated out first, and those nearer the centre were retarded and more and more in proportion to their proximity to the insolated letter.

That this is the correct interpretation of the facts follows clearly from the further behaviour of the above plates.

At 10 p.m. on the 11th—*i.e.* twelve hours after the morning examination—the plates *p* 1, *p* 2, and *p* 3 exhibited their respective letters M, H, and B quite clearly, in the grey matrix of anthrax which had rapidly developed in the interval, and excepting a slight want of sharpness in the H of *p* 2, the results could hardly have been more satisfactory.

In *p* 7 and *p* 8 the *very faint* outlines of the letters were also showing.

On the 12th, at 8.30 a.m., the gelatine plates had begun to run, and although the M of *p* 1 was still intact, and very well marked, *p* 2 had liquefied completely, so that the H was a clear patch with blurred outlines in the centre. *p* 3 still showed the outlines of the B, but it was impossible to keep it longer.

The main point was definitely established, however, and the treatment of the plates proves conclusively that the spores are not killed by high or low temperatures, *but by the direct solar rays.*

These experiments are being continued in order to answer some other questions in this connection.

The gelatine and agar after such exposures as have been described are still capable of supporting a growth of *B. anthracis* if fresh spores are sown on them, whence the effects described are not merely due to the sub-strata being spoilt as food material.

Royal Meteorological Society, January 18.—Dr. C. Theodore Williams, President, in the chair.—After the report had been read, and the officers and council for the ensuing year had been elected, the President delivered an address on the high altitudes of Colorado and their climates, which was illustrated by a number of lantern slides.—Dr. Williams first noticed the geography of the plateaux of these regions, culminating step by step in the heights of the rocky mountains, and described the lofty peaks, the great parks, the rugged and grand cañons, and the rolling prairie, dividing them into four classes of elevations between 5000 and 14,500 feet above sea level. He then dwelt on the meteorology of each of these divisions; giving the rainfall and relative humidity, and accounting for its very small percentage by the moisture being condensed on the mountain ranges of the Sierras lying to the west of the Rockies; also noticing the amount of sunshine and of cloudless weather, the maxima and minima temperatures, the wind force, and the barometric pressure. Dr. Williams quoted some striking examples of electrical phenomena witnessed on Pike's Peak (14,147 feet) by the observer of the U.S. Weather Bureau, when during a violent thunderstorm flashes of fire and loud reports, with heavy showers of sleet, surrounded the summit in all directions, and brilliant jets of flame of a rose-white colour jumped from point to point on the electric wire, while the cups of the anemometer, which were revolving rapidly, appeared as one solid ring of fire, from which issued a loud rushing and hissing sound. During another storm the observer was lifted off his feet by the electric fluid, while the wristband of his woollen shirt, as soon as it became damp, formed a fiery ring around his arm. The climate of the Parks is, however, Dr. Williams considered, of more practical interest, and in these magnificent basins of park-like country interspersed with pines, and backed by gigantic mountains, are resorts replete with interest for the artist, the sportsman, the man of science, and the seeker for health. Most of them lie at heights of from 7000 to 9000 feet, and so good is the shelter that usually snow does not long remain on the ground, while Herefordshire cattle in excellent condition are able to fatten on the good herbage, and to lie out all the winter without shed or stable. Dr. Williams predicted for these parks a great future as high altitude sanitaria for the American continent, especially as several of them have been brought within easy distance of Denver, the queen city of the plains, by various lines of railway. The resorts on the foothills and on the prairie plains, at elevations of 5000 to 7000 feet, include, besides Denver, Colorado Springs, Manitou, Boulder, Golden, and other health stations, which can be inhabited all the year round, and where most of the comforts and luxuries of American civilisation are attainable in a climate where not more than half a day a week in winter is clouded over, where the rainfall is only about 14 inches annually, most of which falls during summer thunderstorms, where the sun shines brightly for 330 days each year, and where the air is so transparent that objects twenty miles off appear close at hand, and high peaks are calculated to be visible at a distance of 120 miles. Dr. Williams summed up thus:—The chief features of the climate of Colorado appear to be (1) Diminished barometric pressure, owing to altitude, which, throughout the greater part of the State, does not fall below 5000 feet. (2) Great atmospheric dryness, especially in winter and autumn, as shown by the small rainfall and low percentage of relative humidity. (3) Clearness of atmosphere and absence of fog or cloud. (4) Abundant sunshine all the year round, but especially in winter and autumn. (5) Marked diathermancy of atmosphere, producing an increase in the difference of sun and shade temperatures, varying with the elevation in the proportion of 1° for every rise of 235 feet. (6) Considerable air movement, even in the middle of summer, which promotes evaporation and tempers the solar heat. (7) The presence of a large amount of atmospheric electricity. Thus the climate of this state is dry and sunny, with bracing and energising qualities, permitting outdoor exercise all the year round, the favourable results of which may be seen in the large number of former consumptives whom it has rescued from the life of invalidism and converted into healthy active workers; and its stimulating and exhilarating influence may also be traced in the wonderful enterprise and unceasing labour which the Colorado people have shown in developing the riches, agricultural and mineral, of their country.

Entomological Society, January 18.—Sixtieth Annual Meeting.—Mr. Frederick DuCane Godman, F.R.S., President, in the chair.—An abstract of the treasurer's accounts having been read by Mr. J. Jenner Weir, one of the auditors, the secretary, Mr. H. Goss, read the report of the Council. After the ballot it was announced that the following gentlemen had been elected as officers and Council for 1893:—President, Mr. Henry J. Elwes; Treasurer, Mr. R. McLachlan, F.R.S.; Secretaries, Mr. Herbert Goss and the Rev. Canon Fowler; Librarian, Mr. George C. Champion; and as other members of the Council, Mr. C. G. Barrett, Mr. Charles J. Gahan, Mr. F. DuCane Godman, F.R.S., Mr. Frederic Merrifield, Mr. Osbert Salvin, F.R.S., Dr. David Sharp, F.R.S., Colonel Charles Swinhoe, and Mr. George H. Verrall. The President then delivered an address which, though containing reference to the Society's internal affairs and an allusion to the successful resistance made by naturalists and others to the War Office scheme for establishing a rifle-range in the New Forest, consisted for the most part of full obituary notices of Fellows of the Society who had died during the year, special mention being made of Mr. Henry W. Bates, F.R.S., Prof. Hermann C. C. Burmeister, Dr. Carl A. Döhrn, Mr. H. Berkeley-James, Mr. J. T. Harris, Sir Richard Owen, K.C.B., F.R.S., Mr. Henry T. Stainton, F.R.S., Mr. Howard Vaughan, and Prof. J. O. Westwood, the Hon. Life President. Votes of thanks to the President and other officers of the Society having been proposed by Lord Walsingham, F.R.S., and Dr. D. Sharp, F.R.S., and seconded by Mr. J. H. Leech and Mr. W. H. B. Fletcher, Mr. Godman, Mr. McLachlan, Mr. H. Goss, and Canon Fowler severally replied, and the proceedings terminated.

Linnean Society, January 19.—General Meeting, Prof. Charles Stewart, President, in the chair.—After the confirmation of the minutes the President referred in suitable terms to the losses sustained by biologic science in the deaths of Sir Richard Owen and Prof. J. O. Westwood, who had been Fellows of the Society for 56 and 64 years respectively.—Mr. George Brook showed photographs of corals which he had lately taken and had reproduced by permanent process at a cost below lithography, with the added advantage of permitting amplification by a hand lens.—The President read a paper on the auditory organ of the angel fish (*Rhina squatina*).—Mr. W. Carruthers, F.R.S., V.P.L.S., then laid before the Society the results of a collection made by Mr. Alexander Whyte in the Malanji country, in the Shiré highlands, in October, 1891, and the plants were determined by the officers of the Botanical Department, British Museum, about sixty, or, roughly speaking, one-fifth, proving new to science. Whilst Sir J. D. Hooker defined the flora of Kilimanjaro as Abyssinian in character, the Malanji flora displays a much closer relationship to the Cape.—The last paper was by Mr. G. F. Scott Elliot, and was his report as botanist to the Anglo-French Sierra Leone Boundary Commission, in which he gave an account of the economic aspects of the districts traversed.

Geological Society, January 11.—W. H. Hudleston, F.R.S., President, in the chair.—The following communications were read:—Variolite of the Lleyn, and associated volcanic rocks, by Catherine A. Raisin, B.Sc. Communicated by Prof. T. G. Bonney, F.R.S. The district in which these rocks occur is the south-western part of the Lleyn peninsula, marked on the Geological Survey map as "metamorphosed Cambrian." Some of the holocrystalline rocks are probably later intrusions. The igneous rocks, which are described in detail in the present paper, belong to the class of rather basic andesites or not very basic basalts; they show two extreme types, which were probably formed by differentiation from an originally homogeneous magma. Corresponding to the two types of rock are two forms of variolite. These are fully described, and their mode of development is discussed. The variolites occur near Aberdaron, and at places along the coast. Their spherulitic structure often is developed towards the exterior of contraction-spheriods, and in this and in other particulars they correspond with those of the Fichtelgebirge and of the Durance. The volcanic rocks include lava-flows and fragmental masses, both fine ash and coarse agglomerate. They are associated with limestones, quartzose, and other rocks, which are possibly sedimentary, but which give no trustworthy evidence of the age of the variolites. Prof. Judd complimented the authoress on the evidently great amount of labour and patient research devoted to this investigation. He thought the occurrence of the spherulitic structure round the surfaces of "pillow-like masses," similar to those described by Prof. Dana, was exceedingly interesting, especially when one considered the probably very great antiquity of these Caernarvonshire rocks. He thought, also, the suggestion that early crystallised magnetite-grains had formed the nuclei of the spherulites, was a very interesting and probable one. Mr. Alfred Harker, Profs. Bonney, Hull, and J. F. Blake also spoke.—On the petrography of the island of Capraja, by Hamilton Emmons. Communicated by Sir Archibald Geikie, For. Sec. R.S. The rocks of Capraja consist generally of andesitic outflows resting on andesitic breccias and conglomerates. The southern end seems to have formed a distinct centre of volcanic activity, whose products are younger in age and more basic in character than the rocks of the rest of the island, and may be termed "anamesites." The lavas appear to have flowed from a vent at some distance from the cone, which probably occurred here, and gave out highly scoriaceous fragments. In the other parts of the island andesite is almost everywhere formed, with patches of the underlying breccias here and there in the valley bottoms. The chief centre of activity probably lay west of the centre of the island. Petrographical details of the andesites and anamesites, descriptions of the groundmass and included minerals of each, and chemical analyses are given. As regards the age of the constituents, the author arranges them in the following order, commencing with the oldest:—Magnetite, olivine, augite, mica, felspar, nepheline. After the reading of this paper Dr. Du Riche Preller gave an outline of the leading geological and the analogous petrological features of the several islands of the Tuscan Archipelago, of Corsica, Sardinia, the Carrara mountains, and the Maremma hills. The President also spoke.

Zoological Society, January 17.—Sir W. H. Flower, F.R.S., President, in the chair.—The Secretary read a report on the additions that had been made to the society's menagerie during the month of December, 1892.—Mr. F. C. Selous exhibited and made remarks on the head of a hybrid antelope between the Sassaby (*Bubalis lunata*) and Hartebeest (*B. caama*); also a head of a female Koodoo (*Strepsiceros kudu*) with horns, and heads of some other South African antelopes.—Mr. O. Thomas exhibited some examples (from the Baram River, Sarawak, collected by Mr. Hose) of the monkey that he had lately described as *Semnopithecus cruciger*, and stated that, in spite of the confirmation afforded by these specimens, Mr. Hose thought that this species might possibly be only an erythrism of *S. chrysomelas*.—A communication was read from Mr. E. Y. Watson, entitled, "A proposed classification of the *Hesperiidæ*, with a revision of the Genera." This contained a preliminary classification of the *Hesperiidæ*, including the numerous modern genera, which were arranged under three subfamilies according to the sexual differences, the resting posture, the antennæ, the spurs on the hind tibiæ, and the position of vein 5 (relative to veins 4 and 6) of the fore wing. The subfamilies were named Pyrrhopyginæ, Hesperiinæ, and Pamphilinæ, and the two last were subdivided into sections without names. In all 234 generic names were dealt with, of which 49 were treated as synonyms, while 45 new genera were described. Complete diagnoses were given of all the admitted genera.—A communication was read by Mr. E. E. Austen, entitled "Descriptions of New Species of Dipterous Insects of the Family *Syrphidæ*, in the Collection of the British Museum, with Notes on Species described by the late Francis Walker." This communication contained descriptions of twenty-three new species belonging to the division *Bacchini*, and of one belonging to the *Brachyopini* (genus *Rhingia*). An attempt was made to divide the genus *Baccha*, as at present existing, into three groups, based chiefly upon the shape and markings of the abdomen. The true position of the remarkable genus *Lycastrirhyncha*, founded by Bigot on a species from Brazil, and afterwards cancelled by its author in favour of *Rhingia*, was established. It was shown that this genus had nothing to do with *Rhingia*, but was one of the *Eristalini*, closely allied to *Eristalis*. It was also shown that the genus *Lycastris*, founded by Walker for a species from India, was not identical with *Rhingia* (as had been likewise suggested by Bigot), but belonged to the *Xylotini*, and was allied to *Criorrhina*. A communication was read from Mr. Gilbert C. Bourne, containing descriptions of two new species of Copepodous Crustaceans from Zanzibar, proposed to be called *Canthocamptus finni* and *Cyclops africanus*.—Mr. Sclater exhibited and made remarks on the typical specimen of a rare Argentine bird (*Xenopsaris albinucha*) described by the late Dr. Burmeister in 1868.

Anthropological Institute, January 24.—Anniversary meeting.—Dr. Edward B. Tylor, F.R.S., in the chair.—The following were elected officers and council for the ensuing year:—President, Prof. A. Macalister. Vice-Presidents, J. G. Garson, Chas. H. Read, F. W. Rudler. Secretary, C. Peek. Treasurer, A. L. Lewis. Council: G. M. Atkinson, Henry Balfour, E. W. Brabrooke, Hyde Clarke, J. F. Collingwood, Prof. D. J. Cunningham, W. L. Distant, J. Edge Partington, A. J. Evans, H. Gosselan, Prof. A. C. Haddon, T. V. Holmes, R. Biddulph Martin, R. Munro, F. G. H. Price, Oldfield Thomas, Arthur Thomson, Coutts Trotter, M. J. Walhouse, Gen. Sir C. P. Beauchamp Walker.

EDINBURGH.

Royal Society, January 16.—Prof. Copeland, Vice-President, in the chair.—A paper, by Dr. W. Pole, on the present state of knowledge and opinion in regard to colour blindness, was communicated. He discussed alone the red-green form of colour blindness. In such a case the solar spectrum presents only two hues separated by a nearly colourless portion—a mixture of blue and yellow lights giving rise to a gray colour. According to Young the three primary colour sensations correspond to red, green, and blue or violet, and Maxwell and Helmholtz, reasoning on this theory, conclude that the colours seen in dichromic vision are green and blue. According to Dr. Pole, they are yellow and blue. He asserts that comparisons between normal and abnormal visions show that in general matches of colours made by a normal eye are also matches when regarded by a dichromic eye. He concludes that the two dichromic colours are colours known in normal vision. He then gives reasons for the conclusion that these colours are normal blue and yellow. In answer to the suggestion that the real subjective impressions may differ from what they are supposed to be, he says that the correspondence is proved by a large amount of evidence obtained by comparison with normal phenomena. He thinks that the following conclusions may be drawn from the second edition of Helmholtz's work on optics:—(1) The original mode of explanation of colour blindness by Young's theory is essentially withdrawn as no longer consistent with modern knowledge. The universal concurrent testimony, that the ordinary colour dichromic vision generally corresponds with is normal yellow and blue and white, is no longer disputed, and although there are variations of sensations in regard to red and green, the old ideas of blindness to red and green as separate and contrasting defects are abandoned; (2) that Young's general theory of three fundamental colour-sensations is still adhered to, but that the colours are now believed to differ considerably in the spectrum; (3) that dichromic vision might exist consistently with the retention of three fundamentals; (4) that the most prevalent form of dichromatism might be explained by the junction of the red and green fundamentals forming yellow. In conclusion, he regretted that the colour-vision committee of the Royal Society, in a recent chart dealing with colour blindness, had adhered to the old view held by Clerk Maxwell. Sir George Stokes remarked that the fundamental part of Young's original theory was that there were three colour sensations; and though he supposed them to be red, green, and violet, that was not essential. Maxwell only chose red, green, and blue, as representative sensations. He was doubtful of the wisdom of publishing the charts alluded to lest it might lead to misconception. The object of publishing them was to give to the public a general idea of the conclusions derivable from the trichromic theory.

SYDNEY.

Royal Society of New South Wales, December 7, 1892.—Prof. Warren, President, in the chair.—The Chairman announced that the Clarke Medal for 1893 had been awarded by the Council to Prof. Ralph Tate, of the Adelaide University.—A letter was read from the Hon. Ralph Abercromby, enclosing a cheque for £100, which he desired to place in the hands of the Council of the Society with the object of bringing about an exhaustive study of certain features of the Australian weather, the particulars to be furnished in a later letter. The following papers were read:—Observations on shell heaps and shell beds, the significance and importance of the record they afford, by E. J. Statham.—A new mineral from Broken Hill, by C. W. Marsh (communicated by Prof. Liversidge).—Notes on some Australian stone weapons, by Prof. Liversidge, F.R.S.—Notes on the recent cholera epidemic in Germany, by Dr. Schwarzbach.—Results of observations of Wolf's comet II., 1891, Swift's comet I., 1892, and Winnecke's periodical comet, 1892, at Windsor, New South Wales, by John Tebbutt.—On the comet in the constellation Andromeda, by John Tebbutt.—Languages of Oceania, by Dr. John Fraser.

August 17.—*Engineering Section*.—C. W. Darley in the chair.—Papers read:—Various systems of tramway traction, by W. F. How.——November 16.—Some notes on the economical use of steam, by T. H. Houghton.—Recent bridge building in New Zealand, by A. Alabaster.

PARIS.

Academy of Sciences, January 23.—M. Lœwy in the chair.—Note on Nicolas de Kokcharow, by M. Daubrée.—Contributions to the study of the function of camphoric acid, by M. A. Haller.—On the pepto-saccharifiant action of the blood and the organs, by M. R. Lépine. If blood is poured into several parts of water at 56° C. a considerable quantity of sugar is formed in a few seconds, and the formation goes on for about an hour with decreasing rapidity. In cold or lukewarm water sugar is also produced, but its production is for the most part compensated by simultaneous glycolysis. It is also probable that the production of sugar is preceded by that of peptone. If an organ which does not enclose glycogen in any perceptible quantity be macerated for about an hour in three or four parts of water, the aqueous extract only contains a very small quantity of substances capable of reducing Fehling's solution, and hardly any sugar. If to this aqueous extract be added a small quantity of peptone, and the whole be kept at 56°C. during an hour, a certain quantity of sugar is formed, as proved by fermentation and the phenylhydrazine test. Hence the aqueous or glycerine extract contains a ferment which may be termed pepto-saccharifiant. It is probable that the formation of sugar is not confined to the liver, as ordinarily supposed, but that several organs play a part in it.—Observations of the planet Charlois T (December 11, 1892), made at the Toulouse Observatory, by M. B. Baillaud.—Contribution to the investigation of the solar corona apart from total eclipses, by M. H. Deslandres (see Astronomical Column).—Observations of the sun made at the Lyon Observatory (Brunner equatorial) during the latter half of 1892, by M. Guillaume.—On the limitation of degree for the general algebraic integral of the differential equation of the first order, by M. Autonne.—On Van der Waals's equation and the demonstration of the theorem of the corresponding states, by M. G. Meslin.—Magnetic properties of bodies at different temperatures, by M. P. Curie.—The magnetic permeabilities of a series of diamagnetic bodies, including, amongst others, bismuth, antimony, phosphorus, sulphur, and some potassium salts, were determined by enclosing them in an exhausted glass vessel exposed to a magnetic field, and subsequently repeating the experiment with the glass alone. Most of the substances showed a remarkably constant coefficient. Water and quartz did not show a perceptible variation with temperature, and potassium nitrate had the same coefficient when solid and when fused. That of bismuth, on the other hand, fell steadily up to the point of fusion, and then (at 273° C.) abruptly from 0·957 to 0·038, after which it remained constant. Electrolytic antimony had a much feebler coefficient than the ordinary variety.—Contribution to the study of equalisers of potential acting by flow, by M. G. Gouré de Villemontée.—Luminous phenomena observed at the Lyon Observatory on the evening of January 6, 1893, by M. Gonnessiat.—A method for measuring objectively the spherical aberration of the living eye, by M. C. J. A. Leroy.—On the atomic weight of palladium, by MM. A. Joly and E. Leidié.—Action of the alkaline alcoholates on camphoric and other anhydrides, by M. P. Cazeneuve.—Modification of arterial pressure under the influence of pyocyanic poisons, by MM. Charrin and Teissier.—On some cases of infectious arthrodentary gingivitis observed in animals, by M. V. Galippe.—Primary bedding of platinum in the Ural, by M. A. Inostranzeff. The native platinum occurs embedded in a rocky matrix consisting of the variety of peridotite known as dunite. It is found in Mount Solovieff, which consists of alternate layers of chrome-iron and serpentine.—On the existence of overfolds in the Blida Atlas (Algeria), by M. E. Ficheur.

BERLIN.

Physical Society, January 6.—Prof. du Bois Reymond, President, in the chair.—Prof. Raoul Pictet gave an account of experiments made by Messrs. Sarasin and De la Rive by which the rate of the electric waves discovered by Hertz had been measured, and their identity with waves of light in the ether determined. By using large metallic surfaces sixteen metres in diameter as reflectors, and by allowing the discharge of the primary spark to take place under oil instead of in the air, it was found possible to obtain stationary electric waves in a long gallery and to determine their nodal points. In the discussion which ensued Prof. Kundt stated that Dr. Zenker was the first person who had explained the photographing of colours by means of stationary waves; that stationary light-waves were first experimentally determined by Dr. Wiener, and that Seebeck was the first to take photographs of coloured objects. After Prof. H. W. Vogel, pictures due to the action of light were first taken by a doctor named Schulz, in Halle. In 1727 this observer treated a solution of nitrate of silver in a small box with calcium chloride and obtained a greyish precipitate. He then covered the box with a lid in which was a hole the shape of some letter, and on subsequently examining the precipitate he saw a dark image of the letter on it. The experiment was found to fail in the dark. Schulz hence concluded that the image of the letter was due to the action of light.

Meteorological Society, January 10.—Prof. Schwalbe, President, in the chair.—Dr. Kremser spoke on the imperfection of the means available for the study of atmospheric currents, which, even in the most elevated stations, are profoundly modified by the topography of the neighbourhood. The direction and rate of these currents can only be ascertained by observing the motion of a small pilot-balloon of some one cubic metre capacity, a specially constructed theodolite being used for this purpose.—Prof. Hellmann exhibited a series of photographs of snow-crystals taken by Dr. Neuhauss, together with the oldest existing figures of these crystals, due to Olaus Magnus in 1455. The chief points of interest shown by these photographs were the not infrequent asymmetry of the crystals and the occurrence on them of small ice-lumps.

Physiological Society, January 13.—Prof. du Bois Reymond, President, in the chair. Dr. Behring gave an account of the present state of affairs as regards what may be called the blood-serum therapeutists, illustrating his remarks by experiments he had made with serum from an immune horse on mice inoculated with tetanus-bacilli. A number of mice were inoculated with more or less strong doses of the bacilli. Those which had previously been treated with the horse-serum did not die, and in many cases where the serum was injected after the inoculation death did not ensue. Observations on man are in progress, and will be published as soon as sufficient data are to hand on the treatment of tetanus and diphtheria by the use of serum from immune animals.—Dr. Hahn, of St. Petersburg, gave an account of experiments made in conjunction with Profs. Pawlow and Nencki on the action of an Eck's fistula, and the conducting of blood from the portal vein directly into the inferior vena cava. Among the various results of the operation he stated that the output of urea was lessened and that of uric acid increased, a result which the experimenters attributed to a cessation in the conversion of carbamic acid into urea due to exclusion of the liver. They further found that carbamic acid produced symptoms similar to those exhibited by the animals on which they had operated.—Prof. Kossel and Dr. Raps exhibited an automatic mercurial pump for blood-gas analysis.

THURSDAY, FEBRUARY 9, 1893.

THE MILKY WAY.

The Milky Way from the North Pole to 10° of South Declination, drawn at the Earl of Rosse's Observatory at Birr Castle. By Otto Boeddicker. (London: Longmans, Green, and Co., 1892.)

DR. OTTO BOEDDICKER devoted the clear moonless nights for five years, from October 1884 to October 1889, to delineating the Milky Way as it appeared to his unaided eyes at Parsonstown, Ireland. His drawings were deposited in the library of the Royal Astronomical Society, and a note accompanying them was read at the meeting of the Society in November 1889. The work now before us consists of four excellent lithographic reproductions of these drawings, a brief introductory preface being added by Dr. Boeddicker.

The working maps for the drawings were taken from Argelander's "Uranometria Nova," the Milky Way being inserted by means of stump and lead pencil. This medium was found very unsuitable for photographic reproduction, and in preparing the lithographic stones for these charts photography was used for the stars, and the Milky Way was introduced by hand work. Mr. W. H. Wesley, the Assistant Secretary of the Royal Astronomical Society, is responsible for this latter portion of the work, and the results are a splendid testimony to his care and skill. Dr. Boeddicker is to be congratulated upon having secured the services of so excellent an artist.

Plate I. is a detailed drawing of the Section Cygnus-Scutum, Plate II. of the Section Cassiopeiæ, and Plate III. of the Section Aurigæ-Gemini-Monocerotis. In these plates an attempt has been made to represent accurately the appearance of the galaxy, all the differences of luminosity being represented as they actually appeared to Dr. Boeddicker. In Plate IV. a general view on a smaller scale of the whole Milky Way from the North Pole to 10° south declination is given, the contrast being deliberately exaggerated in order to bring out clearly all the details.

The area of the Milky Way indicated on these drawings is very much greater than that on any previously published representations, while for delicate details and faithful reproduction of contrast the plates are unapproached. In many respects Dr. Boeddicker's drawings are a new revelation, branches, wisps, and feelers being shown extending from the main body so as to include stars, clusters and nebulæ, and even whole constellations not previously recognized as connected with or forming part of the Milky Way. Polaris, γ Arietis, Prœsepe, the Pleiades, the Hyades, the great nebula in Andromeda, and nearly the whole of the constellation Orion, are thus joined to the galactic circle. Numerous bright patches, channels, rifts, and interlacing lines of luminous matter hitherto unsuspected are revealed by Dr. Boeddicker's long and patient work, and exponents of disc, spiral, and other theories as to the construction of the Milky Way will find considerable difficulty in accounting for the details shown.

It is very difficult to compare drawings of the Milky Way made by different observers without optical aid. There are such wide variations in unaided vision, so many peculiarities introduced by long and short sight, by astigmatism, by irradiation in the retina, and by other physical and physiological imperfections, that it may safely be asserted that no two persons get exactly the same naked-eye impression of such a vague object as the Milky Way. As no details are given about Dr. Boeddicker's eyes we are probably justified in inferring that they are practically normal, but we doubt whether any other observer, even with special training, could check or correct these charts with reasonable prospect of convincing the original artist of error in the representation of the Milky Way as it appeared to him. Individual peculiarities of sight are minimized by the use of slight optical aid, and two equally experienced observers would be more likely to agree in their delineations of the Milky Way if they used similar telescopes, of say 1-inch aperture, or even ordinary opera glasses. Dr. Boeddicker's appeal to other observers to "verify and correct" his work will probably bring him plenty of correspondence, but can scarcely lead to any important correction in his magnificent drawings.

Dr. Boeddicker considers that "the first step necessary towards the knowledge of the sidereal universe is a thorough acquaintance with the Milky Way as it appears to the naked eye," and hopes that by comparison and the superposition of naked-eye drawings on photographs "some knowledge of the structure of the Milky Way *in the line of sight* may be obtained." This idea is founded on the theory that there is a direct connection between the magnitudes of stars and their distances. Littrow's analysis of Argelander's catalogue of stars certainly seemed to justify belief in this connection, but recent work has entirely disproved the hypothesis. Measurements of the parallax of stars indubitably prove that some faint stars are near, while some of the brightest are at such distances as to have no appreciable parallax. Thus α Orionis, α Virginis, α Leonis, and α Cygni have no parallax, while the 5th magnitude star 61 Cygni has a parallax of between 0″·4 and 0″·5. Photographs of the Pleiades show that we have in that cluster stars differing by as much as 13 magnitudes at approximately the same distance from us. Russell's photograph of α Crucis plainly indicates a direct physical connection between that star and many stars of the 14th and 15th magnitudes which should, according to the theory, be nearly 1000 times more distant. Streaks of nebulæ connect α Cygni and γ Cygni with long lines and stars of about the 16th magnitude in Dr. Max Wolf's photographs of the Milky Way. From considerations of parallax observations of stars and from examination of photographs we are forced to conclude that there is no real connection between magnitude and distance, and that the differences of magnitude of stars are due to differences of size and physical condition. Stars differ enormously in light-giving power, and the actual light emitted by α Cygni must be nearly a million times greater than that from the faint stars directly connected with it and at practically the same distance from us. There is therefore very little chance of adding to our knowledge of the Milky Way "in the line of sight" by superposition of naked-eye drawings on photographs.

In his preface Dr. Boeddicker frequently speaks of "nebulosity," "nebulous light," and "nebulous matter," when he means luminosity and luminous matter. In ante-spectroscopic days the terms nebula and cluster were used almost indiscriminately, a nebula being looked upon as simply an irresolvable cluster, and this error still survives in many astronomical text-books and compilations, but Dr. Boeddicker should have avoided it. When we consider that the majority of the stars in the cluster which we call the Milky Way are of the Sirian type, we see how misleading is the use of the terms nebulous light and nebulous matter. A. T.

THE THEORY OF SUBSTITUTIONS AND ITS APPLICATIONS TO ALGEBRA.

The Theory of Substitutions and its Applications to Algebra. By Dr. Eugen Netto. Translated by F. N. Cole, Ph.D. (Mich.: Ann Arbor, 1892.)

THE theory of substitutions abstractly considered is concerned with the enumeration and classification of the permutations of a set of n different letters $x_1, x_2, \ldots, x_n$. It is scarcely apparent at first sight that a far-reaching mathematical theory could be built on a basis so simple, still less that there should be any connection between this and the complicated question of the solution of algebraical equations by means of radicals. It may be worth while, in order to excite the interest of mathematical readers in the work before us, to mention one or two points in the Theory of Substitutions which will give an inkling of the nature of its connection with the interesting problem just mentioned.

The operation of replacing—say in any function $\phi(x_1, x_2, x_3)$—any permutation of the letters, say x_1, x_2, x_3, by any other, say x_1, x_3, x_2, is called a *substitution*. This operation is denoted explicitly by $\begin{pmatrix} x_1, x_2, x_3 \\ x_1, x_3, x_2 \end{pmatrix}$, or shortly by a single letter s. Thus $s\phi(x_1, x_2, x_3) = \phi(x_1, x_3, x_2)$; and again: If t denote the substitution $\begin{pmatrix} x_1, x_2, x_3 \\ x_3, x_2, x_1 \end{pmatrix}$, $t\phi(x_1, x_3, x_2) = \phi(x_3, x_1, x_2)$. We may indicate the successive application of the two substitutions s and t by multiplying the symbols st in the order of application: thus $st\phi(x_1, x_2, x_3) = \phi(x_3, x_1, x_2)$ and $ts\phi(x_1, x_2, x_3) = \phi(x_2, x_3, x_1)$. In particular, the repetition of the same substitution may be represented by powers of the symbol; thus $s^2\phi(x_1, x_2, x_3) = \phi(x_1, x_2, x_3)$. The identical substitution $\begin{pmatrix} x_1, x_2, x_3 \\ x_1, x_2, x_3 \end{pmatrix}$ is represented by unity. The total number of different substitutions of n letters is obviously $n!$; consequently, if we form the consecutive powers of any substitution we shall ultimately arrive at a power s^m which will be the identical substitution, m being some positive integer not exceeding $n!$: m is called the *order* and n the degree of the substitution.

If among the substitutions of any given degree we can select a set which have the property that the product of any two furnishes another substitution belonging to the set, we obtain what is called a *group of substitutions*. The whole of the $n!$ substitutions of n letters obviously form a group, and the identical substitution by itself forms a group. It is easy, however, to see that in general there are other groups among the substitutions of a given degree. Consider, for example, any rational function $\phi(x_1, x_2, \ldots, x_n)$ which is not wholly asymmetric: there must exist a set of substitutions each of which leaves the value of ϕ unaltered. A substitution which is the product of any number of these must also leave ϕ unaltered: hence the set in question forms a group. We have here a fundamental point in the theory of substitutions, viz., the existence of a group of substitutions and the correlation therewith of rational functions which are unaltered by all the substitutions of the group. The group is said to belong to all the functions which it leaves unaltered; and these functions are said to form a family which is characterized by the group. Thus the group of a wholly asymmetric function is the identical group consisting of the substitution ^{1}; the group of the wholly symmetric functions consists of the whole of the $n!$ substitutions of the n^{th} degree; the group of the alternating functions consists of all those substitutions which are equivalent to an even number of transpositions, and so on. It is obvious that every rational function determines a group of substitutions, and it may be shown that, conversely, for every group of substitutions we may construct an infinity of rational functions which are unaltered by the substitutions of the group. The significance of this correlation between a group and a family of functions depends on the following important theorem, which is due in substance to Lagrange. If ψ be a rational function which is unaltered by all the substitutions of the group of ϕ (in other words, if the group of ψ contain the group of ϕ) then ψ can be expressed as a rational function of ϕ, and the n elementary symmetric functions

$$C_1 = \Sigma x_1,\ C_2 = \Sigma x_1 x_2, \ldots, C_n = x_1 x_2 \ldots x_n.$$

A particular case of this is the theorem that if the groups of ψ and ϕ be identical, then each can be expressed as a rational function of the other, and of the elementary symmetric functions. A limiting case of this theorem is the familiar result that every rational symmetric function can be expressed as a rational function of the elementary symmetric functions. As a special example consider the the two wholly asymmetric functions $\psi = ax_1 + bx_2$, $\phi = a/x_1 + b/x_2$: these both belong to the identical group, since they are changed by every substitution of the letters x_1, x_2. Hence ψ can be rationally expressed as a function of ϕ, C_1, C_2. The actual expression is in fact

$$\psi = \{2(a-b)^2C_2 - (a^2+b^2)C_1^2 + (a+b)C_1C_2\phi\}\{-(a+b)C_1 + 2C_2\phi\}/(a-b)^2(C_1^2 - 4C_2).$$

The application of the theory of substitutions is limited in the first instance to rational functions. Its use in the theory of the solution of algebraical equations by means of radicals is based on the following important result in the theory of irrational functions. Any root of a solvable equation $f(x) = 0$ can be expressed as a rational integral function of certain elements $V_1, V_2, \ldots, V_1$, the coefficients of which are rational functions of the coefficients of $f(x)$ and of primitive roots of unity. The quantities $V_1, V_2, \ldots, V_n$ are on the one hand rational integral functions of the roots of $f(x) = 0$ and of primitive roots of unity, and on the other hand are determined by a series of equations

$$V_a p_a = F_a(V_{a-1}, V_{a-2}, \ldots, V_v),$$

where p_a is a prime number and F is a rational function of the $V - s$. For example, in the case of the cubic

$x^3 - C_1x^2 + C_2x - C_3 = 0$, if $\Delta = -27C_3^2 + 18C_1C_2C_3 - 4C_1^3C_3 - 4C_2^3 + C_1^2C_2^2$, $S = 2C_1^3 - 9C_1C_2 + 27C_3$, $T = 9C_3 - 3C_1C_2$, the relations in question are

$$V_3^2 = -27\Delta,\ V_2^3 = \tfrac{1}{2}(S + V_3),\ V_1^3 = \tfrac{1}{2}(S - V_3);$$
$$V_1 = x_1 + \omega^2x_2 + \omega x_3,\ V_2 = x_1 + \omega x_2 + \omega^2x_3,$$
$$V_3 = T + 3\omega(x_1^2x_3 + x_2^2x_1 + x_3^2x_2) + 3\omega^2(x_1^2x_2 + x_2^2x_3 + x_3^2x_1);$$
$$x_1 = \tfrac{1}{3}\{C_1 + V_1 + V_2\},\ x_2 = \tfrac{1}{3}\{C_1 + \omega V_1 + \omega^2V_2\},$$
$$x_3 = \tfrac{1}{3}\{C_1 + \omega^2V_1 + \omega V_2\}.$$

By means of this theorem and certain elementary principles of the theory of substitutions an elegant and simple demonstration can be given of Abel's theorem that the solution by radicals of the general equation of the n^{th} degree is impossible when $n > 4$: see § 217 of the work before us.

Although the theory of substitutions bears, as we have just shown, on some of the oldest and most interesting of the problems of algebra, it has been comparatively little studied, especially by English speaking mathematicians. Dr. Cole has therefore rendered us a service of great importance by translating one of the standard treatises on this subject. Of the three that were at his disposal we think that he has chosen the one most likely to be useful to a beginner. While Serret in his "Higher Algebra" and Jordan in his "Traité" treat the theory from an abstract and more general point of view, Dr. Netto constantly associates with the substitution the function on which it is supposed to operate. This gives a powerful concrete aid to the comprehension of the propositions of the abstract theory and also helps the student to grasp their application. The great danger in subjects of such generality is that the stream of theorems is apt to run off the mind of the learner without soaking in, like water off the proverbial duck's back.

Dr. Netto's book will be found to contain all the ordinary theorems regarding the classification of substitutions, *e.g.* the existence of groups, transitive and intransitive, primitive and non-primitive, simple and compound; the theory of the algebraic relations between the values of multiple-valued functions and between functions belonging to or included in the same family; and also a considerable number of theorems regarding special groups. The applications embrace the theory of resolvents in general and of the Galois resolvent in particular; the general theory of the solvability of equations by means of radicals; the theory of the group of an equation and a discussion of the criteria of solvability; besides special applications to the cyclotomic and Abelian equations, and to equations three roots of which are connected by a rational relation.

The translation has been admirably done, both from the linguistic and from the mathematical point of view. We found, it is true, here and there passages which were somewhat obscure; but in every case, on comparing with the original, we found the rendering to be absolutely faithful. Such obscurities therefore must be charged either to the author, or to the nature of the subject, or to the idiosyncrasy of the critic, and not to the translator. We congratulate Mr. Cole on the successful completion of his arduous task, and heartily recommend the result to every lover of the most ancient and the most beautiful of all the sciences. G. CH.

THE BRAIN IN MUDFISHES.

Das Centralnervensystem von Protopterus annectens; *eine vergleichend Anatomische Studie.* Von Dr. Rudolf Burckhardt. (Berlin: R. Friedländer und Sohn, 1892.)

THE Mudfishes, Dipnoi, from many peculiarities in their structure, have attracted the especial attention of anatomists and zoologists. Important monographs on Lepidosiren have been written by Owen and Wiedersheim, whilst Huxley, Günther, and Beauregard have described the anatomy of Ceratodus. Serres, in 1863, made a contribution to the anatomy of the nervous system of Protopterus, Fulliquet in 1886, and Parker in 1888, have also added to our knowledge of its structure; and now Dr. Burckhardt has published a well-illustrated monograph on the central nervous system of *Protopterus annectens.* He had obtained an ample supply of this fish from Herr W. Jezler, a merchant whose business engagements had taken him to the neighbourhood of Bathurst, Senegambia. On more than one occasion Dr. Burckhardt had received living fish, so that he was able to study the microscopic anatomy by the use of the most recent technical methods, and has thus added materially to our knowledge of the brain of this animal.

The author found, in the anterior horn of grey matter of the spinal cord, remarkably large nerve-cells, which possessed both branching protoplasm processes and an axial-cylinder process. In the lateral and posterior horns nerve-cells somewhat smaller in size were seen. The medulla oblongata gave origin to nerves which he names hypoglossal, vagus, glosso-pharyngeal, acusticofacialis, and trigeminus. He also describes two slender nerves as abducens and trochlearis, so that the Dipnoi are not, as some have said, destitute of these nerves. The cerebellum formed the anterior boundary of the 4th ventricle. Large nerve-cells, corresponding to those of Purkinje in the mammalian brain, were not seen. The mid-brain was distinct, and gave origin to a root of the trigeminus, to the optic tract and to the oculo-motor nerve: grey matter containing nerve-cells was grouped around the aqueduct of Sylvius.

Whilst Protopterus corresponded closely with the lowest vetebrates in the regions of the mid and hind brains it presented striking peculiarities in the pineal region. The roof of the 3rd ventricle was complicated, and possessed a velum, which represented a middle choroid plexus; a conarium, and a structure like that which Edinger has named "Zirbelpolster." The epiphysis (*Zirbel*) was attached to the skull by the arachnoid membrane.

The fore brain was well developed, and divided into two hemispheres. He recognized in it a posterior ventral swelling, which, because it contained cells similar to those found in the dentate gyrus (*fascia dentata*) of the higher brains, he describes as a lobus hippocampi. He distinguished a fissure which separated the lobus olfactorius from the pallial part of the hemisphere, so that he harmonizes the fore brain in its fundamental divisions with the mammalian brain as described by Broca and Turner. He directs attention to an elevation ventrad of the lobus olfactorius, which he calls the lobus post-olfactorius. This lobe is also found in the brains of

Selachia and Amphibia, and apparently corresponds to the lobus olfactorius posterior described by His in the human embryo, which forms the anterior perforated spot in the adult human brain. As regards its structure the hemisphere possessed central grey matter containing nerve-cells which lay around the hemisphere ventricle; also a mass of grey matter which he calls corpus striatum; whilst in the more posterior part of the ventral region of the hemisphere were nerve-cells which represented a cortical layer. In the dorsal region of the hemisphere also cortical nerve-cells were found, which were arranged as an inner and an outer layer. The cells of the cortex gave origin to nerve fibres. A definite anterior commissure was present, the fibres of which passed on each side into the lobus hippocampi. Burckhardt, also, figures, as distinct from the anterior commissure, fibres which he regards as the corpus callosum of Osborn. The most important tract of nerve fibres was the basal bundle, which ascended from the spinal cord into the corpus striatum.

One of the most interesting chapters in Burckhardt's memoir is that in which he gives an account of the saccus endolymphaticus. Wiedersheim had described in 1876, in *Phyllodactylus europæus*, a sac with many branching diverticula, filled with otolith-sand and lying in relation to the choroid plexus of the 4th ventricle. Hasse had previously seen in Amphibia a similar structure which Coggi had investigated in the frog. Burckhardt has for the first time observed and figured it in Protopterus. The saccus communicated by a narrow neck with the sacculus and utriculus of the auditory vesicle, and with its diverticula overlaid the region of the 4th ventricle, and extended as far back as the 1st pair of spinal nerves.

The memoir contains a short chapter on the phyletic development of the brain of Protopterus. Starting with Selachia, he considers that one line of development has been through Protopterus to Ichthyophis, and thence to the Urodela and Anura; another through Ceratodus to Reptilia and Mammalia; whilst a third line is from the Selachia to the Ganoids and Bony Fishes.

OUR BOOK SHELF.

The Chemical Basis of the Animal Body. An Appendix to Foster's "Text-Book of Physiology" (fifth edition). By A. Sheridan Lea, M.A., D.Sc., F.R.S. (London: Macmillan and Co., 1892.)

LIKE its parent volume, this well-known appendix has grown in bulk considerably, so that it now constitutes a treatise (separately paged and indexed) on the chemical substances occurring in the body. It contains numerous references to the text of Foster's "Physiology," and so the two may be most profitably read together.

The plan pursued in the present edition is the same as in former editions; the chemistry of the body is described under the headings of the names of the chemical substances. This plan has its advantages. It for instance gives a completeness to the description of any particular substance, whereas the other plan of describing the facts of animal chemistry, under the headings of the tissues, organs, and functions involves a certain amount of repetition and the facts relating to any one group, such as the proteids and carbohydrates will be found distributed in different chapters. Dr. Sheridan Lea's plan has, however, the disadvantage that it destroys continuity. Many of the paragraphs are necessarily short, and one passes from one subject to another with a certain amount of abruptness. The style of the writing is, however, interesting and clear, so that this disadvantage is reduced to a minimum. The parts that treat the subject in a fuller style, such as those in which ferment action, the origin of urea in the economy, or the relation of hæmoglobin to bile pigment are discussed, are models of lucid writing.

The book opens with a description of the proteids and ferments, the most important of physiological substances, but those of which, from the chemical standpoint, we know least. The simpler materials found in the body or its excreta are treated next. This is the more chemical part of the book, and the author expresses his indebtedness to Dr. S. Ruhemann for assistance here. One doubts whether this part of the work will prove attractive to ordinary students. There is no question that all medical students should be educated up to it, but at present organic chemistry and structural formulæ are subjects they are inclined to fight shy of. The concluding chapters are again devoted to substances of which we have a physiological rather than a chemical knowledge, namely, the pigments.

The figures of crystals, which form a new feature in the present edition, have been taken from the works of Krukenberg, Kühne, and Funke. One cannot conclude this notice without alluding to the extensive references to literature that are given throughout. This will prove a most valuable assistance to all original workers, and to those more earnest students who desire to go deeper into the subject. The references are provided with a separate index. They are chiefly to German literature. The German leanings of the author are seen also in the spelling of sarkosin, kreatin, &c. The final *e* is always omitted in the names of the amido acids. It would be a good thing in the future if international uniformity in the names of chemical compounds were adopted. In the meantime it seems a pity that Dr. Lea has not seen fit to use the spellings recommended by the Chemical Society of London.

The author is to be congratulated on having brought his labours to a successful conclusion, and we can pay the present volume no better compliment than to say that it is well worthy of those that have preceded it.

W. D. H.

Chambers's Encyclopædia. New Edition. Vol. X. (London and Edinburgh: W. and R. Chambers, 1892.)

THE editor and publishers of the present work may be cordially congratulated on the fact that it has now been successfully completed. A better encyclopædia of like scope does not exist in our own or any other language. Nominally it is merely a new edition; but in reality, as the editor claims in the preface, it must be regarded as to all intents and purposes a new work. One of the chief difficulties in an undertaking of this kind is to secure that each subject shall have the degree of attention which properly belongs to it, no single subject or group of subjects being permitted to usurp space which ought to be otherwise occupied. The editor has grappled with this difficulty so effectually that few readers will have occasion to complain of any lack of proportion in the length of the various articles. Another striking merit of the work is that all important subjects have been entrusted to specialists, so that students may have full confidence in the accuracy of the information offered to them about matters in which they happen to be particularly interested. The space at the disposal of the writers was so limited that what they have to say is not, of course, exhaustive, but it is sound as far as it goes, and is generally presented with most praiseworthy simplicity and clearness. The present volume falls in no respect below the level of those which have preceded it. Among the writers of scientific articles are Prof. James Geikie, who deals with the triassic system and with volcanoes; Prof. Knott, who expounds the principles of thermodynamics; Dr. R. W. Philip, who writes of tubercle; and Sir F. Bramwell, who has a paper on water-supply.

Arthur Young's Tour in Ireland (1776–79). Edited, with Introduction and Notes, by A. W. Hutton. Two vols. (London: G. Bell and Sons, 1892.)

THIS reprint will be of real service to all who study the evolution of economic conditions in Ireland, and much of it ought also to excite and maintain the interest of the general reader. Arthur Young, as every one knows, was a remarkably accurate observer of such things as travellers have opportunities of noting, and his book on Ireland is in its own way hardly less valuable than his more celebrated work on France. The work was first published in 1780, in the course of which two English editions and one Irish edition were issued. Since that time it has not until now been reprinted as a whole. Mr. Hutton has done his work as editor admirably, and a most useful bibliography has been prepared by Mr. J. P. Anderson.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Some Lake Basins in France.

A FEW weeks since M. Delabecque, Ingénieur des Ponts et Chaussées at Thonon, kindly presented me with a copy of a work issued under his superintendence and to a great extent executed by himself,[1] to which I should be glad to call the attention of students of physiography. M. Delabecque, commissioned by the French Government, has made a series of soundings of ten lakes in France, near the Alpine region, and this Atlas records the results of his work. Contour-lines, in most cases 5 metres apart, indicate the forms of the lake-basins; the use of varying tints in blue makes these more distinct. Chief among the lakes included is the Léman, in the survey of which, as only one shore is French territory, the Swiss engineers have cooperated. A copy of this on a reduced scale, and without colours, appeared in Prof. Forel's book, "Le Lac Léman" (see NATURE, Nov. 3, 1892). Next in importance come the lakes of Annecy and of Bourget; the remainder are situated either in the French Jura or on the margin of the outer limestone zone of the Alps, a little south of the Rhone.

Excluding the Lake of Geneva, which was noticed in the article just mentioned, these lakes are especially interesting for their bearing on the difficult problem of the origin of lake-basins. Except the Lac de Bourget, none of these can be said to lie in a great mountain valley, or on the probable track of a great glacier. If then their basins have been excavated by glaciers, we might fairly expect the Alps and Jura to be "spattered" with lakes, for no appeal can be made to exceptional circumstances: while if the contours of their beds present resemblances to those of the larger Alpine lakes, such as the Lake of Geneva, the same explanation ought to apply in the main to both groups.

Without a reproduction of the charts it is impossible to give more than a rough idea of the evidence which they afford, but the following statements may be helpful. As a general rule the lakes deepen as they broaden, the deepest water being commonly found in the widest part. If in the course of the lake the shores markedly approach so as to form a kind of "narrow," this corresponds with a submerged neck or "col," which separates the bed into two basins, rising perhaps 10 metres or more above their general level. Not seldom the bed of a lake consists of a linear series, three to six in number, of shallow basins, so that a contour line, drawn along the axis of the lake, undulates up and down with an "amplitude" of from perhaps 3 to 5 metres. A rather long, blunt-ended oval is the prevalent form of these lakes, but to this there are exceptions. So far as can be ascertained the contours of the land above the water-line are reproduced beneath it. For instance, under the steep slopes of the Mont du Chat the bed of the Lac de Bourget plunges abruptly down to a depth of over 120 m. (its greatest depth being about 145 m.).

Of the Jura lakes, the Lac de St. Point (848·95 m. above the sea) is rather more than 6 kilometres long, the general width being rather less than one-tenth of this; a considerable part of its floor is 30 to 35 metres deep, and its greatest depth is about 42 metres. It contains no less than 6 basins, parted by "cols" about half-a-dozen metres above their lowest parts. This lake is on the course of the Doubs, and lies parallel with the general strike of the Jura, *i.e.* from N.E. to S.W. The Lac de Brenets on the same river, nearly 100 metres lower down, is a narrow, winding lake, roughly 150 metres wide and perhaps 8 or 9 times as long. At its upper end is a sharply projecting, rather shallow bay, but the channel of the Doubs can be traced clearly through this, deepening gradually from 5 to nearly 27 metres and the whole lake is evidently only an enlargement of the river.

The subalpine lakes are no less interesting, and their testimony generally agrees with that summarised above. Want of space forbids us to mention more than the lake of Annecy. This is deepest (about 65 m.) in its northern and widest part (nearest to the effluent). The sub-aqueous contours on the western side are interrupted, to within about 10 metres from the bottom of the lake, by a prominence, just like a drowned hilly spur. The shallowest soundings over this, near its northern (outer) part, are only 3·3 metres, and the ground falls rapidly down from 5 to 55 metres. On its northern or "lee" side (assuming a glacier to have followed the course of the water) is a submerged valley over 40 metres deep. The Lake of Annecy exhibits another very singular feature. Near its northern end the bed deepens very rapidly from 30 to 80 metres; this funnel-shaped cavity is less than 200 metres in diameter, and is probably a submerged swallow hole. These notes may, it is hoped, suffice to indicate the importance of this work. The gratitude of students is due to M. Delabecque for supplying them with a valuable group of facts, the collection of which must have entailed great labour. These, however, appear to me not to lend themselves very readily to the support of the glacial excavation hypothesis; but to be more favourable to that which regards the larger Alpine lakes as mainly formed by movements of the earth's crust after the erosion of the valleys in which they lie.

T. G. BONNEY.

Dust Photographs.

IN Mr. Croft's paper on "Breath Figures," printed in NATURE for December 22 of last year (pp. 187, 188) he states:—"Two cases have been reported to me where blinds with embossed letters have left a latent image on the window near which they lay." The statement is not quite clear as I do not understand whether the letters were in contact with the glass or not.

Perhaps it may be interesting to place on record an observation of my own, made a few years ago, which struck me at the time as curious, but which I have not been able to verify since.

At the stations of the District Railway there is a useful arrangement by which passengers are informed of the destination of the next train. It consists of a shallow box with glass sides into which by a mechanical contrivance boards are let down on which the names of the stations are painted in white letters on a blue ground. The board with the words 'INNER CIRCLE' is most frequently exposed. At night the box is (or was) illuminated obliquely on either side by a tolerably powerful lamp.

One night I was waiting for the train at the Victoria Station. There was some dislocation in the service; the destination of the next train was uncertain and the box was empty. On glancing at it somewhat sideways I was however astonished to see the words 'INNER CIRCLE' on the glass side of the box in quite clear dark letters on a pale illuminated ground. I drew the attention of one of the platform officials to it. He saw it with perfect distinctness, and seemed to think he had noticed it before. Of course when the apparatus is in full working order there is little opportunity for doing so.

---

[1] "Atlas des Lacs Français, Ministère des Travaux Publics." No publisher's name appears on the sheets, but I am informed by M. Delabecque that the Atlas can be obtained at Georg's Library, Geneva.

The only explanation I could think of was:—(i) that the light of the lamp had produced some molecular change in the paint coating the notice board; (ii) that this had affected differently the blue and the white paint; (iii) that the same cause had set up some differential electrical condition of the board and the glass; (iv) that a bombardment of particles of the blue paint had taken place on to the glass to which they had adhered; and that (v) the particles so adhering, by dispersing the light, produced the effect of the pale illuminated ground while the spaces occupied by the letters being relatively clean stood out dark.

Royal Gardens, Kew, W. T. THISELTON-DYER.
February 1.

MR. W. B. CROFT's paper on Breath-Figures in your issue of December 22 reminded me of some curious impressions of monumental brasses which are to be seen on the walls of Canterbury Cathedral. When I saw these impressions a few years ago, it occurred to me that they might have been produced by mere contact, the brass plates having possibly been hung for many years against the walls, in secluded corners, at a time when the Reformers would not let them remain in their proper matrices on the church floor. I had forgotten the particulars of these figures, but Dr. Sheppard, of Canterbury, has kindly sent me the following notes by favour of Canon Fremantle:—"A number of impressions of brasses are in the basement (which is open to the air) under Henry IV.'s chantry in the Cathedral. A very good impression is on the western column of the crypt of Trinity Chapel. . . . On the walls appear the shapes of the effigies. Sometimes the stone is unstained all over the area of the figure, and surrounded by a broad dark smudge: and sometimes the case is reversed, and the figure is the exact negative of the former kind; that is to say, the area of the figure is indicated by an uniform dark tint, whilst the surrounding stone is unstained." Dr. Sheppard suggests "that an exact pattern seems to have been made in paper and then fixed to the wall whilst it was brushed over with linseed oil. But this does not account for the white effigies on a dark ground."

I would commend these impressions to the notice of those interested in the subject. It may be that, though some were made intentionally, others are the result of simple contact.

F. J. ALLEN.

Mason College, Birmingham, February 4.

Fossil Plants as Tests of Climate.

IN continuation of my recent letter, permit me to call attention to a communication on the bread fruit trees in North America, by Mr. F. H. Knowlton, of the National Museum, Washington, U.S., which appears in your American contemporary *Science* for January 13. The forty living species of *Artocarpus* are all confined to tropical Asia and the Malay Archipelago. *A. incisa*, the true bread fruit tree, and one or two others, are largely cultivated in the tropics. They are small or medium-sized trees with a milky juice, large leathery leaves, and monœcious flowers. The female flowers are long club-shaped spikes, which uniting form one large mass known as the "bread fruit," the interior containing a pulp when ripe like new bread.

The first fossil bread fruit was discovered in boulder county Colorado in late cretaceous rock, and was named by the late Prof. Leo Lesquereux *Myrica* (?) *Lessigiana*, other fragments he called *Aralia pungens*. The subsequent researches, or more perfect specimens of Dr. A. S. Nathorst, proved these to belong to one species, *Artocarpus Lessigiana*. Dr. Nathorst is the discoverer of another species closely allied to *A. incisa*, which he calls *A. Dicksoni*, which he obtained from the cretaceous flora of Waigatt, West Greenland, which the previous labours of Profs. Heer and Nordenskiöld had shown to be of a tropical or sub-tropical character, containing as it does numerous species of ferns of the order Gleichenialeæ, and several species of cycas.

CHAS. E. DE RANCE.

H.M. Geological Survey, Alderley Edge, Manchester.

Lunar Rainbow in the Highlands.

THIS interesting phenomenon (a very unusual one in this latitude) was observed near here on the morning of the 3rd inst., about six a.m. The moon was two days past full, and was not shining particularly brightly, being obscured, except at considerable intervals, by driving mist and light clouds. The bow, however, was exceedingly well marked, and formed a singularly beautiful object, stretching as it did completely across the north-western end of Loch Oich, glimmering against the dark background of the mountains, and sinking into the water on the southern shore of the loch. The general colour of the bow was yellow deepening into orange, several of the prismatic colours, however, being intermittently visible, especially a tinge of violet on the upper side.

The Abbey, Fort-Augustus, N.B.

OPTICAL CONTINUITY.[1]

KEENNESS of sight is measured by the angular distance apart of two dots when they can only just be distinguished as two, and do not become confused together. It is usually reckoned that the normal eye is just able or just unable to distinguish points that lie one minute of a degree asunder. Now, one minute of a degree is the angle subtended by two points, separated by the 300th part of an inch, when they are viewed at the ordinary reading distance of one foot from the eye. If, then, a row of fine dots touching one another, each as small as a bead of one 300th part of an inch in diameter, be arranged on the page of a book, they would appear to the ordinary reader to be an extremely fine and continuous line. If the dots be replaced by short cross strokes, the line would look broader, but its apparent continuity would not be affected. It is impossible to draw any line that shall commend itself to the eye as possessing more regularity than the image of a succession of dots or cross strokes, 300 to the inch, when viewed at the distance of a foot. Every design, however delicate, that can be drawn with a line of uniform thickness by the best machine or the most consummate artist, admits of being mimicked by the coarsest chain, when it is viewed at such a distance that the angular length of each of its links shall not exceed one minute of a degree. One of the apparently smoothest outlines in nature is that of the horizon of the sea during ordinary weather, although it is formed by waves. The slopes of *débris* down the sides of distant mountains appear to sweep in beautifully smooth curves, but on reaching those mountains and climbing up the *débris*, the path may be exceedingly rough.

The members of an audience sit at such various distances from the lecture table and screen, that it is not possible to illustrate as well as is desirable, the stages through which a row of dots appears to run into a continuous line, as the angular distance between the dots is lessened. I have, however, hung up chains and rows of beads of various degrees of coarseness. Some of these will appear as pure lines to all the audience; others, whose coarseness of structure is obvious to those who sit nearest, will seem to be pure lines when viewed from the furthest seats.

Although 300 dots to the inch are required to give the idea of perfect continuity at the distance of one foot, it will shortly be seen that a much smaller number suffices to suggest it.

The cyclostyle, which is an instrument used for multiple writing, makes about 140 dots to the inch. The style has a minute spur wheel or roller, instead of a point; the writing is made on stencil paper, whose surface is covered with a brittle glaze. This is perforated by the teeth of the spur wheel wherever they press against it. The half perforated sheet is then laid on writing paper, and an inked roller is worked over the glaze. The ink passes through the perforations and soaks through them on to the paper below; consequently the impression consists entirely of short and irregular cross bars or dots.

---

[1] Extract from a lecture on "The Just-Perceptible Difference," delivered before the Royal Institution on Friday, January 27, by Francis Galton, F.R.S.

I exhibit on the screen a circular letter summoning a Committee, that was written by the cyclostyle. The writing seems beautifully regular when the circular is photographically reduced; when it is enlarged, the discontinuity of the strokes becomes conspicuous. Thus, I have enlarged the word *the* six times; the dots can then be easily seen and counted. There are 42 of them in the long stroke of the letter *h*.

The appearance of the work done by the cyclostyle would be greatly improved if a fault in its mechanism could be removed, which causes it to run with very unequal freedom in different directions. It leaves an ugly, jagged mark wherever the direction of a line changes suddenly.

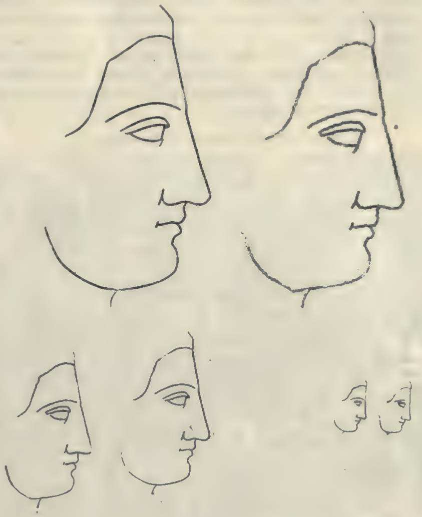
A much coarser representation of continuous lines is given by embroidery and tapestry, and coarser still by those obsolete school samplers which our ancestresses worked in their girlhood, with an average of about sixteen stitched dots to each letter. Perhaps the coarsest lettering that is ever practically employed is used in perforating the books of railway coupons so familiar to travellers. Ten or eleven holes are used for each figure.

A good test of the degree of approximation with which a cyclostyle making 140 perforations to the inch is able to simulate continuous lines, is to use it for drawing outline portraits. I asked the clerk who wrote the circular just exhibited to draw me a few profiles of different sizes, ranging from the smallest scale on which the cyclostyle could produce recognisable features, up to the scale at which it acted fairly well. Here are some specimens of the result. The largest is a portrait of 1½ inches in height, by which facial characteristics are fairly well conveyed; somewhat better than by the rude prints that appear occasionally in the daily papers. It is formed by 366 dots. A medium size is ¾ inch high and contains 177 dots, and would be tolerable if it were not for the jagged strokes already spoken of. The smallest sizes are ⅓ inch high and contain about ninety dots; they are barely passable, on account of the jagged flaws, even for the rudest portraiture.

I made experiments under fairer conditions than those of the cyclostyle, to learn how many dots, discs, or rings per inch were really needed to produce a satisfactory drawing, and also to discover how far the centres of the dots or discs might deviate from a strictly smooth curve without ceasing to produce the effect of a flowing line. It must be recollected that the eye can perceive nothing finer than a minute blurr of one three-hundredth part of an inch in angular diameter. If we represent a succession of such blurs by a chain of discs, it will be easily recognised that a small want of exactitude in the alignments of the successive discs must be unimportant. If one of them is pushed upwards a trifle and another downwards, so large a part of their respective areas still remain in line, that when the several discs become of only just perceptible magnitude, the projecting portion will be wholly invisible. When the discs are so large as to be plainly perceptible, the alignment has to be proportionately more exact. After a few trials it seemed that if the *bearing* of the centre of each disc from that of its predecessor which touched it, was correctly given to the nearest of the 16 principal points of the compass, N., NNE., NE., &c., it was fairly sufficient. Consequently a simple record of the successive bearings of each of a series of small equidistant steps is enough to define a curve.

The briefest way of writing down these bearings, is to assign a separate letter of the alphabet to each of them, *a* for north (the top of the paper counting as north), *b* for north-north-east, *c* for north-east, and so on in order up to *p*. This makes *e* represent east, *i* south, and *m* west.

To test the efficiency of the plan, I enlarged one of the cyclostyle profiles, and making a small protractor with a piece of tracing paper, rapidly laid down a series of equidistant points on the above principle, noting at the same time the bearing of each from its predecessor. I thereby obtained a formula for the profile, consisting of 271 letters. Then I put aside the drawing, and set to work to reproduce it solely from the formula. I exhibit the result; it is fairly successful. Emboldened by this first trial, I made a more ambitious attempt, by dealing with the profile of a Greek girl copied from a gem. I was very desirous of learning how far the pure outline of the original admitted of being mimicked in this rough way. The result is here; a ring has been painted round each dot in order to make its position clearly seen, without obliterating it. The reproduction has been photographically reduced to various different sizes. That which contains only fifty dots to the inch, which is consequently six times as coarse as the theoretical 300 to an inch, is a very creditable production. Many persons to whom this portrait has been shown failed to notice the difference between it and an ordinary woodcut. The medium size, and much more the smallest size, would deceive anybody who viewed them at the distance of one foot. The protractor used in making them was a square card with a piece cut out of its middle, over which transparent tracing paper was pasted. A small hole of about ⅛ of an inch in diameter was punched out of the centre of the tracing paper; sixteen minute holes just large enough to allow the entry of the sharp point of a hard lead-pencil were perforated through the tracing paper in a circle round the centre of the hole at a radius of ¼ inch. They corresponded to the 16 principal points of the compass, and had their appropriate letters written by their sides. The outline to be formulated was fixed to a drawing-board, with a T rule laid across it as a guide to the eye in keeping the protractor always parallel to itself. The centre of the small hole was then brought over the beginning of the outline, and a dot was made with the pencil through the perforation nearest to the further course of the outline, and this became the next point of departure. While moving the protractor from the old point to the new one it was stopped on the way, in order that the letter for the bearing might be written through the central hole.



A clear distinction must be made between the proposed plan and that of recording the angle made by each step from the *preceding one*. In the latter case, any error of bearing would falsify the direction of all that followed, like a bend in a wire.

The difficulties of dealing with detached portions of the drawing, such as the eye, were easily surmounted by employing two of the spare letters, R and S, to indicate brackets, and other spare letters to indicate points of reference. The bearings included between an R and an S were taken to signify directive dots, not to be inked in. The points of reference indicated by other letters are those to which the previous bearing leads, and from which the next bearing departs. Here is the formula whence the *eye* was drawn. It includes a very small part of the profile of the brow, and the directive dots leading thence to the eye.

The letters should be read from the left to the right, across the vertical lines. They are broken into groups of five, merely for avoiding confusion and the convenience of after reference.

U, V, T are points of reference.

By succeeding in so severe a test case as this Greek outline, it may be justly inferred that rougher designs can be easily dealt with in the same way.

At first sight it may seem to be a silly waste of time and trouble to translate a drawing into a formula, and then, working backwards, to retranslate the formula into a reproduction of the original drawing, but further reflection shows that the process may be of much practical utility. Let us bear two facts in mind, the one is that a very large quantity of telegraphic information is daily published in the papers, anticipating the post by many days or weeks. The other is that pictorial illustrations of current events, of a rude kind, but acceptable to the reader, appear from time to time in the daily papers. We may be sure that the quantity of telegraphic intelligence will steadily increase, and that the art of newspaper illustration will improve, and be more resorted to. Important local events frequently occur in far-off regions, of which no description can give an exact idea without the help of pictorial illustration; some catastrophe, or site of a battle, or an exploration, or it may be some design or even some portrait. There is therefore reason to expect a demand for such drawings as these by telegraph, if their expense does not render it impracticable to have them. Let us then go into details of expense, on the basis of the present tariff from America to this country, of one shilling per word, 5 figures counting as one word, cypher letters not being sent at a corresponding rate. It requires two figures to perform each of the operations described above, which were performed by a single letter. So a formula for 5 dots would require 10 figures, which is the telegraphically equivalent of 2 words; therefore the cost for every 5 dots telegraphed from the United States would be 2 shillings, or £2 for every 100 dots or other indications.

In the Greek outline there is a total of 400 indications, including those for directive dots, and for points of reference. The transmission of these to us from the United States would cost £8. I exhibit a map of England made with 248 dots, as a specimen of the amount of work in plans, which could be effected at the cost of £5. It is easy to arrange counters into various patterns or parts of patterns, learning thereby the real power of the process. The expense of pictorial telegraphs to foreign countries would be large in itself, but not large relatively to the present great expenditure by newspapers on telegraphic information, so the process might be expected to be employed whenever it was of obvious utility.

The risk is small of errors of importance arising from mistakes in telegraphy. I inquired into the experience of the Meteorological Office, whose numerous weather telegrams are wholly conveyed by numerical signals. Of the 20,625 figures that were telegraphed this year to the office from continental stations, only 49 seem to have been erroneous, that is two and a third per thousand. At this rate the 800 figures needed to telegraph the Greek profile would have been liable to two mistakes. A mistake in a figure would have exactly the same effect on the outline as a rent in the paper on which a similar outline had been drawn, which had not been pasted together again with perfect precision. The dislocation thereby occasioned would never exceed the thickness of the outline.

The command of 100 figures from 0 to 99, instead of only 26 letters, puts 74 fresh signals at our disposal, which would enable us to use all the 32 points of the compass, instead of 16, and to deal with long lines and curves. I cannot enter into this now, nor into the control of the general accuracy of the picture by means of the distances between the points of triangles each formed by any three points of reference. Neither need I speak of better forms of protractor. There is one on the table by which the ghost of a compass card is thrown on the drawing. It is made of a doubly refracting image of Iceland spar, which throws the so-called "extraordinary" image of the compass card on to the ordinary image of the drawing and is easy to manipulate. All that I wish now to explain is that this particular application of the law of the just perceptible difference to optical continuity gives us a new power that has practical bearings.

POSTSCRIPT.—A promising method for practical purposes that I have tried, is to use "sectional" paper; that is, paper ruled into very small squares, or else coarse cloth, and either to make the drawing upon it, or else to lay transparent sectional paper, or muslin, over the drawing. Dots are to be made at distances not exceeding 3 spaces apart, along the course of the outline, at those intersections of the ruled lines (or threads) that best accord with the outline. Each dot in succession is to be considered as the *central point*, numbered **44** in the following schedule, and the couplet of figures corresponding

11	21	31	41	51	61	71
12	22	32	42	52	62	72
13	23	33	43	53	63	73
14	24	34	**44**	54	64	74
15	25	35	45	55	65	75
16	26	36	46	56	66	76
17	27	37	47	57	67	77

to the portion of the next dot, is to be written with a fine pointed pencil in the interval between the two dots. These are subsequently copied, and make the formula. By employing 4 for zero, the signs of + and − are avoided; 3, standing for −1, 2, for −2; and 1, for −3. The first figure in each couplet defines its horizontal coordinate from zero; the second figure, its vertical one. Thus any one of 49 different points are indicated, corresponding to steps from zero of 0, ±1, ±2, and ±3 intervals, in either direction, horizontal or vertical. Half-an-hour's practice suffices to learn the numbers. The figures 0, 8, and 9 do not enter into any of the couplets in the schedule, the remaining 51 couplets in the complete series of 100 (ranging from 00 to 99), contain 21 cases in which 0, 8, or 9 forms the first figure only; 21 cases in which one of them forms the second figure only, and 9 cases in which both of the figures are formed by one or other of them. These latter are especially distinctive. This method has five merits—medium, short, or very short steps can be taken according to the character of the lineation at any point; there is no trouble about orientation; the bearings are defined without a protractor, the work can be easily revised, and the correctness of the records may be checked by comparing the sums of the small coordinates leading to a point of reference, with their total values as read off directly.

A method of signalling is also in use for military purposes, in which positions are fixed by coordinates, afterwards to be connected by lines.

F. G.

BRITISH NEW GUINEA.[1]

MR. THOMSON'S work on British New Guinea has been looked for with some impatience. Now that it has come it falls short of our expectations. We had hoped for a comprehensive work marshalling into order and summarising the observations and investigations made in the British part of New Guinea, by so many missionaries, explorers, naval and government officers and scientific men, for many years. Instead of this we find that the book is made up almost entirely of the explorations during the past four or five years of the administrator, boiled down out of the official reports by Mr. J. Thomson, the secretary of the Queensland branch of the Geographical Society of Australasia. Throughout the volume there is everywhere evidence that its author is new to literary composition. In consequence, the terse and vigorous English of the original reports suffers severely in the process, so much so that we regret that their important parts have not been presented to us as extracts in the explorer's own words. Mr. Thomson has himself never visited New Guinea, if we may judge by internal evidence, although his phraseology in many places is not unlikely to lead the reader to suppose that he has had a share in the results presented in its pages. Had the author had some personal acquaintance with the country of which he writes he would have formed opinions, we believe, different from many of those he has expressed on his own account throughout the book.

The work opens with a sketch "of the historical aspects of the whole of the great Papuan land," but we miss in it the names of many who deserve honourable mention for their contributions to the "making" of New Guinea. We find no mention of the investigations of Dr. Otto Finsch carried on in all three possessions, of those of Mr. O. Stone, of the missionaries in Geelvink Bay, of Mr. Romilly, of the Special Commissioners Sir Peter Scratchley and the Hon. John Douglas, of Mr. Milman, and of Commanders Pullen and Field, who have all contributed to our knowledge of different regions. This chapter is prefaced by a quotation from the writings of Plinius Minor:—"It appears to me a noble employment to rescue from oblivion those who deserve to be eternally remembered, and by extending the reputation of others, to advance at the same time our own." These words are the true key-note of the book from which our Brisbane Pliny—Plinius Major—has never once deviated throughout his task. It is doubtless no small compliment to any man to have his deeds held up in the light of "eternal remembrance" by one of his fellows, but the task requires the delicate hand of a judicious fellow; and we fear that our Pliny has marred the compliment in the paying. So inspired with veneration for his patron is he that every act of his appears almost extraordinary, and his name too august ever to be mentioned without the humblest obeisance expressed in the constant recapitulation of his titles, dignities, and office, which must be as nauseous to

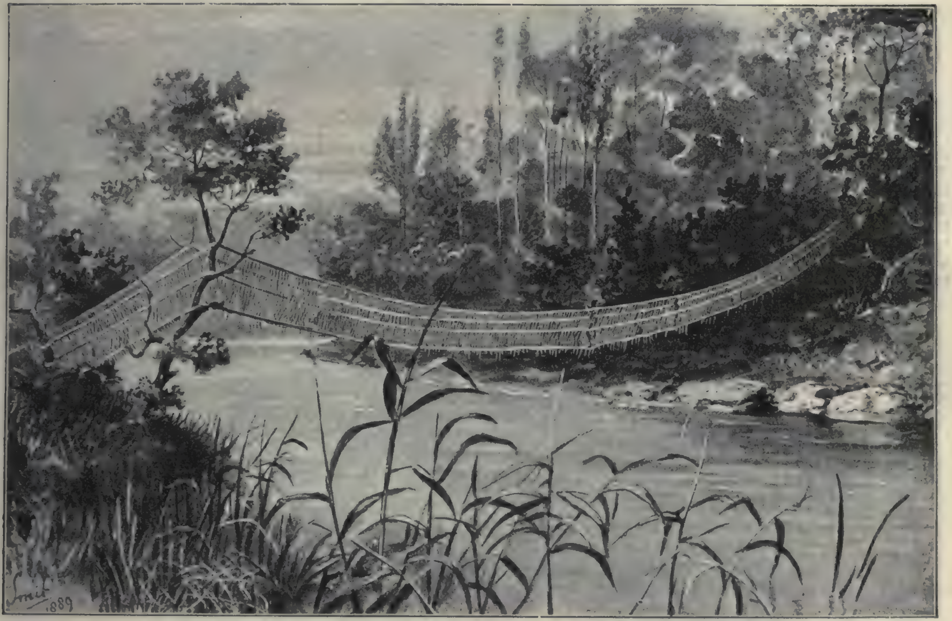

FIG. 1.—Native suspension bridge across the Vanapa river.

---

[1] "British New Guinea." By J. P. Thomson, F.R.S.G.S., &c. (London: George Philip and Co., 1892.)

that officer as to every reader of Mr. Thomson's book. In this "noble employment," however, we hope that our historiographer for Papua may reap the reward hoped for by his prototype.

The next two chapters deal with Sir William Macgregor's explorations in the Louisiade and D'Entrecasteaux archipelagoes. In Chapter IV. is an account of the pursuit and punishment of the natives of Chads and Cloudy bays for the murder of European traders visiting their shores. The country lying to the south-east and north-west of Port Moresby forms the subject of the following two chapters. Speaking of that portion to the south-east Mr. Thomson says, "It may not be altogether unreasonable to assume that in the future . . . fields once the scene of battle and feudal strife may be beautified by sites of local industry and manufacture, and enlivened by the joyous shouts of merry children and the harmonious peals of village bells." Quite forgetful of this happy picture, which he thinks is reasonable to expect, he sums up in the closing lines of his recapitulatory chapter the climatic aspects of the possession as "of an exceptional character, and their influence on Europeans so severe that very few constitutions can withstand their effect, a feature which will always be a great hindrance to settlement and a constant menace to life"—quite the region likely to produce European homes noisy with the "joyous shouts" of "merry children"! It is difficult to comprehend why Australian writers on New Guinea will so persistently—for Mr. Thomson is not the only author who thus sins, nor have we quoted the only specimen of this style of writing in his book—overlaud the capabilities and "the vast natural and artificial resources" of the country, heedless whether they may induce their too trustful readers to embark in hopeless enterprises in this "never, never land."

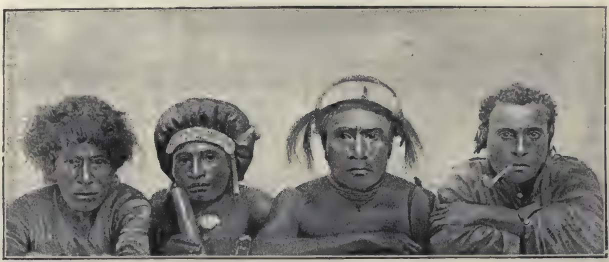

Fig. 2.—Highlanders of Mount Musgrave.

The seventh chapter, containing an account of Sir William Macgregor's splendid feat of the ascent of Mount Owen Stanley, is naturally the most interesting portion of the book. During this expedition almost if not *the* only native bridge yet known in New Guinea was met with. It was suspended from trees on each bank, and is very similar in every respect to those built by the Malays of Sumatra and the Dyaks of Borneo. How elegant and picturesque a construction it is may be seen by the illustration on page 345.

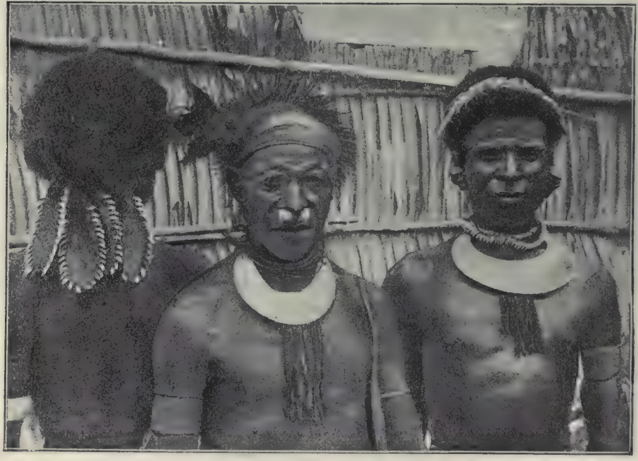

Fig. 3.—Fly River natives.

On Mount Musgrave friendly relations were established with the highland tribes, and a photograph of great interest and value, which we are personally in a position to pronounce very characteristic, was obtained by Mr. Goodwin. This also, through the courtesy of the publishers, we are enabled to reproduce here (Fig. 2). Sir William

Macgregor says that the features of these people, which are "remarkably good, indicate more character and strength than those of the coast man, and the cheek bones in many are rather broad and prominent. The nose is generally of the semitic type, with nostrils either not arched or much more so than is usual in Papuans. The chin and under jaw are stronger." They may be compared with the Fly river people, also here figured (Fig. 3).

European names were bestowed on the chief physical features of the country passed through by the expedition "of necessity," because of its "entire unacquaintance with their orthography (*sic*) through limited intercourse with the native inhabitants." This being in Dr. Macgregor's case evidently a right and sufficient reason for the nomenclature bestowed, how can Mr. Thomson with justice animadvert, as he does on an earlier page, on the fact that "the most important affluents [of the Kemp-Welch river] have received [from Mr. Cuthbertson] European appellations ? . . . . This disregard of the native nomenclature is, in the interests of geography, much to be regretted." However, we are pleased to learn that the European names selected by the administrator have been bestowed "upon the broadest national sentiment, as being compatible with the principles which prompted the bestowal of an English name on the range by the officers of H.M.S. *Rattlesnake*." It is not improbable that the explorer of the Kemp-Welch felt the same necessity, and was actuated by the same broad sentiment. Evidently the actor here sanctifies the act. We must, however, take exception to the statement made by Mr. Thomson that it was to the *range* that the name Mount Owen Stanley was given. It is evident from observations in his book, that the author is aware of the discussion that followed on the reading of Dr. Macgregor's paper on his ascent of the mountain before the Royal Geographical Society in London. On that occasion the president of the society clearly pointed out that this name was bestowed, as has been marked on all maps for forty years, on the *peak*, not on the *range*. Throughout the book this imperious disregard for nomenclature is exhibited. D'Albertis' name of Snake Point in the Fly river has without reason been changed to D'Albertis Junction; Annabel Harbour, close to Boundary Cape, although marked on the official map of Sir Peter Scratchley's voyage to the north-east coast, becomes Douglas Harbour; Fort Harbour, Clayton Inlet in Porlock Bay, and the peaks named on the same occasion, as well as the region delineated by the present writer at the base of Mount Owen Stanley, are also all ignored on the map attached to the volume now being considered. One fails to comprehend what principle except personal feeling the author has followed, on the one hand in his agreeing to the change of the thoroughly established Mount Owen Stanley to a new name, and on the other, in his restoring to the Aird river, which had recently been re-christened the Douglas, the name given to it by Captain Blackwood half a century before. Not only are these arbitrary changes an unwarrantable violation of the laws of nomenclature, but they are in the remover an illegitimate assertion of authority over previous fellow-explorers, as well as an assumption of an honour to which he has no title.

Mr. Thomson has drawn on the face of his map two large red circles, from purely arbitrary centres of the equally arbitrary radius of 6° 8′ 56″, which are tangential somewhere in the valley of the Strickland river. It is impossible to divine their purpose, except perhaps to form a seasonable puzzle for his readers.

The writer of this notice feels entitled to remark on the following observation, occurring on page 109:—"Although great care was exercised, the expedition was unable to identify places on the Owen Stanley range, named and described by Mr. Forbes. We are reluctantly constrained to omit these names." In the Proceedings of the Royal Geographical Society, which Mr. Thomson quietly ignores, the writer has already pointed out that along the route by which the administrator approached Mount Owen Stanley, it would have been impossible to have seen the features "named and described by Mr. Forbes." Mr. Thomson, posing as a court of geographical appeal, has graciously condescended to intimate that if these names had been "judiciously and appropriately applied to well-defined places," they "would have received full recognition" from him. "It is also," he continues, "regretable that in describing localities to which he assigns positions, that explorer has omitted to supply the data employed in their determination." To every unprejudiced person it must be evident that the map published by the writer could not have been plotted in England without data, any more than that of Sir William Macgregor, who has not supplied to the general public, so far as the writer knows, the data by which his localities are fixed. It will be time, however, to submit to Mr. Thomson these data, when it is acknowledged that a back parlour critic of a country in which he has never set foot is a competent judge of either the judiciousness and appropriateness of the names applied, or the accuracy of the localities, or the data on which they are based.

Chapters VIII., IX., and X. are devoted to an account of the administrator's ascent of the Fly river, and of his visit westwards to the Anglo-Dutch boundary, and the eleventh to his voyage along the north-east coast. D'Albertis long ago gave us a very accurate account of his 400 mile navigation of the Fly river. Sir William Macgregor carried his flag right to the German territory, and added several unknown rivers and new mountains to the map; but both in this region, as on the north-east coast, his voyages, though they contributed many additional facts, added little essentially new to the observations of his predecessors, except his account of the piratical Tugere tribe, living on our boundary line west of the Fly river, of whom so much had been heard but so little known.

This handsome volume, which presents us in a collected form with the record of the important contributions, geographical and biological, of a most energetic officer, to our growing knowledge of New Guinea, would have been more valuable and welcome, even in its restricted range, but for the bias unduly exhibited throughout its pages, the verbiose platitudes by which it is marred, and the extreme looseness of its descriptions, as "Morna [an island] is of the usual formation," "features of oriental type," "the Papuan dialect," and such-like expressions, which are numerous. In a long appendix we have a *résumé* of the results of the geological, botanical, and some of the zoological collections made by Sir W. Macgregor and others. Of these the chapter by Mr. Etheridge, Government Palæontologist of New South Wales, is specially valuable. Several important zoological groups, however, such as the birds, are, curiously enough, entirely disregarded. Vocabularies of many of the dialects spoken in widely separated districts of the possession are given, and are very valuable, and we sincerely hope that no opportunity may be lost of amplifying them. In fine, we regret to feel that this work will not yet relieve those who desire to make themselves acquainted with the accurate and complete history of British New Guinea, from the labour of searching through the original reports of the explorations, not of the administrator alone, but of the many other equally trustworthy workers who have contributed to its records.

HENRY O. FORBES.

NOTES.

PROF. R. VIRCHOW will deliver the Croonian lecture before the Royal Society on March 16, the subject to be the position of pathology among the biological sciences.

We greatly regret to have to announce the death of Mr. G. M. Whipple, Superintendent of the Kew Observatory. He died on Tuesday night after a long illness.

The *Journal of Botany* records the death, on January 18, at Brighton, of Dr. Benjamin Carrington, the highest authority on British Hepaticæ.

Dr. H. J. Johnston-Lavis has been appointed Professor of Vulcanology in the University of Naples. A chair of vulcanology existed for some time at Catania, but was abolished on the death of Prof. Silvestri.

Some important work with regard to technical education in London was done by the London County Council on Tuesday. The Council began the consideration of the recommendations of the special committee appointed to investigate the subject, and adopted the following proposals—that the Council should devote to technical education some portion of the funds from time to time recoverable under the Local Taxation (Customs and Excise) Act, 1890; that, in order to promote efficient and united action, it is desirable that the Council should delegate, so far as is permitted by law, its powers in respect of technical education to a composite body, to be called the Technical Education Board, to be appointed by the Council, partly from its own members and partly from other persons whose co-operation is desired; and that the Board should be appointed for a term of three years. It was agreed that the City Companies should be asked to contribute to the funds for technical instruction a fair proportion of their corporate income as distinguished from their trust property.

On Saturday the overhead electric railway at Liverpool was opened by Lord Salisbury, who afterwards delivered a very effective speech on the great things which are likely to be achieved for mankind by electricity.

The London Amateur Scientific Society will hold its annual general meeting on Friday, February 10, at 7.30 p.m., at the Memorial Hall, Farringdon Street. The president will deliver an address, and the officers and council for the ensuing year will be elected. At the conclusion of the annual general meeting the ordinary meeting will be held, when objects of interest—botanical, zoological, and geological—will be exhibited.

A conversazione was held the other evening at Firth College to celebrate the completion of the additional building. The addition comprises new physical and biological laboratories, workshop and class rooms, and considerably increases the accommodation available for teaching purposes. The cost, £5,500, has been wholly raised from local subscriptions.

Another disastrous shock of earthquake occurred at Zante on Friday last. It was followed by a terrific thunderstorm, accompanied by rain and hail. All the ovens in the island were destroyed by the successive shocks, so that no bread or biscuits could be made. Thousands of the inhabitants have been made homeless. On Monday there were three further shocks. The King and Queen of Greece have visited several of the villages, and have been deeply affected by the scenes of utter ruin and desolation which have everywhere met their eyes. On Tuesday they visited the naphtha springs of the island, which are believed to be the centre of the disturbance. The mayor of the village of Deme Elatia, some distance from the town of Zante, telegraphed that a large chasm, from which smoke was constantly issuing, had been discovered near that place.

During the first part of the past week the weather in these islands was under the influence of barometrical depressions situated in the north-west. Rain fell in most places, and the temperature exceeded 50° in the south and west, and even reached 56° in London. On Friday an anticyclone which lay over the Baltic, spread westwards, and under its influence the temperature became much lower, sharp frosts occurring at night over England, the readings on the grass in the southern part falling as low as 17°, but in the north and west the day temperatures were between 45° and 50°. The weather in the southern parts of the country became bright and fine, with local fogs, which extended as far as central England. During the early part of this week depressions from the Atlantic again skirted our western coasts in a north-easterly direction, causing south-westerly gales in the north and west, and a considerable increase in temperature, the maxima on Monday exceeding 50° in Ireland and the extreme south-west of England. The depression rapidly increased in intensity, and by Tuesday the warm south-west winds had spread over the whole country, the rise of temperature amounting to over 20° in the south-east of England. A bright aurora was observed in the north-east of Scotland on Sunday night. The *Weekly Weather Report* of the 4th instant shows that the temperature exceeded the mean in all districts during that week. Bright sunshine did not differ materially from the mean in any district, the percentage of possible duration ranged from twenty-five in the south-west, to twelve in the east of England.

The *American Meteorological Journal* for January contains an article by Prof. D. P. Todd bearing upon the selection of stations for observing the total eclipse of April 16 next, together with a map showing the entire region of visibility. He has gone to considerable trouble in collecting data, especially cloud observations for the month of April, for the last three years, together with particulars respecting the stations and the best means of reaching them. The utility of a systematic examination of the cloud conditions of the eclipse localities is apparent. It is only in this way that the best observing stations can be selected.

The meeting of the American Psychological Association at the University of Pennsylvania on December 27 and 28 seems to have been very successful. According to a writer in the New York *Nation*, no one who attended the meeting failed to be impressed with the quite unusual enthusiasm of the members and the still more unusual peace and serenity that prevailed in all the discussions. This writer is of opinion that, apart from Dr. Sanford's observations on dreams, the paper of most general interest was President Hall's account of the history and prospects of experimental psychology in America. A "breezy stimulus" was brought to the meeting by Prof. Hugo Münsterberg, of Harvard, who has recently gone from Freiberg to be director of the Harvard Psychological Laboratory. He stirred up a vigorous discussion upon the very foundations of experimental research. This discussion, as well as others, was enriched by the contributions of Prof. Titchener, of Cornell. The next meeting of the association is to be held at Columbia College, New York, during the Christmas recess, 1893.

The Annual Report of the Botanical Department, Jamaica, has just been published. The Director, Mr. W. Fawcett, F.L.S., has a good deal to say about the work of his Department, one of the oldest and most successful in the colonies. It was started as long ago as 1777, and ever since, as Mr. Fawcett recalls, it has successfully "introduced valuable exotics, and the productions of the most distant regions to the West Indies," and laid the foundations of the present prosperity in place of the poverty which followed the abolition of slavery. The work of establishing the Hope Gardens as the headquarters of the Department near Kingston is still kept in view, although the amount allowed for this purpose appears much less than the Director considers desirable, taking into account the present importance of the island. A hill garden is looked upon as essential to the development of the high lands in Jamaica, and Mr. Fawcett shows that as about one-half of the total area of the island is above 1000 feet elevation, it is impossible to ignore the legitimate claims of those who are engaged in cultural industries above that limit. Good progress has been made in the scientific work connected with the herbarium and library, and numerous subjects, such as the extension of grape culture, the distribution of valuable economic plants, experiments in onion and tomato culture, fodder plants for the hills, have received attention. Students from Harvard University were engaged during the year in studying and making collections of tropical plants, and one of these devoted himself to preparing glass models of flowers and fruits with dissections to illustrate the science of botany. Two apprentices, natives of Lagos, West Africa, were attached to the Hope Gardens, with the view of qualifying themselves to take charge of botanical stations in their own country.

Mr. Fawcett's opinion respecting the practical aims and functions of departments like his are conveyed in the following words: "Botanic Gardens in the tropics do the work on the plant side of Agricultural Departments in temperate climates. They are in themselves experimental stations, and are much more efficient in introducing new cultural products, and in distributing plants and imparting useful information than most agricultural departments. The whole of the Botanic Gardens in the British Empire are more or less in communication with one another, exchanging seeds and publications, and all look up to the Royal Gardens at Kew as to their head for advice and assistance. Imperial Federation is already in existence as regards the Botanical Gardens and their work. If any special variety of plant or any new culture comes into notice information and plants are sought either directly from the local institutions, or more probably through Kew as the botanical clearing house. The Director of Kew has at his disposal the services of experts in every branch of botanical inquiry, and he is always most willing to assist colonial establishments in every way. Besides, any intricate question that arises in chemistry, in diseases of plants, in insect pests, in the commercial value of new products, can nearly always be determined by reference to Kew. Colonial botanical gardens are therefore not isolated units, but branches of an organisation as wide as the British Empire itself."

The first part of "A Handbook to the Flora of Ceylon," by Dr. H. Trimen, F.R.S., director of the Royal Botanic Garden, Paradenyia, will shortly be published. It will be illustrated by twenty-five coloured plates, and the entire work is intended to consist of four similar parts.

The first number of *Erythea*, a new monthly botanical journal for Western America, has been published. It is edited by Mr. Willis L. Jepson, under the direction of members of the botanical department of the University of California.

Mr. T. Southwell records in the February number of the *Zoologist* the occurrence of Sowerby's whale (*Mesoplodon bidens*) on the Norfolk coast. On December 19 last he received a telegram stating that a strange "fish" was ashore at Overstrand, near Cromer; and on the following day he and Mr. S. F. Harmer, of the Museum of Zoology and Anatomy, Cambridge, went to Overstrand, where they found an adult female of this rare species. About 8 a.m., on Sunday, December 18, one of the Overstrand fishermen saw from the cliff an object lying in shallow water near the beach, which he at first took to be a log of wood, but soon perceived to be a large "fish." After obtaining assistance, he fastened a noose over its tail and secured it by an anchor, till it was placed on a trolley and drawn up the gangway to a shed on the cliff where the visitors saw it. The animal was alive when first observed, but died before it was taken from the water. Before the arrival of the visitors it had been eviscerated, and a very advanced fœtus removed from it. The total length of the old female, measured in a straight line to the centre of the tail, was 16 feet 2 inches, and that of the young one 5 feet 2 inches; across the flukes of the tail the adult measured 3 feet 8 inches. The present, says Mr. Southwell, is the nineteenth known example of this remarkable animal, all of which have been met with in the North Atlantic during the present century; but, with the exception of one taken in 1889 at Atlantic City, which came into the possession of the United States National Museum at Washington, and of which no account has, he believes, at present been published, in no other instance has an example in perfect condition come under the notice of a cetologist. Individuals or their remains have been found in Scotland and Ireland, but the only previous English example was met with at the mouth of the Humber in September, 1885.

Colonel H. W. Feilden, in the course of an interesting paper on animal life in East Greenland, contributed to the February number of the *Zoologist*, suggests, as he has done before, that the Musk-ox might with advantage be introduced into Great Britain. He sees no reason why it should not thrive on the mountains of the Highlands of Scotland. In the winter season the Musk-ox is covered with a long-stapled fine wool in addition to its coat of hair. This wool is of a light yellow colour, and as fine as silk. Sir John Richardson states that stockings made from this wool were more beautiful than silk ones. Young Musk-oxen are very easily reared and tamed, and, Colonel Feilden thinks, there could not be any great difficulty in catching either old or young in Jameson's Land.

Governor Flower has recommended that all of the New York State's pecuniary contributions to agriculture should be turned over to Cornell University, with power to apply the same in such a manner as the trustees and faculty of that institution may devise. To the New York *Nation* this seems an excellent suggestion. The agricultural disbursements from the State Treasury, except the portion specifically set apart as premiums for agricultural fairs, have become, it says, as distinctly a part of the "spoils system" of politics as the work on the canals or the appointments of wardens in the State prisons. The Dairy Commission was started with an appropriation of 10,000 dollars for the purpose of suppressing oleomargarine. The expenditure has grown to 100,000 dollars per year, while the fight against oleomargarine is not a whit more effectual than it was in the beginning.

The Government of Cape Colony has now at work, in charge of its own experts, eight water-boring diamond drills, and there is a great demand on the part of farmers for the use of the instruments. Experiments have been made on twenty-seven farms, on twenty-two of which water has been found. The *Agricultural Journal* of Cape Colony says that the results have sometimes been astonishingly successful. On a farm in the division of Colesberg, for instance, three holes were sunk, the first two unsuccessfully. In the third, however, the water was struck, first at 2 feet 6 inches, then at 8 feet 6 inches, then at 16 feet, then 22 feet, then 32 feet 6 inches, and on reaching a depth of 47 feet a stream of water shot up above the ground, gauged at 21,600 gallons in twenty-four hours, delivered through a 1-inch pipe, and with every indication of the supply proving permanent. In most cases the water is of excellent quality. Some exceedingly interesting experiments are about to be tried in Bushmanland by the Government. Sites are now being selected for a line of boreholes right across the country. It is well known that the veld makes splendid sheep-runs after occasional rains, and should the experiments prove successful, the value of the land will be greatly increased. With respect also to the Government railway grant of 6000 square miles of land in Bechuanaland, it is intended that water shall be bored for there as soon as drills can be set at liberty.

Prof. O. C. Marsh gives in the February number of the *American Journal of Science* an interesting restoration of

Anchisaurus, the skeleton chosen for the purpose being the type specimen of *Anchisaurus colurus*, which the writer has already described. This restoration, as shown on an accompanying plate, indicates that *Anchisaurus colurus* was one of the most slender and delicate dinosaurs yet discovered, being only surpassed in this respect by some of the smaller bird-like forms of the Jurassic. The restoration, Prof. Marsh thinks, will tend to clear up one point long in doubt. The so-called "bird-tracks" of the Connecticut river sandstone have been a fruitful subject of discussion for half a century or more. That some of these were not made by birds has already been clearly demonstrated by the fact that the impressions of fore feet, similar to those made by reptiles, have been found with them. Although no osseous remains were found with them, others have been regarded as footprints of birds, because it was supposed that birds alone could make such series of bipedal, three-toed tracks and leave no impression of a tail. It is now evident, however, says Prof. Marsh, that a dinosaurian reptile like *Anchisaurus* and its near allies must have made footprints very similar to, if not identical with, the "bird-tracks" of this horizon. On a firm but moist beach, only three-toed impressions would have been left by the hind feet, and the tail could have been kept free from the ground. On a soft, muddy shore, the claw of the first digit of the hind foot would have left its mark, and perhaps the tail also would have touched the ground. Such additional impressions the writer has observed in various series of typical "bird-tracks" in the Connecticut sandstone, and all of them were probably made by dinosaurian reptiles. No tracks of true birds are known in this horizon.

THE U.S. Secretary of the Interior, in his report, just issued, for the fiscal year ending June 30, 1892, refers to a good many subjects of more than passing interest. Speaking of Indian educational work during the year, he states that it has been greatly extended and improved. The attendance of Indian children in school has increased over 13 per cent., the enrolment for 1892 being 19,793 as against 15,784 in 1889. Five new Indian reservation boarding schools have been established during the present administration, and are in successful operation, and six others are in process of establishment, and it is anticipated will be opened soon. Six non-reservation schools have also been established and others are being prepared. The standard, character, and ability of all *employés* have been greatly improved, as have also the appliances and equipments for the proper training of Indian pupils and the efficient administration of the Indian school service. A uniform system of text-books and course of study has been adopted, and a compilation of the rules for the conduct of the schools has been prescribed. The interest in the welfare of the Indians has been constant and the work in their behalf persistent; and the Secretary thinks that this has resulted in their being raised still nearer to civilisation.

THE U.S. Geological Survey, according to the Secretary for the Interior, has had a very marked effect on the mining industries of the country. The increase in value of mineral products during the past year was 75,000,000 dollars, and the increase during the thirteen years since the institution of the survey is 300,000,000 dollars. While a part of this development represents the normal growth of the population and industries, the increase is much more rapid than that of population, and is, moreover, accompanied by a decided relative decrease in importations of mining products; indeed, the mining products of the country have more than doubled during the past thirteen years, while the population has increased only 30 per cent. The secretary, therefore, thinks it fair to ascribe a material part of the present industrial activity in extracting and utilising mineral resources to the services of the Geological Survey through its correspondence, and especially through its widely distributed maps and reports. The cost of mineral production during the past year has been reduced about 15 per cent., and during the period since the institution of the survey no less than 40 per cent., a saving to the consumers of mineral products amounting to millions of dollars annually being thus effected. A considerable part of this saving must be ascribed to the diffusion of exact information concerning mineral localities by the geological surveys of the Federal Government and several of the States.

DEALING with the state of the Seal Islands, the Secretary for the Interior says that during the season of 1892 only 7500 seals were killed on the islands, and that the diminished number of seals upon the rookeries shows the terrible waste to seal life in the destructive methods employed in pelagic sealing. Heroic measures, he maintains, are necessary for the preservation of the sealing industry. In 1890 no less than 50,000 seals were taken in the sea, and more than that number in 1891. Every seal taken in the ocean represents many more destroyed, and the 52,087 taken in the ocean in 1891 indicates the destruction of 300,000 more, three-fourths of which were females.

THE accumulation of ice in winter, blocking harbours, estuaries, &c., interferes greatly with the commerce of Northern peoples. The idea arose to make steamers which should break a temporary path through the ice, and in Gothenburg (Sweden) such a vessel was built in 1881. In the severe winter of 1885 it made a wide passage between that town and Vinga, on the open sea, through an ice-bank about a foot thick, which it charged at a speed of about 8½ knots an hour. Christiania has been led to get one of these ice-breaking steamers; also Oersen in Denmark, and Stockholm. The *Murtaja*, recently built for Stockholm (and described in *Génie Civil*), acts both by its weight in charging the ice-bank, and by its spoon-like bow resting on the ice and crushing it. The hull is divided into compartments, those at the bow and stern serving as reservoirs for water, which is transferred from the one to the other by a pump. With the stern-reservoir full, the draught of water at the stern is about 21 inches; at the bow about 15 inches. When the bow rises on the ice the water is quickly brought forward to add to the weight. It need hardly be said the bow, and indeed the whole of the hull, are made very strong, the material used being Swedish scrap iron and Martin steel.

IT is known that sewage water, spread over irrigation-fields, reappears from drains placed at a few feet depth, in a limpid state, like spring water. This water, unlike that of sewers, proves remarkably favourable to fishes, probably because of its dissolved organic matter, which the filtration in the soil has not wholly removed. This fact has been lately observed by Herr Oesten on the irrigation farm at Malchow, near Berlin, where the water is collected in eight ponds; and in these ponds salmon and carp have flourished greatly.

IN determining the thermal conductivities of liquids, two methods have been employed. In the one, a column of liquid is warmed at the top and the rate of propagation downwards through the column is observed. In the other, the lamellar method, which was first employed by Guthrie, a thin layer of liquid is placed between two conducting surfaces. Mr. R. Wachsmuth has shown, by means of an ingenious piece of apparatus, that in the first method currents in the liquid are unavoidable. The apparatus, as described in *Wiedemann's Annalen*, consisted of a beaker placed inside another containing water. The inner beaker was filled with water and blue iodide of starch, which has the property of suddenly turning colourless when heated to a temperature somewhere between 30° and 70°C. according to the degree of dilution. A copper cylinder was placed on the rim of both beakers so that its bottom was in contact with the surface of the emulsion. When steam was made to pass through the cylinder, a colourless stratum was seen to extend downwards from the surface. The separating surface was sharply defined at first, but after a few minutes a number of secondary stratifications appeared, which on close inspection showed wavy outlines. Many of them were of a deeper blue, *i.e.* cooler, at their upper than at their lower surfaces, so that there was evidence of a vortex-like motion in the liquid. For really trustworthy results Mr. Wachsmuth used an arrangement of two copper plates and a thermopile, the lower plate being placed in contact with ice.

THE volume on "The Partition of Africa," by Mr. J. Scott Keltie, which has been for some time in preparation, will be issued in a few days by Mr. Stanford. The work, which has been brought thoroughly up to date, is illustrated by a carefully-selected series of facsimiles of early maps, as well as by a number prepared specially to show the present condition of the continent in its many different aspects.

MR. A. E. SHIPLEY, Fellow of Christ's College, Cambridge, and Demonstrator of Comparative Anatomy in the University, has been for some time engaged on an illustrated text-book of invertebrate zoology, which will be published (Adam and Charles Black) early in the spring. It is specially adapted for the use of University students reading for such examinations as the first part of the Natural Sciences Tripos, or for the B.Sc. degree in London.

MESSRS. MACMILLAN AND CO. have published a second edition of Mr. D. E. Jones's "Examples in Physics." The book has been carefully revised, and some sixty pages of matter have been added. New sets of problems from recent papers have been put in the place of the examination questions at the ends of the chapters.

THE first volume of the *Seismological Journal* is now in the press, and will shortly be issued. It is uniform in size and in character with the Transactions of the Seismological Society, and will correspond with what would have been volume XVII. of those publications had they been continued. The yearly subscription for the journal is 5 yen, 5 dollars, or £1. This includes delivery or postage. It may be paid by P.O.O. or a draft on any foreign bank in Yokohama. Address, John Milne, 14, Kaga Yashiki, Tokio.

MESSRS. WHITTAKER AND CO. have published "The School Calendar and Handbook of Examinations, Scholarships, and Exhibitions, 1893." This is the seventh year of issue. A preface is contributed by Mr. F. Storr.

A DEFINITELY crystallised compound of iron and tungsten of the composition FeW_2 is described by Drs. Poleck and Grützner, of the University of Breslau. The crystals of this interesting substance were discovered in drusy cavities of a massive piece of a crystalline iron-tungsten alloy containing no less than 80 per cent. of tungsten. The alloy had been prepared by an electrolytic process from *wolframite* at the works of Biermann's Metal Industry in Hanover, and exhibited in the numerous cavities small but very well-formed crystals of a silver-grey colour and exhibiting very brilliant faces. They were extremely heavy and of exceptional hardness. Upon analysis they yielded numbers corresponding closely with those calculated for the compound FeW_2. Dr. Milch, of the Mineralogical Department of the University, subjected the crystals to a goniometrical investigation, and found them to consist of trigonal prisms whose faces were inclined exactly at 60°, and which were terminated by a basal plane inclined exactly at 90°. Singularly, however, no other faces were ever discovered upon them, so that it was impossible to ascertain to what sub-section of the hexagonal system the crystals belonged. The crystals are so hard that they readily scratch topaz, and appear to be of about the same hardness as corundum.

THE discovery of these crystals of a definite compound of iron and tungsten, and the fact that they are endowed with such a high degree of hardness, afford a ready explanation of the long-known property of tungsten in improving the hardness of steel. Berzelius, in his *Lehrbuch*, already remarked that tungsten readily formed alloys with most of the other metals, and in the year 1858 Muchet in this country took out a patent for the employment of tungsten in the manufacture of steel. Thereupon the wolfram minerals, previously considered as almost worthless, rapidly came to acquire a considerable value. Bernoulli has since shown that tungsten is capable of alloying in all proportions with iron until it reaches a proportion of 80 per cent., when the mass becomes infusible even at the hottest procurable white heat. This alloy containing so high a percentage of tungsten, approximating indeed to that (86·4) contained in the crystals above described, exhibits a silver-grey lustre like that of the crystals and possesses almost the same hardness, scratching glass and quartz with ease. Latterly the manufacture of this alloy has been carried on at the Hanoverian metal works above referred to, and brought into commerce. There can be little doubt that the remarkable property of tungsten in increasing the hardness of steel is due to the formation of more or less of this compound FeW_2, and the nearer the proportions of the two metals approach to those of the compound itself the more nearly does the resulting alloy approach in hardness to that displayed by the crystals of FeW_2 above described.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*, ♀) from India, presented by Capt. U. Cooke; a Two-spotted Paradoxure (*Nandinia binotata*) from West Africa, presented by Lady Fleming; a Brush-tailed Kangaroo (*Petrogale penicillata*, ♂), two Black-striped Wallabys (*Halmaturus dorsalis*, ♀ ♀) from New South Wales, presented by Mr. Wilberforce Bryant; a Mauge's Dasyure (*Dasyurus maugæi*) from Australia, presented by Mr. Robert Hoare; a Red and Yellow Macaw (*Ara chloroptera*) from South America, presented by Mr. H. H. Dobree; a Grey Parrot (*Psittacus erithacus*) from West Africa, presented by the Executor of the late Mrs. Bolaffe; an Æthiopian Wart Hog (*Phacochœrus æthiopicus*, ♂) from Matabeleland, South Africa, deposited; two Chukar Partridges (*Caccabis chukar*, ♂ ♀) from North-west India, presented by Major Ingoldsby Smythe; fourteen Prairie Marmots (*Cynomys ludovicianus*, 6 ♂ 8 ♀) from North America, an Arctic Fox (*Canis lagopus*) from the Arctic Regions, two Rufous Tinamous (*Rhynchotus rufescens*) from Brazil, purchased; three Black and Yellow Cyclodus (*Cyclodus nigro-luteus*), three Diamond Snakes (*Morelia spilotes*), a Short Death Adder (*Hoplocephalus curtus*), a Purplish Death Adder (*Pseudechis porphyriaca*), a North Australian Banded Snake (*Pseudonaia nuchalis*) from New South Wales, received in exchange.

OUR ASTRONOMICAL COLUMN.

COMET HOLMES (1892 III.).—During the past week no very important change has taken place in the appearance of the comet; the following is the current ephemeris:—

Ephemeris for 12*h*. *M. T. Paris.*

1893.	R.A. app.			Decl. app.		
	h.	m.	s.	°	′	″
Feb. 9	1	56	29·3	+34	0	28
10	1	58	3·3		2	18
11	1	59	37·8		4	12
12	2	1	12·8		6	9

Spectra of Planetary Nebulæ and Nova Aurigæ.—In the December number of the *Memorie della Società degli Spettroscopisti Italiani*, among many interesting communications, is one by M. Eugen Gothard, relative to the great similarity between the spectra of the late Nova and the planetary nebulæ. By the aid of a 10¼-inch reflector and a 10-inch objective prism, together with Schleussner's orthochromatic plates, he has been able to obtain these photographs, the wave-lengths of the lines of which are given in the table below. In the memoir copies of the photographs on a somewhat larger scale are given, that of the Dumb-bell nebula (G.C. No. 4447) showing the image of the nebula itself, just as if no prism had been used. The wave-lengths of the Nova given in this table were obtained from photographs taken on September 27 with 2h. 15m. exposure, and on October 28 with 3h. exposure, and, in M. Gothard's words, "gave the surprising result that the spectrum of the new star perfectly agrees with that of the planetary nebulæ."

The following is the table of the wave-lengths, lines I., II., VI., and VII. representing the nebula lines, and III., IV., and V. the hydrogen lines:—

		I.	II.	III.	IV.	V.	VI.	VII.
(1) G.C. No. 4447	—	502	—	434	411	396·5	386·5	373
(2) " 4964	—	501	470	434	409	397	386·5	—

Sun-spots and Magnetic Perturbations in 1892.—In an article under this heading in *Astronomy and Astrophysics* for January M. Ricco brings together the facts relative to these two phenomena, the magnetic perturbations being taken from the photo-magnetographs of the United States Naval Observatory. As the author describes in detail both kinds of observations, and in addition, a tabulated statement of the records, we cannot do better than abridge the table, by omitting the numerical statements as to the magnitudes of the spots and perturbations, leaving our readers to refer if necessary to the journal itself.

In the column "spots" this means principal spots; E denotes extraordinary; V.L, very large; L, large; M, medium; S, small; and N, none.

Transit Centre Meridian.	Spots.	Helio-graphic latitude.	Time of Maximum.	Mag. Pertur-bations.	Retar-dation in time.
		°			h.
Jan. 4, 2 p.m.	V.L	+20	Jan. 6, 4 a.m.	V.L	38
Jan. 28, 3 p.m.	L	−16	Jan. 29, noon	L	21
Feb. 2–4	N	—	Feb. 2–4	S	—
Feb. 12, 4 a.m.	E	−30	Feb. 14, 1 a.m.	E	45
March 1–5	N	—	March 1–5	M	—
March 7, 2 a.m.	N	—	March 7, 2 a.m.	L	—
March 10, 2 p.m.	E	−29	March 12, 11 a.m.	V.L	45
April 23, 8 p.m.	L	+11	April 25, 11 p.m.	L	51
April 24, 4 p.m.	L	+16	April 26, 1 p.m.	L	45
May 1–2	N	—	May 1–2	M	—
May 16, 5 p.m.	E	−16	May 18, 6 p.m.	E	49

From this table some very interesting facts may be gathered. Out of the eleven cases which M. Ricco gives, no less than seven instances occur where the passage of the spots over the central meridian is followed by a terrestrial magnetic disturbance, and not only this, but the magnitudes of both vary directly. The point which the author wishes to emphasize most is the apparent constancy of the interval of time between these two phenomena, and an important fact is that at both appearances of the great February spot the same retardation occurred. In the above table, with the exception of January 29, the mean interval is 45½ kms., "thus indicating a velocity of propagation from the sun to the earth of about 913 kms. per second," or "more than 300 times less than that of light."

New Minor Planets.—Photography seems to be rapidly increasing the number of our minor planets, that is to say, if the announcements really refer to new ones. Wolf and Charlois between them have discovered five this year, the former two (1893 B and C), the latter three (1893, A, D, and E).

The Lunar Surface.—At the present day the general idea with regard to the peculiar features of the moon is that they are the results of stupendous volcanic actions, the number and activity of which surpassed anything that we can imagine. Owing to the extraordinary circularity in the craters, ring plains, walled plains, and to the well-known fact that many of the craters have not the raised lava floor half-way up or near the summit of the cone, which is such a typical terrestrial characteristic, doubt as to their volcanic origin has often been raised. In a small pamphlet which we have received from Mr. S. E. Peal, Sibsagor Assam, the author suggests a "theory of glaciation" in the light of recent discoveries with regard to the maximum surface temperature, and also to the non-viscosity of ice at low temperatures, together with the admitted possibility of snow existing on the moon. The author assumes the moon to be constituted somewhat like our earth, and at one time to have been at a higher temperature, having an atmosphere, water, &c., and draws attention to the facts that there are no polar caps; that colour is conspicuous by its absence, "a feature quite opposed to terrestrial experience, except at the poles," and therefore "may not the entire globe be swathed in snow?"; and the absence of river valleys and drainage sculpturing, indicating that a piling up of dry material has taken place in opposition to a fluvial erosion. At the time when the lunar globe had so far cooled down as to be practically rigid, the tidal action would gradually turn all continents and land surfaces into shoals, and at the temperate stage of development the growth of the polar caps would be restricted to the shallows, extending from them as the temperature became reduced. This advancing sheet of ice would sometimes be deformated by submarine heat vents resulting in a large or small bay, depending on the magnitude of the vent. Extending seawards the "horns of the bay would meet around and enclose this area of higher mean temperature, converting it into a lagoon." Nocturnal radiation and solar heat alternately would perhaps freeze and thaw the ice formed thereon, and with a rare atmosphere and intense cold aqueous vapour would arise from "the water (floe-covered) floor during the day at least, and be carried over the ice edge by diffusion when the fall in temperature would precipitate it into snow, thus gradually forming a vast rampart." Century after century would see the level floor gradually lowered, and the ramparts increased in height. The author accounts for all the peculiar forms of craters, walls, &c., by different local conditions (*i.e.* land or water or submarine vents), but they are all the result "of water floors left in a slowly extending glaciation of the crust."

GEOGRAPHICAL NOTES.

At the French Congress of Learned Societies, which meets on April 4 at the Sorbonne, the section of historical and descriptive geography, is to be devoted specially to the early geographical conditions of France, and to the work of French travellers. The programme includes the consideration of the earliest traces of human habitations, maps of caverns, &c., and proceeds to classify existing dwellings according to their situation and altitude. Local names in danger of falling out of use are to be collected, and the limits of the old districts such as Brie, Beauce, Sologne, &c., to be investigated in order to place on record the geographical conditions which led to their formation.

In the *Scottish Geographical Magazine* for February Mr. J. G. Goodchild gives a most interesting description of a large-scale topographical model of the site of Edinburgh, which he has recently constructed. The model, which is on exhibition in the Museum of Science and Art, Edinburgh, is based upon Bartholomew's map of Edinburgh on the scale of 15 inches to a mile, but the altitudes are taken point by point from the large town plans of the Ordnance Survey. The model is in many ways original in its mode of construction. Its object is purely geographical, having been suggested by a leading citizen as a method of showing the contrast between the circuitous roads and frequent steep gradients of the old coaching days, and the straighter and more level lines of communication by which modern engineers have overcome the restraint of physical configuration.

IN the same number of the *Scottish Geographical Magazine* there is a paper on the Deserts of Atacama and Tarapaca, read to the Society by Mrs. Lilly Grove, and some interesting notes on South Eastern Alaska by Prof. J. J. Stevenson, illustrated by a map.

MR. H. J. MACKINDER's third educational lecture for the Royal Geographical Society was given on Friday night, the subject being the belt of Steppe which traverses Asia from west to east. He showed how the distinctive physical and climatic conditions of the Steppe favoured the growth of nomadic nations, every man of whom was a member of the most mobile cavalry force which ever existed. Pastoral pursuits and marauding were natural to the Steppe peoples, and the descent of their hordes on the settlements bordering the Steppe were turning-points in the history of surrounding nations. Reference to the successive periods of conquest by the Scythians, Huns, Turks, and Mongols showed the power of these nomads on the affairs of other countries, and until the advent of the Steppe-bred Cossacks no western power has ever secured control of the central Asian plains.

FOLLOWING on the death of Captain Stairs we have to record the death of his fellow-officer in the Emin relief expedition, Mr. R. H. Nelson. Mr. Nelson returned to Africa, and was in charge of the district of Kikuyu in Ibea, when he succumbed to an attack of dysentery on December 26, 1892.

THE INSTITUTION OF MECHANICAL ENGINEERS.

THE first general meeting for this year of the Institution of Mechanical Engineers was held on Thursday and Friday evenings of last week, the 2nd and 3rd inst., in the theatre of the Institution of Civil Engineers.

There were two papers set down for reading, as follows:—"Description of the experimental apparatus and shaping machine for ship models at the Admiralty Experimental Works, Haslar," by R. Edmund Froude, of Haslar; "Description of the pumping-engines and water-softening machinery at the Southampton Waterworks," by William Matthews, waterworks engineer.

After the disposal of the usual formal business, the President (Dr. William Anderson) referred to the International Engineering Congress which was to be held in Chicago during the month of August next. He had received a letter from Mr. James Dredge, of London, who had been elected honorary president of the congress. Every one, Dr. Anderson said, knew of Mr. Dredge, so there was no occasion for him to say anything further on that head; but he trusted that English engineers would take steps necessary to a creditable representation.

The next business was an alteration in the bye-laws, the chief referring to the class of membership. Hitherto the institution has consisted of members, associates, and graduates. The two latter classes are, however, of small importance and practically the institution is composed of full members. The qualification for membership was that the candidate should be an engineer not under twenty-four years of age; so that a member might be a Great George Street magnate, or the head of a big engineering firm, down to a draughtsman or the foreman of a machine shop, supposing of course he were an engineer and not simply a mechanic or artisan. These conditions of equality do not appear, however, to meet the views of the council of the institution, so there are to be two classes of engineers on the register, the big and the little. These are to be known respectively as members and associate members, but as far as we can see the broad distinction is that the member has achieved success whilst the associate member has still his way to make. Honour to whom honour is due is a good maxim, but it may be doubted whether the practically self-elected council of an irresponsible body should be the arbiters, not only of fame, but of professional status.

Resolutions embodying the proposed changes were moved from the chair, and carried unanimously. It need not be said that the new rule is not retrospective.

These matters having been settled, the secretary proceeded to read Mr. Froude's paper describing the apparatus in the Haslar establishment, over which he presides. To make clear the details of mechanism given would be quite impossible without the aid of drawings. These were supplied at the meeting in the shape of wall diagrams, but as members had not an opportunity of studying them beforehand, there were very few who were able to keep up with the reading of the paper, excepting those who already knew all about the matter. This is too often—we may say generally—the case in meetings of the technical societies; excepting always the Institution of Civil Engineers. Before this Society a paper is read on one evening, and, if its importance be sufficient, it is discussed during three sittings, each a week apart. Members have therefore an opportunity of grasping the details of the papers read, and preparing what they have to say beforehand. It is for this reason that the discussions before the Civil Engineers have always been instructive.

Mr. Froude's paper deals with but a fragment of its subject, but it takes the part which was more especially of interest to his audience, namely, the mechanical details involved in the apparatus used for testing the models by which a forecast is made of the performance of future naval vessels. It is well known that these forecasts are made possible by the late Mr. Froude's discovery of the law of "corresponding speeds," so that the speed, with a given power, of the full-sized ship can be deduced from the performance of the model. The way in which the late Mr. Froude carried out his investigations, and how the original experimental works grew up at Torquay, under the wise encouragement of the Admiralty, are well known to all interested in physical science. It would be difficult to overestimate the good that has followed this work; for one thing it has done much to put us on an equality with our old rivals, the French—long, indeed, our masters in the science of ship design. Perhaps there is nothing upon which we could better found our claim to naval supremacy—in this long era of naval peace—than the possession of the only naval testing tank of its kind. It is a distinction we shall probably not long be able to boast, for the Russians, Italians, and Americans all contemplate constructing establishments of a like nature.

The paper commences with describing the principal features of the present Admiralty experiment establishment at Haslar. As at the former works at Torquay, the chief object consists of a long covered water-way, in which models of ships are towed to ascertain their resistance. The towing is done from a dynamometer carriage driven at definite speeds by a stationary engine working a wire rope. The models are made of hard paraffine, generally about 14 feet long, and something upwards of 1 inch in thickness as finished. They are cast in a mould with an allowance of about ¼″ for finishing the shape. The latter operation is done by hand, guidance grooves being cut in the model, so that the exact form may be preserved. The working of this shaping or copying machine, and the way in which it enables the lines of a drawing to be translated into model form, constitute one of the most interesting parts of the installation. The water-way, canal, or tank at Haslar is nearly 400 feet long, and of nearly uniform section throughout. The sides are of concrete and vertical, and the railway, on which the dynamometer carriage runs, is bedded on the tops of the side walls of the water-way, in place of being suspended over the water from the roof, as in the original design. The experimental carriage, which has to be nearly 21 feet gauge, is a trussed structure. Its principal peculiarity consists in the fact that the members of the several trusses composing it are wooden trunks or boxes about 4″ square in cross sections, made of ⅜″ deal, and put together with screws and shellac varnish. At the joints formed by the intersection of the various members of the trusses, the sides of the boxes are made to overlap one another over a large area, providing a large surface for screwing and for the adhesion of the shellac varnish. The dimensions of the boxes forming the several members of the girders are designed so as to bring the sides of the boxes into the right planes to suit these overlaps. The whole structure thus provided is remarkably rigid and light. The general design of the carriage is arranged so as to leave clear a sort of central alley provided with a railway, the rails of which are close to the sides of the alley. The object of this secondary railway is to carry the smaller carriages, on which are mounted the actual experimental apparatus of different kinds; so that these may be adjusted on this railway to any desired position fore and aft on the main carriage. The carriage is driven by means of wire rope from a stationary 10″ Tower spherical engine, a high power being required so as to start the truck quickly for high speed experiments. The ordinary speeds range between 100 and 500 feet per minute; for some classes of models experiments are occasionally made up to about 850 feet per minute or nine and a half miles per hour. The truck has been run at over 1200 feet per minute, or about fourteen miles per hour. The governor, by which the speed of the engine is regulated, is a very interesting and ingenious piece of mechanism, which has been modified from the design of that which was used on the engine at Torquay. There are two symmetrical bell-cranks carrying weights, and attached to each other by links, having slotted holes so as to allow the bell-cranks to have a very small range of freedom of angular motion. When a given speed of rotation is reached, the centrifugal force of the weights overcomes the tension of a spiral spring, provided for the purpose, and the governing action is brought into play in the following manner:—There is a hooked rod, by means of which the increase in the angular altitude of the weights (due to centrifugal force) brings a friction disc break into play, which in turn has the effect of extending a spiral spring connected with the engine throttle valve, which is thus closed so as to shut off steam. It will be easily seen how much more delicate an adjustment this device gives than the old Watt governor with the balls acting directly on the valve. The extension of the spring, and the consequent distance of departure of the throttle valve from its full open position are proportional to the frictional turning movement applied to the stationary wheel, which movement is itself proportional to the pressure brought to bear upon it by the bell-cranks; in other words it is proportional to the excess of the speed above that at which the centrifugal force of the weights just equals the tension of the spiral spring. To give greater sensitiveness of action the bell-cranks are not hung on pin joints but on flat springs after the fashion of a clock pendulum, safeguards being provided in case of the springs breaking. With the Torquay governor, which was similar in principle to that described, although differing in appearance, the adjustment was so delicate that a variation of speed in the running of the carriage of half a foot per minute was seldom exceeded even at the highest speeds. The value of working against the resistance of spiral springs will be noticed in this mechanism, their steadying action being especially valuable. It would be impossible for us to attempt to describe the mechanism constituting the copying apparatus of the model shaping machine, and we can only hope to give a mere outline of the general principles. A rough hollow model of the ship to be constructed is cast in paraffine wax, a material which is found to lend itself most perfectly to the necessities of the experiments. The drawing from which the operator has to work is stretched on a table, and the grooves representing the water lines are copied from the drawing by means of the mechanism. These grooves are formed by a pair of revolving cutters, the fore and aft motion being communicated to the model whilst the cutters move laterally. One cutter is on each side—for of course full models are required—and they approach or recede symmetrically in such accordance with the longitudinal travel of the model as to trace in plan upon it the intended horizontal section. This due accordance of the lateral motion of the cutters with the longitudinal motion of the model is accomplished by the operator so regulating the cutter motion as to maintain a tracer in contact with the corresponding water-line on the drawing. By suitable mechanism the drawing itself is made to imitate the longitudinal travel of the model, while the tracer imitates the lateral travel of the cutters. In the Torquay machine the tracer was guided by an adjustable template set to the curve of each water-line, but afterwards the tracer was made to follow the line on the drawing by the operator. In the present machine the cutters are raised or lowered to get the different water-lines. The cutters run at 2700 revolutions per minute. The grooves having been cut, the surplus material is removed by hand.

We shall not follow Mr. Froude in his description of the further details of the mechanism, as it would be unintelligible without the drawings by which he illustrated his description. The various arrangements are, however, fully worthy of study by all who are interested in ingenious mechanical devices; but we must refer our readers to the printed transactions of the institution, in which the diagrams will appear when the volume is published. There is also a weighing machine, which is necessary to obtain the actual dead weight of the model, so that the amount of ballast required to get the necessary displacement corresponding to trial draught may be determined. This machine will weigh up to 1000 lbs. with great accuracy, and is similar in principle to an ordinary chemical balance, except that it is a steel yard, having one arm 6 inches and the other 5 feet in length.

The discussion on this paper was opened by Mr. W. H. White, the Director of Naval Construction, who is the official head of the Admiralty department, of which the Haslar establishment forms a branch. Mr. White spoke of the advantage these model experiments had been to the navy, saying that the great advance in the speed of ships which had been obtained of late years would not have been reached to the full extent had it not been for the model experiments carried out at Torquay and Haslar by the late Mr. Froude and his son, the author of the paper. Mr. J. I. Thornycroft also pointed out the great economy that had been made in expenditure upon navy ships by finding out beforehand what the proposed vessel would do, and what was required in the way of power to reach that performance. Mr. Thornycroft made especial reference to the ingenuity of the device whereby a line on the drawing, which might not be quite accurate, would be made to give the desired result in the model, and this without an expensively-constructed apparatus. Various other speakers having been heard, and Mr. Froude having briefly replied, so far as there was anything to reply to, the meeting adjourned until the next evening.

On the members assembling on Friday evening, the 3rd inst., the president, Dr. Anderson, again occupied the chair, and Mr. Matthews's paper on the Southampton waterworks was read. This contribution is interesting, as it describes what we understand is the largest water-softening plant yet installed. The quantity of water that can be satisfactorily dealt with is from $2\frac{1}{4}$ to $2\frac{1}{2}$ million gallons per day of 24 hours. Of course the principle of softening hard water by lime is very far from new, but it has made slow progress, in spite of the vast quantities of hard water, otherwise unobjectionable, that there are in the chalky southern half of our island. This limited application of a means whereby a bad water in one respect can be made a good one in all respects does not appear, to judge by the proceedings of last Friday, to spring from any inherent defect in the system—beyond that which would arise from the disposal of the refuse lime in crowded cities—but rather from the carelessness of public authorities and water-supplying companies to the wants and comforts of the people at large.

The meeting terminated with the usual votes of thanks, the President announcing that the summer meeting would be held this year at Middlesborough on Tuesday, August 1, and the following days.

THE SEVEN IMAGES OF THE HUMAN EYE.

IT is well known that in the human eye, besides the refracted image, which serves the purposes of vision, there are formed three reflected images known under the name of "Purkinje's images." M. Tcherning has discovered three additional ones, so that the total number is brought up to seven.[1]

In its passage into the interior of the eye each ray of light has to pass through the cornea, the aqueous humour, the crystalline lens, and the vitreous humour before finally arriving at the retina. At the surface of each of these constituents the ray is liable to be partially reflected, thus giving rise to four reflected images. These were all seen and described by Purkinje at the beginning of the century, but only three were observed by Helmholtz and others. These three can be easily observed by two persons on holding a lighted match between their eyes, and moving it about so that the reflections seem to come from the pupil. One of them, that reflected by the front of the cornea, is much brighter than the two others, which are formed by the front surfaces of the crystalline and the vitreous humour respectively. The fourth image is due to reflection from the posterior surface of the cornea. It may be discovered by careful observation of the brightest image by means of a magnifying glass. As it approaches the border of the pupil, and especially as it passes on to the iris, it is seen to be accompanied by a small, pale, but well-defined image, which always lies between the first image and the centre of the pupil, the distance between them decreasing as they move towards the centre, where they finally coincide. By means of the ophthalmophakometer—an instrument consisting of three incandescent lamps and a telescope arranged on an arc of 86 cm. radius—it was found possible to measure the radii of curvature of all the reflecting surfaces. The foci of the two reflecting surfaces of the cornea were found to coincide, a fact which accounts for the coincidence of the two corresponding images at the centre of the pupil, and for Helmholtz's failure of finding the fainter one.

---

[1] See *Séances de la Société Française de Physique*, Avril-Novembre, 1892.

It is evident that since the light reflected from the successive surfaces does not fall upon the retina, it is lost for visual purposes. But a comparison of the percentages of loss in the case of the eye, and in that of a simple lens tells greatly in favour of the former as an optical instrument. In the eye the percentage of useful light is 97, in a simple lens 92, and in a compound optical instrument correspondingly less. But the light reflected by any of the internal surfaces is also liable to be reflected back into the eye or the optical instrument, with the effect of superimposing a more or less faint patch of light upon the image on the retina. This is termed the noxious light (*lumière nuisible*) by M. Tcherning. In a simple lens this amounts to ⅛ per cent., whilst in the eye it is as low as 0·002 per cent. But faint as it is, it is capable of giving rise to two light impressions due to double reflection, one at least of which has been actually observed in the human eye. "The easiest way of observing it," says M. Tcherning, "is to look straight forwards in a dark room, holding a lighted candle in the hand about 20 cm. from the line of vision. On moving the candle gently from side to side a pale image of the flame is seen on the opposite side of the line of vision, distinct enough to show that it is inverted; it moves symmetrically to the candle with respect to the line of vision. The rays which form this image have undergone, besides several refractions, two reflections, one at the posterior surface of the crystalline and another at the front surface of the cornea." Another image was expected to be formed by a similar reflection at the anterior surface of the crystalline. It was found in an artificial eye, but not in the human sense-organ. However, an easy calculation of the optical system of the eye explains this circumstance. The focus of the reflected rays is very near the crystalline lens itself, so that they must be much dispersed by the time they reach the retina. To enable the image to be formed on the retina, the object would have to lie between the cornea and the crystalline, but on attempting to form a luminous point at that place by optical means it is found that the "useful rays" fill the eye to such an extent as to render everything else invisible.

It is found that different eyes differ in their capacity of seeing the first of the two additional subjective images. Short-sighted people find it very indistinct unless the candle is held close to the eye, or convex glasses are used. As the maker of optical instruments utilises the accessory images for testing the degree of polish and the accurate centreing of the lenses, so the physician is enabled to make valuable inferences from them as to the structure and condition of the eye he is examining, and the additional images discovered by M. Tcherning appear to be of considerable physiological importance. E. E. F. d'A.

A BOTANIST'S VACATION IN THE HAWAIIAN ISLANDS.

SOME weeks ago we reprinted from the *Botanical Gazette* (Indiana) a part of the first instalment of Prof. D. H. Campbell's interesting account of his vacation in the Hawaiian Islands. The following is the chief portion of the second and concluding instalment, published in the January number:—

Beside visiting the isle of Oahu, I made short trips to the islands of Hawaii and Kauai. The former, the largest of the group, and the only one where volcanic action is still going on, is reached by steamer in about thirty-six hours from Honolulu. On the way, the islands of Molokai, Lanai, and Maui are passed. The first, a barren-looking and forbidding spot, is the location of the leper settlement, to which all persons afflicted with leprosy are sent as soon as their condition becomes known.

Maui, the largest of the islands next to Hawaii, consists of two portions connected by a narrow isthmus. The whole eastern half is nothing more nor less than the body of an immense extinct volcano, ten thousand feet high, and with a crater nearly ten miles across. The other end of the island is an older formation. This island is said to be very interesting botanically; but, unfortunately, my time did not permit me to visit it.

Very soon after sighting Maui, the three great mountain masses of Hawaii began to loom up. The day was clear, and the whole formation of the island became visible. It consists of three great volcanic cones, of which only one is now active. The highest summit, Mauna Kea, is nearly 14,000 feet above the level of the sea; the next, Mauna Loa, lacks but a few hundred feet of this; yet so great is the breadth of these masses that one fails to realise their immense height. Our first landing was at Mahukona, on the leeward side of the island, a most forlorn expanse of bare lava with scarcely a trace of vegetation, except a few unhappy-looking algaroba trees planted about the straggling buildings that constituted the hamlet.

We lay all day at this inhospitable station, not getting away until evening. A beautiful sunset and a fine glimpse of the peak of Mauna Kea glowing with the last rays of the sun, form my most pleasant recollections of this desolate place.

What a change the next morning! On awakening we found ourselves entering the harbour of Hilo. Here everything is as green as can be imagined, and luxuriant vegetation comes down to the very ocean's edge. The town is built on a bay fringed with cocoa-nut trees and embowered in a wealth of tropical vegetation. Owing to the great annual rainfall (about 180 inches), as well as to the fact that Hawaii is the most southerly of the islands, the vegetation here is the most luxuriant and tropical found in the whole group. I remained in Hilo for six days and collected some most interesting specimens. Through the kindness of Mr. Hitchcock of Hilo, I was enabled to spend the night at his camp in the woods near the town, and the greater part of two days collecting in the vicinity. The forest here is most interesting. Mr. Hitchcock was starting a coffee plantation and has cut trails through the woods in several directions, so that collecting was very convenient. There is great danger of losing one's self in these woods where there are no trails, as much of the forest is an almost impassable jungle. In these moist forests ferns and mosses luxuriate, and every trunk and log is closely draped with those beautiful growths. Flowers are almost entirely wanting, a fact repeatedly observed by collectors in tropical forests. I saw here fully developed specimens of tree-ferns. The finest of these were species of Cibotium. Many had trunks from fifteen to twenty feet high, and some must have been fully thirty. The most beautiful were some with trunks ten to fifteen feet high, as these were more symmetrical and had finer fronds than the taller ones. I measured the leaves of one that had fallen over, and roughly estimated the length as eighteen feet. I have no doubt that specimens fully twenty feet long could be found. These giant fronds, arching high over one's head as one rides on horseback under them, present a sight at once unique and beautiful. Growing upon the trunks of these ferns were many epiphytic species, the most peculiar of which was *Ophioglossum pendulum*, with long strap-shaped leaves, a foot or two long, and a spike of sporangia sometimes six inches long. Exquisite species of Hymenophyllum and Trichomanes, the most ethereal of all the fern tribes, with almost transparent, filmy leaves, were common, sometimes completely enveloping the trunks of the trees. Of the terrestrial ferns, which abounded everywhere, two were especially notable as representing groups unknown in the United States. One of these, *Gleichenia dichotoma*, forms extensive thickets on the borders of the forest, and in the Hilo district extends down almost to the sea-level. The other, *Marattia Douglasii*, a very large fern with leaves eight to ten feet long in well-grown specimens, has fleshy dark green leaves, and thick stipules sheathing the base of the leaf-stalks. Several species of Lycopodium and Selaginella were common, and a good variety of mosses and liverworts. In these forests wild bananas are common, and most magnificent plants they are. Sheltered from the wind, the superb great leaves develop to their full size, without being torn in the least, and the whole plant is a study of beautiful form and colour.

Coffee is being extensively planted in this region as well as upon the lee side of the island, and as the quality of the berry is exceptionally fine, this promises soon to be a leading industry in the islands.

About Hilo especially, but common also elsewhere, was a very conspicuous black fungus, that covered the leaves completely in many cases, and attacked indiscriminately a great variety of trees.

From Hilo I proceeded to the volcano of Kilauea, some thirty miles distant, and about 4000 feet above the level of the sea. As this volcano has so often been the theme of travellers' descriptions I will not linger over it. In the vicinity are many interesting plants, among them a species of Vaccinium with sub-acid yellow and red berries something like cranberries. These "ohelo" berries are much esteemed, and are especially good when cooked. Some two miles from the volcano is a superb grove of koa trees, the largest trees I saw anywhere in the islands. One of these standing alone, and with magnificent spread of branches, must have been ten feet in diameter. The road to the volcano lies for much of the way through a fine forest. In the lower part the ohia trees were loaded with their beautiful crimson fruit, and present a very showy appearance. Of flowers, the species of Ipomæa were the most conspicuous; but the scarlet flower-bracts of Freycinetia were conspicuous at times, for here this latter plant may often be seen running to the tops of the tallest trees.

The glory of this road, however, is the tree-ferns, which all along excite one's admiration. The carriage road is not yet completed, and about thirteen miles must be done on horseback. Of this more than a mile is over a corduroy road made out of the trunks of ferns! Such a road, if not very durable, is yet very pleasant to horses. As these trunks lay prostrate, in the damp atmosphere, most of them were already sending out new fronds, and in due course of time the road will be fringed with a hedge of great fern-leaves. Indeed, in some of the more open parts of the road farther down, where the ground is completely occupied by a small tree-fern growing in dense thickets, as these are grubbed out to make way for cultivation, their trunks are piled up to form fences, and soon sprout out so that they make a beautiful and close hedge of fern-leaves.

On leaving the volcano I went down on the other side of the island. The rain being almost entirely intercepted by the mountains, this leeward side is very dry, and the ride to Punaluu, where we were to take the steamer, was not especially pleasant. Vegetation is very scanty, and nothing particularly interesting was noted in this line. The soil on this side of the island, especially in the district of Kona, is very fertile, and when water can be had, produces magnificent crops of all the tropical staples, pine-apples, cocoa nuts, coffee, sugar, &c., all especially fine; and we feasted on these cocoa-nuts and pine-apples as we sailed along this picturesque, if somewhat barren, coast.

A short, flying trip was made to the Island of Kauai, the richest botanically of all the islands, as it is the oldest geologically. According to Hillebrand, not only is the number of species larger than in the other islands, but the species are more specialised. Here I saw several species of the curious woody Lobeliaceæ, of which there are several genera that form either shrubs or small trees. I saw several species of Cyanea, with stems six to eight feet high, with long leaves crowded at the top of the stem and many white or purplish flowers, much like those of Lobelia, but somewhat larger and less open.

As in all the islands, there is on Kauai a great difference between the windward and leeward sides. I drove for about thirty miles along the windward side of this island through some of the most beautiful scenery of all the islands. Near the sea were rolling plains and hills, with here and there groves of Pandanus and Hau—the latter a dense spreading small tree with large yellow hibiscus-flowers—and at one point we drove through a magnificent grove of kukui trees, the finest I saw anywhere. As we reached that part of the island which is most fully exposed to the moisture-laden trade-winds, vegetation became extremely luxuriant. Numerous valleys with clear streams flowing down them, their bottoms given up to rice plantations, were to be seen here, with the rice in all stages, from the young spears just standing above the water to golden-yellow patches of ripe grain. At Hanalei, my destination, I found excellent accommodation and a delightful bathing beach, the latter especially attractive after a thirty-five mile drive over dusty roads. Hanalei is beautifully situated on a picturesque bay, with bold mountains rising directly back. The next morning a native was hired to go with me into the woods, and the day was spent in collecting. The variety of trees, as well as other phænogams, is much greater here than in Hawaii; the ferns, also, were very fine. Here I obtained a prize in a fine lot of the prothallia and young plants of Marattia, as well as some other interesting things.

Want of space forbids going into details, but no botanist visiting the islands can afford to miss Kauai.

In position, the Hawaiian Islands are unique, being more isolated than any other land of equal area upon the globe. More than 2000 miles separates them from the mainland, and 1860 miles from the nearest high islands. Of purely volcanic origin, thrown up from an immense depth, they have always been thus isolated. As might be expected, the flora is very peculiar, more so than in any other country. According to Hillebrand, of 800 species of spermaphytes and pteridophytes that are strictly indigenous, 653, or 75 per cent., are endemic. Taking out the pteridophytes, the spermaphytes show over 81 per cent.; and the dicotyledons over 85 per cent. that are found only in this group.

For a thorough study of this very curious flora, a long time would be necessary, as many species are extraordinarily local, and many of the most interesting localities are very difficult of access. The islands differ extremely among themselves, and exhibit in a most interesting manner the correspondence that exists between the variety and differentiation of forms and the ages of the islands. The formation of the islands has proceeded from north to south; and Kauai, the northernmost of the large islands of the group, is also the oldest and much the richest botanically, especially as regards spermaphytes; and, according to Hillebrand, the genera and species are more differentiated. Hawaii, the southernmost of the islands, is much the poorest in forms, although in the Hilo district the conditions are most favourable for a luxuriant development of forms.

In the latter island is the last active volcano of the group, Mauna Loa, with its two craters, of which the well-known crater of Kilauea is the great sight of the islands, and visited constantly by tourists from all parts of the world.

A few days after my return to Honolulu from Kauai, and six weeks from my first arrival there, I boarded the *Monowai*, the through Australian steamer bound for San Francisco, which was reached in due season after an uneventful passage. And so ended my first trip to the tropics.

INSTRUMENTS FOR THE EARTHQUAKE LABORATORY AT THE CHICAGO EXPOSITION.

THE first earthquake instrument ever invented, a drawing of which is shown on the wall, is in all probability that of Chōkô, dating from the year A.D. 132. The first instrument used for keeping systematic records in Japan was Palmieri's modification of the contrivance sketched out by the late Robert Mallet. Since this not only have all forms of seismographs and seismoscopes employed in Europe and America been employed, but many special forms have been designed in Japan, with the result that rather than Japan borrowing from Europe and America, these countries are using inventions which had their origin in Japan. A few of these instruments are exhibited in this laboratory. The main feature in their construction is that they all work from "*steady points*," and for small earthquakes at least, we can say with confidence that the diagrams they yield are absolute measurements of the earth's motion. From diagrams written on stationary plates we know the extent and the direction of the principal vibrations in a shock, but when the movements are recorded on a moving surface, we know the period or the rapidity with which the movements follow each other. From these latter diagrams the acceleration or suddenness of movements may be calculated, and the factors given to engineers enabling them to construct to resist known forces, rather than simply building strongly because an earthquake is strong.

INSTRUMENTS EXHIBITED.

1. *Seismograph writing on a glass disc.*—Here we have horizontal pendulums writing the earth's motion as two rectangular components on the surface of a smoked glass plate. The vertical motion is given by a vertical spring lever seismograph. The rate at which the plate revolves is accurately marked by an electrical time ticker. The movements of the latter are governed by a pendulum swinging across and making contacts with a small vessel of mercury.

The revolving plate is kept in motion by clockwork, which is set in motion by an electric seismoscope. (See No. 8.)

2. *Seismograph writing on a drum.*—In this instrument the record is written on a band of paper, the diagram being less difficult to interpret because it is written to the right and left of a straight line and not round a circle.

3. *Seismograph writing on a band of paper.*—In this instrument not only is the diagram written along a straight line but it is written with pencil,—the trouble of handling smoked paper being therefore avoided. When the earthquake ceases, the drum ceases to revolve, but if a second or third earthquake should occur, it is again set in motion. By this means a series of earthquakes may be recorded, the resetting of the instrument being automatic.

4. *Seismograph without multiplying levers.*—This instrument is intended to record large motions, the horizontal levers not being prolonged beyond the steady points to multiply the motion. For large earthquakes, when the ground is thrown into wave-like undulations, special instruments which measure tilting are employed.

5. *Duplex pendulum seismograph.*—In this case a steady point is obtained by controlling the motion of an ordinary pendulum with an inverted pendulum. The record consists of a series of superimposed curves written on a smoked glass plate.

6. *Mantelpiece seismometer.*—This is intended for the use of those who simply wish to know the direction and extent of motion as recorded at their own house. It is a form of duplex pendulum, and it gives absolute measurements for small displacements.

7. *Tromometer.*—This is one form of an instrument which is used to record movements which are common to all countries, called earth tremors. Every five minutes, by clockwork contacts and an induction coil, sparks are discharged from the end of the long pointer to perforate the bands of paper which are slowly moving across the brass table. If the pointer is at rest, then a series of holes are made following each other in a straight line, but if it is moving, the bands of paper are perforated in all directions round what would be the normal line of perforations.

The earth movements which cause these disturbances are apparently long surface undulations of the earth's crust, in form not unlike the swell upon the ocean.

A more satisfactory method of recording these motions, which has been used for the last two years, is by a continuous photograph of a ray of light reflected from a small mirror attached to a small but extremely light horizontal pendulum.

8. *Electrical contact maker.*—These instruments are delicate seismoscopes, which on the slightest disturbance close an electric circuit, which, actuating electric magnets, set free the machinery driving the recording surfaces on which diagrams are written.

9. *Clock.*—At the time of an earthquake the dial of this clock moves quickly back and forth and receives on its surface three dots from the inkpads on its fingers. It thus records hours, minutes, and seconds, without being stopped.

10. *Model of an earthquake.*—The bent wires represent the path traced by an earth particle at the time of the earthquake of January 15, 1887. The numbers indicate successive seconds. This model was made by Prof. S. Sekiya.

11. *Safety lamps.*—These are lamps which if overturned are at once extinguished. One of these is a European invention and the other Japanese.

12. *Pictures.*—The pictures on the walls show the effects of the Great Earthquake of October 28, 1891, the devastation following the Eruption of Bandaisan in 1887, and several of the more important volcanoes in Japan. They were made by Prof. W. K. Burton.

JOHN MILNE, F. ŌMORI.

Seismological Laboratory, Imperial University of Japan,
Tokio.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—Last Term the Board of Faculty of Natural Science recommended that an honour examination in Natural Science should be instituted, bearing the same relation to the Final School that Moderations bear to the Final School of Literae Humaniores. The recommendation of the Board was not unanimous, and on the matter coming before the Hebdomadal Council last week, it was put aside on the ground of want of unanimity among the various scientific departments. There was much to be said both for and against the proposed examination. It would probably have raised the standard of the chemical and physical work done by biologists, but would have forced an additional subject on the chemists and physicists, which they were very unwilling to assent to.

CAMBRIDGE.—The Adams Prize has been awarded to Prof. J. H. Poynting, F.R.S., late Fellow of Trinity College, for a memoir on the methods of determining the absolute and relative value of gravitation and the mean density of the earth.

The Professor of Pathology (Mr. Roy) gives notice that on Thursday, February 9, a lecture and demonstration will be given by Dr. Hafkine, of the Pasteur Institute, on his method of conferring immunity against Asiatic cholera. The lecture will be delivered at the Pathological Laboratory at 4.30, and will be open to members of the University.

The office of Esquire Bedell has been rendered vacant by the death of Mr. F. C. Wace, a distinguished mathematician, formerly Fellow and Lecturer in Mathematics at St. John's College, and thrice elected Mayor of the Borough of Cambridge.

SCIENTIFIC SERIALS.

Wiedemann's Annalen der Physik und Chemie, No. 1.—Essay towards an extension of Maxwell's Theory, by Hermann Ebert. The author obtains expressions for dispersion and absorption of waves of the order of light-waves analogous to those obtained by Goldhammer, and shows that they may be derived from Maxwell's fundamental conceptions by applying them to the case of rapidly changing displacements.—A new kind of magnetic and electric measuring apparatus, by G. Quincke. These are made of glass, ebonite, and wood. No screws are used in their construction, and they are claimed to cost a tenth of the price of ordinary instruments, with equal accuracy. In each of them the needles are suspended at the hollow centre of a vertical circular glass disc.—On a null method for measuring the dielectric constants of conducting liquids, by Friedrich Heerwagen.—On a phenomenon analogous to Newton's rings observed during the passage of Hertz electric plane waves through plane-parallel metal plates, by Ludwig Boltzmann. The author removes an apparent contradiction between Maxwell's theory and Hertz's observation that even excessively thin metal plates do not transmit electric waves a few decimetres long, by showing that this is not due to absorption, but to the limiting conditions at the surfaces of separation deducible from Maxwell's formulæ.—On a medium whose mechanical properties lead to the equations propounded by Maxwell for electromagnetism, by L. Boltzmann.—On some questions concerning Maxwell's theory of electricity, by L. Boltzmann.—The index of refraction of electric rays in alcohol, by H. O. G. Ellinger.—On the electrification of air in glow and brush discharges, by Ad. Heydweiler.—On the calculation of magneto optic phenomena, by P. Drude.—Spectra of aluminium, indium, and thallium, by H. Kayser and C. Runge.—On the infra-red spectra of the alkalies, by H. Kayser and C. Runge. A criticism of Benjamin Snow's work on the same subject.—Investigations concerning interior conduction of heat, by Richard Wachsmuth.—On the absolute value of the thermal conductivity of air, by A. Winkelmann.—On a modification of the transpiration method suitable for the investigation of very viscous liquids, by C. Brodmann. The substance was made to pass from a funnel-shaped reservoir through a capillary tube into a beaker standing on one pan of a chemical balance. The time was noted at which the amount of liquid passed into the beaker was large enough to overcome the counterpoise in the other pan, and to disturb the equilibrium, and further small weights were added and similarly dealt with. The temperature was kept constant by a spiral water-pipe and felt jacket, and local differences and variations of level and buoyancy were corrected for. The liquid experimented upon was glycerine, and the temperature curves were hyperbolas.—Notes on M. Cantor's thesis on capillary constants, by Th. Lohnstein.—Note on the purification of mercury, by W. Jaeger.

Notes from the Leyden Museum.—Of volume xiv. numbers 1 and 2 were published in April, and numbers 3 and 4 in July last. Edited by Dr. F. A. Jentink, this volume contains 282 pages and ten plates. The notes on Mammals are; by the editor on *Semnopithecus pyrrhus*, Horsfield; and on *Pithecir melanurus*, S. Muller (Pls. 3 and 4). In volume xii. Dr. Jentink,

p. 222, gave a note about this latter very rare, nearly forgotten, and often misunderstood little rodent, figured by Alfred Duvaucel in F. Cuvier's great work, the "Histoire Naturelle des Mammifères." Cuvier could give no indication of its size, nor of its native country, guessing that "qu'il est originaire des provinces du Nord de Bengale, si ce n'est des parties occidentales de Sumatra." Dr. S. Müller, in 1834, obtained a specimen in Java, to the northern side of Mount Gede, and named the species. This, and another specimen from Sumatra (also collected by Müller) are both in the Leyden Museum as stuffed specimens. The skulls of these two specimens were detected in the Leyden Museum by Oldfield Thomas, and were included by Jentink in his catalogue of 1887, though with a query. But all doubt on the subject was removed at the date of this paper; and now the animal has been taken alive by Mr. J. D. Pasteur on the northern slope of the Goenong Gedeh, Java, an account of which capture is given in a very graphic translation of a letter to Dr. Jentink. On birds there are papers by J. Büttikofer on the specimens of the genus Tatare in the Museum, on the specific value of Levaillant's "Traquet Commandeur," and on the collections of birds sent by the late A. T. Demery from the Sulymah river, West Africa, pp. 13–30. In this last paper 96 species are recorded, ten of which are new to Liberia; on *Batrachostomus poliolophus*, n. sp. from W. Sumatra, by Ernst Hartert; on a weaver finch from Sumatra; and on a collection of birds from the islands of Flores, Sumba, and Rotti, by J. Büttikofer; and on the birds of Sumba, by A. B. Meyer. About fish there is a note by Dr. Th. W. van Lidth de Jeude on *Orthragoriscus nasus*, Ranzani, which had been washed ashore in November, 1891, at Callantsoog. A figure from a photograph is given.—M. Schepman describes a number of land and fresh water mollusca from Soemba, Timor, and other East Indian islands; several new species are diagnosed.—Dr. J. G. de Man continues his Carcinological studies in the Leyden Museum, and in No. 6 describes several new species which are figured. A very important contribution to our knowledge of the echinoderms is made by Dr. Clemens Hartlaub's paper on the species and structure of the hard parts in Culcita; nine species are carefully described, their geographical distribution is given, *Culcita grex*, M.T., is figured from a photograph, and a fairly complete bibliography is appended. The rest of the papers are descriptions of new forms of insects.

No. 1 of vol. xv., dated as January, 1893, but published October 30 last, contains a review of the genus Rhipidura, with an enumeration of the specimens in the Leyden Museum. A key to the 75 species now known is given—five are described for the first time. M. E. Buchner has a note on the occurrence of *Mellivora indica*, Kerr, in the Trans-Caspian district; on two supposed new species of Pentadactylus, by M. Schepman. There are also several papers on new forms of insects.

SOCIETIES AND ACADEMIES.

London.

Royal Society, January 26.—"On the Three-Bar Motion of Watt." By William Brennand. Communicated by C. B. Clarke, F.R.S.

"Further Researches in Connection with the Metallurgy of Bismuth." By Edward Matthey, F.S.A., F.C.S., Assoc. Roy. Sch. Mines. Communicated by Sir G. G. Stokes, Bart., F.R.S.

Paper IV.—"Bismuth, its Separation from Arsenic."—In melting large quantities of bismuth containing arsenic it was found that the surface of the metal being exposed to the air arsenical fumes appeared, and that as the temperature of the metal was raised the arsenic came off in dense white fumes (As_2O_3). An alloy of bismuth containing 0·65 per cent. of arsenic was carefully operated upon and freed from the whole of its arsenical contents, the temperatures being noted at which the separation takes place. When raised to a temperature of 513°C. and maintained at this for a short period, the bismuth was found to be absolutely free from arsenic.

Paper V. "Bismuth, its Separation from Antimony."—Whilst engaged in fusing some 400 or 500 kilogrammes of bismuth containing antimony it was noticed that a peculiar oily film formed on the surface of the alloy, which on being removed and tested was found to contain a considerable percentage of antimony. By continuing the operation and removing the film from time to time as it formed, the melted metal became bright, and was then found to be perfectly free from antimony. A quantity of about 350 kilogrammes of bismuth containing 0·80 per cent. of antimony was melted and the temperature observed at which the antimony separated as described. By maintaining a constant temperature of 458° C. the whole of the antimony separated, leaving the bismuth free from any trace of this metal. The temperatures were determined by the pyrometer of M. H. le Chatelier.

Physical Society, January 13.—Prof. G. F. Fitzgerald, F.R.S., President, in the chair.—Mr. F. W. Sanderson read a paper on science teaching. In this communication the author considers the methods of teaching physical science, and remarks that other sciences may best be treated in some different manner. The method recommended is one found suitable in public schools where boys may remain till about the age of nineteen. In elementary and secondary schools modification would be necessary with a view to making it more immediately useful, whilst in university and technical colleges other methods might be preferable. The object of his public school method was to make physical science a definite means of education, rather than to produce skilled physicists. Certain mathematical subjects, such as arithmetic, geometry, and algebra, should be taught before physics is begun, and taught in such a way as to aid subsequent physical work. In teaching arithmetic it is deemed desirable to distinguish between the science and the art of it, and to have separate hours for instruction in each. The subjects included in each part are described in some detail in the paper. No existing arithmetic satisfies the author's requirements. Geometry is considered of the first importance; practical geometry and the use of instruments forming the best introduction to the subject. It is recommended that the elementary part be taught by the mathematical master with a view to formal geometry, *e.g.* Euclid. As most practical geometries consist of isolated constructions they are useless for teaching the subject in a scientific manner. A number of problems suitable for a graduated introductory course are given. After elementary geometry, mensuration may be taken up with advantage, the facts being verified by drawing to scale, measuring, or by weighing, but no rules being given. Trigonometry of one angle may then be commenced. Here also free use should be made of the drawing board, each pupil finding the sines, cosines, and tangents of angles by drawing and measurement, and making tables. Quite independent of the mathematical class the author has been in the habit of carrying boys on the engineering side through a course of graphical analytical geometry, in which they draw straight lines and the quadratic curves, &c., from their equations, solve simultaneous linear equations, quadratics, cubics, &c. Other geometrical constructions follow. The subject as to what branches of science should be taught in the different departments of a school is then considered, and schemes are given for the classical, modern and commercial, science, and engineering sides. Some general principles which have been kept in view in arranging the physical teaching are next described. In the first place the fundamental experiments and observations on which each scientific law is based are explained to the pupils, and when possible the experiments are performed by the boys in the laboratory. Secondly, from the experiments the laws are stated as precisely as possible, the form of statement depending on the knowledge possessed by the class. The problem of expressing a law mathematically from its most fundamental statement is then fully considered. Thirdly, mathematical deductions from the laws are followed out, and the pupils perform experiments to verify the results, and thus confirm the laws. Fourthly, a course of exact physical measurements is given, which includes mensuration, hydrostatics, mechanics, sound, heat, electricity, and light. A first and second year's course is arranged in each subject, and in both years all the boys work the same experiment at the same time. This necessitates multiplication of apparatus, but being of a simple character in the lower forms where the pupils are numerous it is not prohibitive. It is also stated that boys get better results with comparatively rough apparatus, if large, than with delicate and expensive instruments. About half the time devoted to physics is spent in the laboratory. Mathematics is introduced, as far as can be done without straining the pupils too much, and with young classes appeal is made to experiment where the strictly logical argument would be difficult to follow. Instead of teaching the applications of science as done in some technical schools, the author's method is to teach pure science, and let the applications come in as illustrations. At the end of the paper detailed lists of experiments for practical courses in electricity and optics are given. Samples of the apparatus used were exhibited at the meeting, those for optics being particularly simple and ingenious.—Prof. A. M. Worthington said his experience led him to a very hearty agreement with Mr. Sanderson on all essential points, and he thought there was now a close agreement amongst teachers as to the best methods. He therefore wished to ask, Had not the time now come at which the Physical Society might usefully endeavour to exert direct influence on science teaching? As the scientific instruction of a person who intends following a scientific calling is generally divided into stages, and conducted in different places under different teachers, he thought it was desirable that those in charge of his training at each stage should say up to what point his instruction should be carried before he reaches them. Other matters in which the society might do useful work were (1) reporting on text-books and condemning the bad ones, and (2) furthering the adoption of the decimal system. At present, he said, an enormous extension in the teaching of physical science is taking place, and it seemed within the power of the Physical Society to place itself at the head of the movement. Another point which required to be settled was the relative importance of physics and chemistry at different stages of a student's education.—Mr. L. Cumming agreed with the general principles laid down by Mr. Sanderson. In attempting to carry out such schemes numerous difficulties presented themselves, especially where the science master had not control over the subdivision of the boys' time. He had tried teaching the science of arithmetic to boys in the lower forms, but the results were not encouraging, for he found very few who could do much in it. They seemed to devote themselves much more readily to concrete problems and the art of manipulation of rules. Graphical statics was very valuable. As regards experimental lectures, he believed them to be very important, especially in junior classes. For scholarship boys a different method had been tried with success. Instead of performing lengthy experiments completely before the class, the essential parts were gone over, and for the minor points the results obtained in experiments made before or after the lecture were given, so that all the data for reducing the results were to hand. This saved considerable time. He had hoped Mr. Sanderson would say something about the slide rule, and wished to learn his opinions on its use.—Dr. Stoney said he was very much struck with the methods of teaching brought forward by Mr. Sanderson, and remarked that his own work would have been considerably lightened if such a scheme had been developed many years ago. Experimental methods were very valuable, provided the inaccuracies of measurement be kept in view. Plotting curves was also very instructive, and might be made a means of furnishing the fundamental notions in the differential and integral calculus. As to the introduction of chemistry, his experience went to show that this should be done at an early age. Dynamics should also be begun early.—Mr. W. B. Croft thought that if the Society did make rules to regulate the teaching of physical science, these rules should not be too strict, for the ages and aims of boys might differ widely. At Winchester the science teaching was carried out on the lines recommended by a committee of the Royal Society appointed to consider the subject. (Leaflets showing the scheme adopted were here distributed to members.) The object of the scheme was not merely to make science a means of education, but an integral part of the education of the pupils. He also made a point of keeping the lecture experiments up to date.—Mr. Rentoul said dynamics should not be taught as a mathematical subject, but experimentally. He thought it of the first importance that boys should learn how to find out facts for themselves, and for this practical work was essential.—Prof. Ayrton remarked that the conditions under which science was taught differed in different places. He himself taught with the object of enabling the persons under instruction to improve the industry. For this purpose he believed the analytical method more suitable than the synthetical one advocated by Mr. Sanderson. It also had the advantage of being more scientific, for it was more natural, being, in fact, that used by children from birth, for they had no other means of learning the nature and properties of their surroundings. In his first year's technical course the work was synthetical, whilst in the third year the students, having analysed existing apparatus, were taught to devise new or improved forms, and hence the work became more synthetical.—Mr. F. J. Smith said it was important that students be taught to measure by the balance, micrometer, spherometer, and as soon as possible. He also inquired how far Mr. Sanderson's pupils could help themselves in making the apparatus required for the simple experiments.—Dr. Gladstone agreed with many points in the paper. Lately he had had to do with schemes for improving the teaching in elementary schools. Children were naturally philosophers, but at present their curiosity was considered objectionable and sternly repressed. Efforts were now being made to alter this state of things. Kindergarten classes in infant schools were a step in the right direction. It was very difficult to introduce analogous methods in the higher standards, but natural science had now obtained a footing. Although the methods of teaching adopted might be those suitable for pure science, care should be taken to put in practical illustrations, for when suitably chosen they are sources of great interest to children.—Mr. Sanderson, in reply, said the slide rule was used throughout the course. Mechanics was taught by actual machines, such as pulley blocks, screw jacks, &c. The boys made some apparatus, but to make all would require too much time.—The President, when proposing a vote of thanks to the author of the paper, said that in Ireland the opinion that boys and girls cannot be taught science greatly predominated. They found considerable difficulty in getting any continuation of the kindergarten teaching sanctioned. Possibly drawing might be allowed, but this seemed all they could hope for at present. He wished to emphasise the fact that in such schools the object was education, and practical applications of science were not important except in so far as it created an interest in the subjects. At present scientific teaching was in an experimental stage, and as in other things, progress is made by trial and error. Many different methods were being tried, and it was important to know which were successful and which failures. He thought the Physical Society might be useful in collecting information on the subject by issuing a circular of questions to science teachers, and subsequently drawing up a report on the subject.

Royal Microscopical Society, December 21.—Dr. R. Braithwaite, President, in the chair.—After the formal business necessary to be done at the meeting preceding the annual meeting, the Society adjourned as a mark of respect to the lately deceased Sir Richard Owen, K.C.B., the first president of the Society.

January 18.—Dr. R. Braithwaite, President, in the chair.—This being the annual meeting the President gave an address on the development of mosses and sphagnums, illustrating his subject with drawings and slides under microscopes in the room.—On the Rev. Canon Carr proposing, and Mr. W. T. Suffolk seconding, a hearty vote of thanks was given to the President for his interesting address.—The annual report and the treasurer's statement of accounts having been read and adopted, the following were elected as officers and council for the ensuing year:—President: Mr. A. D. Michael; Vice-Presidents: Dr. R. Braithwaite, Mr. F. Crisp, Mr. James Glaisher, and Prof. Charles Stewart; Treasurer: Mr. W. T. Suffolk; Secretaries: Prof. F. Jeffrey Bell, Dr. W. H. Dallinger; Ordinary Members: Dr. Lionel S. Beale, Mr. A. W. Bennett, Rev. Canon Carr, Mr. E. Dadswell, Mr. C. Haughton Gill, Dr. R. G. Hebb, Mr. G. C. Karop, Mr. E. M. Nelson, Mr. T. H. Powell, Prof. Urban Pritchard, Mr. F. H. Ward, and Mr. T. Charters White.

OXFORD.

University Junior Scientific Club, February 1.—The President in the chair.—At the conclusion of private business Mr. J. E. Marsh gave an exhibit of some products of the electric furnace. He had brought for the inspection of the club some specimens, from M. Moissan's laboratory, of fused lime and uranium reduced from the oxide. He explained the construction of the furnace, and the methods of using it and of obtaining the temperature of the arc. He further commented on M. Berthelot's views as to the limit of temperature of the furnace, pointing out that the maximum value was that of the temperature of vaporisation of carbon, and that in all cases this was obtained. After a short discussion Mr. F. Finn, who has just returned from Africa on a worm-hunting expedition, described the incidents of his journey. His remarks were illustrated by a number of lantern slides showing scenes on the coast, chiefly at Mombasa and Zanzibar. His first stay was at Lamu, where he did not get any worms, the natives misunderstanding his signs and bringing bones. He described his impressions of Zanzibar at some length, being agreeably surprised at the place. Near here he obtained several reptiles and birds which are now in the Zoological Gardens. His chief collection was made at Mombasa, however. He speaks very highly of the hospitality of the Europeans on that coast.—Mr. F. G. Fremantle read a paper on Hermaphroditism, confining his attention to human beings. He divided his subject into various classes, ranging from complete, or almost complete, neutrality of sex, to those cases where either male or female characteristics preponderated, concluding with some cases of pure deception. The paper was illustrated with diagrams, and a large number of cases were cited in support of the statements made. He showed that a perfect hermaphrodite both physiologically and anatomically could not exist, either the male or female characters preponderating in every case. After a short discussion the club adjourned until February 17.

CAMBRIDGE.

Philosophical Society, January 30.—Prof. T. McK. Hughes, President, in the Chair.—Mr. Bateson exhibited a dog's skull, lent by Mr. J. Harrison of Northampton, in which the upper canines were bigeminous, each having two crowns both in the plane of the arcade.—The following communications were made:—On a new fern from the coal measures, by Mr. A. C. Seward. The specimen described as a new species, *Rachiopteris Williamsoni*, resembles in certain particulars the genus *Myeloxylon*, but possesses distinctive characters not previously recognised in fossil fern petioles. *Rachiopteris Williamsoni* may be briefly described as a petiole with scattered vascular bundles; those near the periphery appear to be rather collateral than concentric in structure, but the larger bundles have a more decided concentric arrangement of the xylem and phloem. Each group of xylem elements is surrounded by a ring of small secretory canals. The hypoderm is like that of *Myeloxylon*, and gum (?) canals are abundantly distributed in the ground tissue. On the intestinal movements of *Daphnia*, by Mr. W. B. Hardy. — On Urobilin, by A. Eichholz, Emmanuel College. In this communication a new method of urobilin extraction was described, by which the pigment is preserved in the state of chromogen. The properties of urobilin in normal and febrile urines were recapitulated in order to compare urobilin with the reduction products from bilirubin and hæmatin. The communication was then devoted to a description of experiments devised to settle the question as to the possibility of artificial production of urobilin from bilirubin and hæmatin. After pointing out how Maly's hydrobilirubin differs from true urobilin, and how consequently the identity of Hoppe Seyler's and Neucki and Sieber's urobilin from hæmatin reduction becomes doubtful, it was shown, in spite of statements to the contrary by McMunn and Le Nobel, that it is possible by complete reduction of both bilirubin and hæmatin to obtain substances in each case accurately resembling urobilin.

PARIS.

Academy of Sciences, January 30.—M. de Lacaze-Duthiers in the chair.—On some objects made of copper of a very ancient date, discovered in the course of M. Sarzec's excavations in Chaldæa, by M. Berthelot. M. de Sarzec has unearthed some relics of the most ancient Chaldæan civilisation, which confirm M. Berthelot's views as to the existence of an age during which pure copper was used instead of bronze, the latter being introduced after the rise of the commerce in tin. A fragment of a small votive figure, found among the foundations of an edifice more ancient than that of the King Our-Nina, was assayed for copper and chlorine by means of nitric acid. It contained neither silver, bismuth, tin, antimony, zinc, nor magnesium; only traces of lead, arsenic, and sulphur, and 77·7 per cent. of copper, the bulk of the rest consisting of alkaline earthy carbonates and silica. Its composition resembles that of the statuette of the Chaldæan King Goudeah, and also that of the sceptre of the Egyptian King Pepi I., of the sixth dynasty, showing that in those early times tin was not known in the two most ancient homes of civilisation.—On the diurnal variations of gravitation, by M. Mascart. A barometric tube enclosing a column of mercury 4·5m. in length, balanced by the pressure of hydrogen contained in a lateral vessel, has been kept surrounded by earth for several years at the Parc Saint-Maur Observatory, only the short upper end emerging from the ground. A study of the daily motions of the column by means of photographic registration has recently, apart from the slow and steady changes due to inevitable differences of temperature, shown sudden variations lasting from 15 to 60 minutes, which can hardly be explained otherwise than as due to corresponding variations in gravitation. They have been as high as 1/20 mm., or 1/90000. The differences of sea-level from high to low water would only produce 1/5th of this variation. The phenomena, if due to subterranean displacements, would be specially interesting in volcanic districts.—On solar statistics for the year 1892, by M. Rod. Wolf.—On the pathogenic properties of the soluble substances formed by the microbe of contagious bovine peripneumonia, and their value for the diagnosis of the chronic forms of this disease, by M. S. Arloing.—The H and K lines in the spectrum of the solar faculæ, by Mr. George E. Hale.—On the differential equations of a higher order, the integral of which only admits of a given number of determinations, by M. Paul Painlevé.—On ordinary linear differential equations, by M. Jules Cels.—On the systems of linear differential equations of the first order, by M. Helge von Koch.—On the theory of spherical functions, by M. E. Beltrami.—Decomposition of alkaline aluminates in presence of aluminium, by M. A. Ditte.—Electrometric study of acid triplatohexanitrite of potassium, by M. M. Vèzes.—Action of water vapour upon perchloride of iron, by M. G. Rousseau.—On two combinations of cuprous cyanide with alkaline cyanides, by M. E. Fleurent.—On the composition of some hydrated alkaline phenates, by M. de Forcrand.—Researches on the acid salts and the constitution of the colouring matters in the rosaniline group, by M. A. Rosenstiehl.—Analysis of medicinal creosotes; gayacol, by MM. A. Béhal and E. Choay.—On an apparatus for the quantitative determination of precipitates by an optical method, by M. E. Aglot.—On the pre-existence of gluten in wheat, by M. Balland.—The evolution of the intestinal gregarinas of the marine worms, by M. Louis Léger.—Origin and multiplication of Ephestia Kuehniella (Zeller) in the mills of France.—On the perithecæ of *Uncinula spiralis* in France and the identity of the American and European *Oidium*, by M. G. Couderc.—Histological researches on the *Uredinei*, by MM. P. A. Dangeard and Sapin-Trouffy.—New geological observations in the French Alps, by M. W. Kilian.

QUALITATIVE CHEMICAL ANALYSIS.

Qualitative Analysis Tables and the Reactions of certain Organic Substances. By E. A. Letts, D.Sc., Ph.D., F.R.S.E., F.C.S., &c. (Belfast: Mayne and Boyd, 1892.)

THE author in his preface says, "Every teacher has his own methods—acquired not only from his experience, but also largely through the researches of others—and this book embodies mine." Therefore the volume cannot fail to be welcome to those who take an interest in the teaching of analytical chemistry. But it is surprising to find that Prof. Letts has until quite recently followed the old method of dictating reactions and methods to his students, and allowing them to work from their own notes. For the last fifteen years there has been no lack of text-books of qualitative analysis, and Prof. Letts has found, what probably all teachers of the subject are aware of, that students rarely take accurate notes. But, however exact they may be, every one knows that manuscript is not so easily deciphered nor so readily referred to as a printed page.

The methods of work given are, of course, more or less on the ordinary lines. The final test for bismuth depends upon the production of its black suboxide, and this reaction has much to recommend it, though probably many would prefer the oxychloride reaction. The use of ammonium molybdate as a separative reagent in qualitative analysis we do not consider advisable for many reasons, but no complaint can be lodged against it on the score of its accuracy.

There can be no doubt whatever that both Prof. Letts and his students will find considerable advantage in the use of boldly-printed statements of methods. But the author begins his preface by stating that although the book has been written chiefly for his own students, he will be glad if it prove of service to others also. This lays the volume open to general criticism, and prompts us to complain that it is neither so clear nor so systematic as it might have been. As to the want of clearness, there are a few expressions that can easily be altered in a second edition, and these we lay no particular stress upon. For example, at page 27, in the description of Bunsen's dry tests, we read:—"The charred end of the match is next moistened with fused carbonate of soda." At page 40 it states that the solution "is mixed with its own volume of chloride of ammonium." One assumes this to be a solution, but if so the strength of it is not given, and we fear that the bulk of the solution to which it is to be added will be likely to vary enormously according to the peculiarities of the student and the character of the substance he is at work upon.

The more important want of clearness may be exemplified by taking the case of a student who has Epsom salts given to him as a simple salt. This can hardly be called an out-of-the-way substance, but so far as we can discover, the student in following these tables would examine it by the following series of operations: Heating on platinum wire to see the colour of the flame. Heating on a borax bead in the outer and inner flames. Heating on a carbonate of soda bead. Heating on charcoal (if a white mass resulted, which with cobalt nitrate gave a "faint pink," the metal might be recognised here, but as magnesium sulphate does not readily yield this reaction in most cases the student would pass on). Heating on charcoal with sodium carbonate. Heating in a glass tube closed at one end. Repeating with bisulphate of potash. Repeating with black flux. Repeating with magnesium wire. He would then dissolve the substance in water, and test a part of the solution for ammonia by heating it with caustic alkali. Then heat a part on a platinum wire for the flame colouration, a test that has already been done on the solid, and then pass on to the examination of the solution in the ordinary way for the base, and finally search for the acid if it is not already found. It may be taken for granted that this fiddling about with the substance is not intended, but the volume does not appear to contain directions as to how to go more directly to work.

The want of system that we complain of is acknowledged by the author himself in picking out certain parts and labelling them as "systematic." If the whole were systematic this distinction would obviously be meaningless. As this fault exists in many of the text-books and in much of the teaching that we have had experience of, we are tempted to make a few general remarks upon the matter without special reference to the volume under notice.

That qualitative analysis is often regarded as a very unimportant branch of chemistry, may account for its comparative neglect. One constantly meets with students who are able to perform quantitative operations of not too complex a character with commendable accuracy, and that can with a little guidance do many sorts of "research work," but are wholly unable to perform with certainty a qualitative analysis of a comparatively simple substance. They may happen to find most or all of its constituents, but they have no confidence in their result; they do not feel sure that they have missed nothing, or indeed that everything they have found is unmistakably present, and generally they have little if any idea of the degree of accuracy of their work. They cannot distinguish between a principal constituent and one that is present in a comparatively small proportion. This incompetency must be ascribed very largely to the fact that students are too often urged on to work that a casual observer might regard as more important. The foundation is neglected for the sake of the superstructure.

But having regard only to that amount of practice in qualitative work that still remains possible for the average student, there is too often a lack of method that is surprising if not disastrous. As a rule, it is considered desirable to get first an idea of the general character of the substance given for examination by a few dry tests, but these, as often done, are not only of no use, but serve in a conspicuous manner to train the student in the making of careless and imperfect observations, and in the dodging about from one operation to another with no idea of the proper sequence or inter-dependence of the various parts of the work. In the analytical examination of even the simplest of substances, from the time when the student receives it until he has made his last note, every operation ought to be in an order for which very definite reasons can be given, and the completed work ought to be of such a character that anything added to it would be superfluous; anything taken from it would leave it imperfect; and any change in the order of its various parts would be to its detriment. This character of work is generally sought after in the separation of metals from a solution; but the rest of a qualitative analysis, namely the preliminary examination and the testing for acids, is too often a collection of odd operations, which, if the student is lucky, will lead him sooner or later to the desired result, but if he is unlucky may fail to do so through no fault of his own.

Chapman Jones.

POPULAR LECTURES ON PHYSICAL SUBJECTS.

Gemeinverständliche Vorträge aus dem Gebeite der Physic. Von Prof. Dr. Leonhard Sohncke. (Jena: Gustav Fischer.)

IT is a matter of common remark that the books on scientific subjects which reach us from Germany are, as a rule, so special and detailed in character as to be totally devoid of interest, except to those immediately concerned with the subjects of which they treat. This being the case, it is all the more refreshing to meet with such a collection of popular addresses as Prof. Sohncke has gathered together in the volume before us. He has not restricted himself in his choice of subjects to any one branch of physics; on the contrary, the nine lectures of which the book is made up represent as many different divisions of natural philosophy, and were delivered quite independently before various audiences in Germany.

The first lecture of the series bears the somewhat obscure title, "What then?" and was suggested by a great strike among the coal-miners of Westphalia, which led to a temporary cessation of the German coal supply. The author depicts what would be the consequences if the world's coal supply were exhausted, in terms almost as pathetic as those of Prof. Jevons which moved an English Parliament to appoint a commission on the subject. But recognizing that, after all, coal is only stored up solar energy, Prof. Sohncke endeavours to look at the brighter side of the question by discussing the possibility of utilising the sun's energy in other forms, and so enabling man to remain "lord of creation" even in those days when the entire available coal supply of the world reposes on the shelves of some scientific museum.

Equally spontaneous is the lecture on "Migratory Mountains," in which an account of a holiday visit to the north-east corner of Germany gives an opportunity of describing the formation and movements of the mammoth sand-dunes in that locality.

Of the other lectures, that entitled "The revolution in our views concerning the nature of electrical actions" will probably commend itself to most readers because it treats of a subject now exciting general interest. It contains a short history of the arguments and experiments which led to the substitution of the ether theory of electrical action in the place of the older action-at-a-distance theories. While admitting the existence of a medium which transmits both optical and electrical disturbances, the author thinks it more probable that gravitation is a true action-at-a-distance, and in so doing he tacitly denies that a medium is a necessity. The notion of an empty space is so foreign to English men of science of this generation, that we certainly consider Prof. Sohncke's summing-up of the question to be worthy of attention. He says:—"Even if we could finally succeed in proving that action-at-a-distance is really the result of a transmission through some medium, we must not suppose that all difficulties are then removed. For the process of such a transmission is by no means simple, and cannot be explained without further assumptions; on the contrary, very formidable difficulties arise even here. Directly we try to give a concise explanation of the compression of a body and its subsequent expansion when performing elastic vibrations, we find that a choice must be made between two assumptions equally hard to accept. Either matter is itself capable of compression and expansion, or else it consists of separate vibrating atoms to which we must assign the property of exerting mutual forces on each other at a distance."

From a purely scientific standpoint, the lecture on "Newer theories of atmospheric electricity and thunderstorms" is undoubtedly the most valuable of the series, the subject being one on which Prof. Sohncke can speak with some authority. After describing the older theories of the origin of electrical charges in the atmosphere, he discusses those newer ones which were suggested by the discovery of Hertz that ultra-violet light facilitates the discharge of electricity from a charged body. Of these the best known is that of Arrhenius, who supposes the air, ordinarily a dielectric, to be rendered feebly-conducting by the action of light. According to this theory, the earth is negatively charged, and when its atmosphere is illuminated some of the charge is conducted away to the clouds. The conduction must be electrolytic, otherwise the air would become charged. Prof. Sohncke objects to this theory mainly on the ground that the discharging action of light cannot be considered as due to the air in any way, since it is manifested only when the light vibrations fall on, and are absorbed by, the negative electrode. Further, it is not easy to see how elementary gases such as oxygen and nitrogen can be electrolytes. In concluding he defends his own theory, according to which atmospheric electricity is produced when a cloud laden with particles of ice meets another charged with water drops, the electrification being due to the friction of ice against water. In support of his view the author quotes the fact that hailstones are found to be electrified on reaching the ground.

The appearance of a volume like the present one invariably gives rise to some regrets that the whole earth is no longer of one language and one speech, but we hope that some friend of popular science may be induced by the contents of the book to furnish a translation for English readers.

James L. Howard.

BRITISH JURASSIC GASTEROPODA.

A Catalogue of British Jurassic Gasteropoda, comprising the Genera and Species hitherto described, with references to their Geological Distribution and to the Localities in which they have been found. By W. H. Hudleston, M.A., F.R.S., P.G.S., and Edward Wilson, F.G.S. 8vo, pp. xxxiv+147. (London: Dulau and Co., 1892.)

NEXT in importance to a monograph on any group of fossils is a catalogue of the species giving their distribution, their synonymy, and references to the figures and descriptions. The value of such a catalogue is enormously increased when, as in the present case, the authors have made a prolonged and careful study of the subject. The late Prof. John Morris was able, with scarcely any help from other workers, to publish a critical catalogue of all British fossils; the first edition appeared in 1843, the second in 1854. But since that date so much progress has been made in palæontology that the accomplishment of such a task by any one man would now be an impossibility. Prof. Morris always hoped to bring out a third edition of his work, and after his death a committee was formed to carry out this project. But the labour appears to have been too great and the committee soon ceased to exist. This is greatly to be regretted, for although the work must of necessity have been distributed among various authors, a certain amount of uniformity in treatment would at any rate have been secured and publication hastened.

In the preface we are told that Mr. Hudleston is mainly responsible for the Oolites and Mr. Wilson for the Lias. Under the term Jurassic the authors include everything from the Lias to the Portland-stone: the Rhætic beds, although not regarded as strictly Jurassic, are treated in the supplement. The total number of gasteropods recorded by Samuel Woodward from these formations in 1830 was only 89, whereas in the present work the number given is 1015. Of these 15 come from the Rhætic, 314 from the Lias, 681 from the Oolites, and 5 from the Lias and Oolites. In the Lias the gasteropods are characterized by the species belonging to comparatively few genera. Although, as far as genera are concerned, the Lias shows considerable affinity to the Oolites, there is nevertheless a great break in the continuity of the species, only five being common to the Lias and Oolites. Gasteropods are most abundant in the calcareous beds, so that the Lower Oolites have yielded by far the larger number of forms, the Inferior Oolite being richer than the Great Oolite. In the Middle and Upper Oolites there is a decided decline in the gasteropods, especially of the argillaceous beds.

After the introductory remarks the authors give a valuable bibliography of the British Jurassic Gasterpoda, and then a list of the genera, in which each is placed in its proper family and reference given to the original description. By the use of different type the genera are divided into four classes, (1) those fully accepted by the authors, (2) those accepted with doubt, (3) those given as Jurassic by other authors but not accepted, (4) synonyms. In the catalogue proper the authors have adopted Morris's plan, each page being divided into two columns; in the larger are given the name of the species, the references, the synonyms, and the cross-references; in the smaller the geological horizon and the more important localities, the locality first named being that from which the type was obtained or the first place from which the species was recorded in Britain. The dates of publications are often omitted, but since they can be found in the bibliography this is not very inconvenient except in the case of serials. The present *locale* of types is not given, although this would have been a comparatively easy matter, especially since so many catalogues of types have been recently published.

With regard to the orthography the authors have kept to the older and more usual method. For instance, the capital initial is used for species when derived from proper names, and the single *i* for the genitive is not always adopted. Thus we find a considerable variation in the terminations, such as, *Cricki* (p. 124) *Crickii* (p. 77), *Waltoni* (p. 42) *Waltonii* (p. 139), *Suessea* (p. 29) *Suessii* (p. 138), *Wrightii* (p. 46) *Wrightianus* (p. 70). These are, however, purely matters of opinion and do not in any way detract from the great value of the work, which exhibits so much painstaking accuracy and sound criticism.

H. WOODS.

OUR BOOK SHELF.

The Year-Book of the Imperial Institute of the United Kingdom, the Colonies, and India, and Statistical Record of the Resources and Trade of the Colonial and Indian Possessions of the British Empire. Compiled chiefly from official sources. First issue 1892. Issued under the authority of the Executive Council, and published by John Murray, &c. Large octavo pp. xvi. and 824.

THE Imperial Institute has lost no time in issuing a handsome and comprehensive year-book, compiled by the Librarian, Mr. J. R. FitzGerald, who has diligently and successfully gathered together a stack of varied information bearing on the purposes of the Institute. It is a question which time alone can answer whether amongst the many admirable year-books of statistics, commerce, and the colonies which have established themselves as annuals of proved utility, there is room for a new and bigger book overlapping their information, and containing few, if any, novel features. It would be out of place to discuss this question in a notice which ought to be confined to the scientific aspects of the work. The object of the year book, as expressed in the preface, is to deal "statistically with the physical geography, the natural resources, and the industries and commerce of the Colonies and India," and with certain other related facts. It would not be fair to criticise severely the first issue of so large and comprehensive a compilation; but it would help towards the attainment of the compiler's aim if the description of the physical geography of the regions touched upon could be made as full as the historical introductions, and as statistical as the commercial tables. More notice ought to be taken of the geology and the character of the soil in the colonies where geological surveys are in progress; and climate certainly deserves better treatment. We do not think space would be wasted in giving the mean monthly temperatures and rainfall for the average year, and for two extreme years, at a few representative stations in the larger colonies. This information cannot indeed be found in any existing books, but must be worked out from original records which exist abundantly, and are rarely made available to practical workers.

The treatment of natural resources might also be improved by a firmer grasp of scientific principles. The commercial statistics are, as might be expected, much fuller, better arranged, and more serviceable than those relating to physical geography; but we imagine that few members of the Imperial Institute, likely to make use of the book, are without the original records relating to their own department. The difficulty of proportion and perspective is rather seriously apparent in the treatment of India, which has to be passed over more lightly than the colonies, because equal detail would involve the sacrifice of much space. Thus the great internal trade of India is scarcely touched upon, and the wants and tastes of consumers in the ultimate Indian market, by whom imports are finally absorbed, are not laid before the British merchant.

Beneath Helvellyn's Shade. By Samuel Barber. (London: Elliot Stock, 1892.)

THIS book consists of notes and sketches in the Valley of Wythburn, and is brightly and attractively written. Perhaps the best chapters are those on clouds, the various forms of which have been carefully studied by the author. He has also many interesting remarks on various aspects of Cumberland scenery, on the customs of the people, and on antiquities. Occasionally, perhaps, Mr. Barber adopts too much the tone of a preacher, but his impressions and ideas are for the most part fresh and vivid. The book will especially please those who have themselves felt the charm of Wordsworth's country.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Dr. Joule's Thermometers.

RESPECTING the question asked by Mr. Young (NATURE, vol. xlvii. p. 317), I am glad to have an opportunity of stating that shortly after Joule's death I obtained the sanction of his son to examine the scientific apparatus that were left in his house.

I found a number of thermometers, and amongst them the two chiefly used by Joule in his researches. These thermometers have been placed in my charge for the present. I have made careful comparisons of them with a standard of the "Bureau international des Poids et Mesures," and therefore indirectly with the air or hydrogen thermometer. A standard issued by the Technische Reichsanstalt has also been used as a check. I spent a good part of last winter on the work and am now only waiting for an opportunity to repeat some of the measurements. The results will be published in due course, and I think will prove of interest. As Joule compared his thermometers with one used by Rowland, we shall in this way have an indirect comparison of Rowland's air thermometer with those by which the Berlin and Paris standards have been independently fixed.

One question arises on which I should be glad to have some information, and I should be grateful to any of your readers who could help me. The glass of which Joule's thermometer is made does not behave like the English glass now in use; and it would be important to know the probable composition of glass used in England about the year 1840 for thermometric purposes. As my experiments are not concluded I do not wish to speak with too great a certainty; but I believe it will be found that if we could return to the glass of Joule's thermometer, we should have a substance as well and possibly even better adapted to the manufacture of thermometers than the modern Jena or French thermometer glass.

I am sorry I cannot give a very definite answer to Mr. Young's question. Joule does not, as far as I know, anywhere give the actual readings of the freezing point, but only its changes. Rowland, in quoting the comparison between Joule's thermometer and his own, gives 22·62 as the actual reading of Joule's zero. I have not at the present moment access to Rowland's paper, and have no note of the date at which this comparison was made (either 1879 or 1880).

Such a formula as that given by Mr. Young can, however, only have a limited application. The zero of a thermometer depends on the temperature at which the thermometer has been kept previous to its immersion into ice, and with properly-annealed thermometers the secular changes are much smaller than the temporary ones. Last winter Joule's thermometer showed changes in zero from 23·51 to 23·00 on the arbitrary scale, the original temperatures varying from 7° to 30°.

All observations lead to the conclusion that the secular changes of a thermometer gradually vanish, so that the zero corresponding to any temperature approaches a limit. Mr. Young's formula would make the zero rise indefinitely.

ARTHUR SCHUSTER.

Dust Photographs and Breath Figures.

YOUR two correspondents on February 9 add interesting instances of these phenomena. I am sorry that one of my statements was not clear. In saying "Two cases have been reported to me where blinds with embossed letters have left a latent image on the window *near* which they lay," I meant to describe them as not in contact.

I have questioned my neighbour Dr. Earle again as to his case. The plate-glass window of an hotel in London has on the inside a screen of ground glass lying near but not touching: upon the latter are the words "Coffee Room" in clear unfrosted letters. One day as he was at breakfast the screen was taken away, but the words were left plainly visible on the window, and no washing would remove them. The other case is curiously similar, but each narrator was ignorant of the other's tale. A friend, Mr. Potter, asked me if I knew whether a house in which he was lodging had been an hotel, for on misty days they saw "Coffee Room" on one of the windows. I remembered the house had been an hotel two or three years previously, and there had been brown gauze blinds with gilt letters.

Mr. Thiselton-Dyer's observation appears not so much akin to these two as to the dust picture of a water-colour drawing of which I spoke in my former paper.

I look forward to seeing the effects at Canterbury.

Winchester College, February 13. W. B. CROFT.

Fossil Plants as Tests of Climate.

MR. DE RANCE'S note relating to the above subject in NATURE, p. 294, mentions that "Heer has determined a magnificent flora of more than 350 species from these northern tertiaries, and that he at once pointed out the absence of tropical and subtropical forms." My contention, founded on an attentive study of his determinations and of the original specimens in London and Dublin, and to some extent in Copenhagen, is that not fifty, or perhaps not the half of fifty, of these determinations are entitled to the smallest weight; and again that though at first he saw nothing subtropical in the flora, he subsequently declared the presence of palms, &c., upon utterly insufficient data. While, however, wishing to rid the "magnificent" flora of 300 or more useless and misleading encumbrances, I am far from wishing to depreciate the extraordinary significance and value of that which remains, and which clearly shows that in early Eocene times the coast of Greenland supported in certain places forests which included the redwood, the plane, and even the magnolia, associated with many more northern forms. This is consistent with the tropical vegetation existing during a part of the possibly contemporary lower tertiary period in the south of England. Both facts are sufficiently inexplicable, but there is no occasion to magnify the difficulties they present. As to the Greenland floras they have not been proved to contain any forest trees that might not, and which in fact do not, flourish in their modern representatives, when planted in certain favourable spots on the west coast of Ireland, and even of Scotland. We are not even obliged to assume that Greenland as a country was characterised by such vegetation, for this might be as erroneous as to regard Ireland or Scotland as countries generally characterised by forests of arbutus. The flora of a country is in fact most likely to be preserved in its most sheltered spots, in lake bottoms like parts of Killarney, or where small rivers quietly steal into the tidal waters of deeply recessed bays like those of Bantry and Kenmare, in forest pools like some in the Mount Stewarts' woods of Bute, and in the backwaters and marginal pools of the lower reaches of larger rivers; we are not only entitled, but we are bound to consider this to have been the case in Greenland, and to base our estimate of its climate in the lower tertiaries upon this view and no other. Now what geologists and physicists ought to do, and what they resolutely won't do, is before going farther afield for cause and effect, to take the map of the world on Mercator's projection, and consider how far, if the Atlantic were a closed ocean to the north, as we know it must have been, the required climatic conditions would be produced. The difference between the arbutus nooks of Ireland on the one side and the desolation of Labrador on the other is brought about solely by ocean currents. At the period of the Greenland floras the arctic currents were excluded, and consequently the whole Atlantic basin was filled with the circulation of equatorial and temperate waters only. The distribution of plants and animals renders it extremely probable that during much of the tertiary period, the antarctic waters were equally excluded from the Atlantic by land connecting Africa and South America. What, under these circumstances, would happen to the climate of the Atlantic littoral? It would, it appears to me, be more philosophical to dispose of this question, which is supported by a weight of evidence, before invoking shifting of the earth's axis, or other hypothetical causes supported by none. J. STARKIE GARDNER.

London, February 13.

An Optical Phenomenon.

IN NATURE, vol. xlvii. p. 303, you mention that "a beautiful optical phenomenon, which has not yet been satisfactorily explained, is described by M. F. Folie in the *Bulletin* of the Belgian Academy." From what follows, it is evidently the same as that described in Tyndall's "Glaciers of the Alps" (Murray, 1860), p. 177 *et seq.* Tyndall gives a description of it in a letter from Prof. Necker to Sir David Brewster, from which I quote the following:—"You must conceive the observer placed at the foot of a hill between him and the place where the sun is rising, and thus entirely in the shade; the upper margin of the mountain is covered with woods, or detached trees and shrubs, which are projected as dark objects on a very bright and clear sky, except at the very place where the sun is just going to rise; for there all the trees and shrubs bordering the margin are of a pure and brilliant white, appearing extremely bright and luminous, although projected on a most brilliant and luminous sky. You would fancy you saw these trees made of the purest silver."

Prof. Necker says that he saw it at the Saleve, which is not so high above the Lake of Geneva as some of our British mountains above the sea, and has no permanent snow near it; so that M. Folie's suggestion, that it is due to light reflected from snow, must be wrong. I have seen it from the König-See, near which I believe there is no permanent snow.

This appearance is always to be seen under the circumstances described, when the sky is clear and bright enough. I had read of it in Tyndall's book, and when in the Alps I sought for and found it. I have often seen a distant approach to it produced by furze bushes, quite near, seen against sunlight, and by leaves against moonlight. JOSEPH JOHN MURPHY.

P.S.—Ruskin somewhere describes this phenomenon.

Belfast, February 6.

Foraminifer or Sponge?

A PAPER by A. Goës "On a peculiar type of Arenaceous Foraminifer from the American tropical Pacific, *Neusina Agassizi*," has just been published in the "Bulletin of the Museum of Comp. Zoology, at Harvard College," vol. xxiii. No. 5, in which the author describes some remarkable forms dredged by the *Albatross* expedition in the Pacific of Central America. They are supposed to be foraminifera, are of leaf-like shape, measure up to 190 mm. in breadth, and are marked by concentric lines of growth. Their interior shows a stroma, consisting of fine chitinous threads, enclosing sand and *débris* of shells. Without wishing to recapitulate all the various points of structure, I will only say that there can be no doubt that these forms belong to Hæckel's deep sea keratosa (see *Challenger* report, vol. xxxii.) from the tropical Pacific, and I should think that *Neusina Agassizi* is identical with *Stannophyllum zonarium*, Hæckel. I happen to have here a *Challenger* specimen of this latter species, kindly lent to me by the Manchester Museum, and its microscopic examination convinces me of the identity of the two forms.

University College, Liverpool. R. HANITSCH.

Unusual Origin of Arteries in the Rabbit.

TOWARDS the close of last month Prof. W. N. Parker reported in your columns an abnormality in the veins of the rabbit, and although the same interest does not attach to it, it may be worth while recording an unusual arrangement of the vessels arising from the aortic arch. In the case which has just come under my notice, the two carotids arise together from the arch, at the point usually occupied by the innominate artery, while the right subclavian artery arises beside the left subclavian, which occupies the usual position. PHILIP J. WHITE.

University College of North Wales, February 7.

Holmes's Comet.

ON February 11, 10h. to 10h. 35m., I re-observed this object with powers of 40 and 60 on my newly-silvered 10-inch reflector. The comet was in the same field as β Trianguli and south preceding that star. I found it fairly conspicuous. The nucleus, or brighter portion of the head, presented a distinctly granulated appearance. Applying a power of 145, single lens, I saw that it really consisted of a number of very small knots of nebulosity, so closely approximating the stellar form that they might readily have been mistaken for one of the very faint, barely resolvable clusters in which the components are only to be caught by glimpses. The multiple nucleus was involved and surrounded with feeble nebulosity, and a faint tapering tail flowed from it in a N.E. direction. I believe that outlying this there was an excessively faint fan-shaped tail, but could not be absolutely certain.

The sky was not good, being lighter than usual, with suffused mist. On February 12, at 10h. 15m., I picked up the comet again, but details were invisible, owing to the veil of thin cloud overspreading the N.W. sky at the time.

Bristol, February 13. W. F. DENNING.

HELMHOLTZ ON HERING'S THEORY OF COLOUR.

THE following translation of the critical account given by von Helmholtz of the colour-theory of E. Hering, in the new edition of his *Handbuch der Physiologischen Optik*, commencing at page 376, has been made by Prof. Everett for NATURE. The translator aims at clearness rather than literal rendering, and three obvious misprints in the paragraph on the transformation of coordinates have been corrected. "Lambert's colour-pyramid" is another name for the "cone of colour" described in Maxwell's papers and in § 1074 of Everett's "Deschanel."

This much-talked-of theory is a modification of Young's theory, which, by the choice of other fundamental sensations, endeavours to give better explanations of what it regards as immediate facts of internal observation. It assumes three elementary sensations, related to three different parts of the nerve-apparatus or "visual substance." Two at least of these physiological processes exhibit the opposition of positive and negative. One of the three "visual substances" gives in the condition of excitement the sensation of white, and in the condition of rest the sensation of black. The second gives the two sensations of blue and yellow, which are accordingly designated "opposed colour-sensations." The third gives the other pair of "opposed colour-sensations," red and green. But by "red" is denoted not the colour usually so called, but the complementary of green, which is purple.

It is possible to specify "elementary sensations" (in the sense in which we have previously defined the term) which would correspond to Hering's elementary sensations, and would be capable of giving by their combination all other colour-sensations. If we take three rectangular axes of coordinates, x, y, z, as the edges of Lambert's colour-pyramid, x corresponding to red, y to green, and

z to violet, Hering's coordinates u, v, w will have the values

$$u = \frac{x + y + z}{\sqrt{3}}, \quad v = \frac{x - z}{\sqrt{2}}, \quad w = \frac{x - 2y + z}{\sqrt{6}}$$

u denoting the white element, and being measured along the axis of the pyramid; w denoting the red-green element, and being measured at right angles to the axis of white, in the plane containing the green edge of the pyramid; v denoting the yellow-blue element, and being measured at right angles to the plane of u, w.

Positive values of w correspond to purple red, and negative values to green. Positive values of v correspond to yellow, and negative values to blue.

I give these equations in this definite shape for the purpose of showing, by a definite system of representation, that the arbitrariness which attends the choice of three colours, in terms of which the rest are to be specified, affords sufficient latitude to admit of the employment of three such different specifying elements as are adopted by Hering.

If only positive values of x, y, z are to be admissible, the expression for u shows that every kind of light must excite the white sensation positively, and consequently that no kind of objective light can produce a pure sensation either of the red-green or of the yellow-blue kind. Hence the pure unmixed "opposed colour-sensations" are such as we never have had or can have, and are separated from all colour-sensations that we have ever had by a much wider gap than the pure sensations which Young's theory supposes, although these latter extend somewhat beyond the range of objective colours. By subjecting portions of the retina to special influences (as we shall explain in treating of after-images) we can at least approximate to Young's elementary sensations; while these same methods, when we attempt to approximate to Hering's pure sensations, give results opposite to what his theory would lead us to expect.

Hering assumes, in accordance with the brief expression of his theory in the above equations, that white light excites only the white-black visual substance and excites it always positively; that yellow light, besides doing this, excites the blue-yellow visual substance, as does also blue light, but in opposite sense. On the other hand, when blue and yellow lights are in exact equilibrium, they have no action on the blue-yellow visual substance.[1] Similar remarks apply to the excitements of the red-green visual substance by red and green light.

The sensation of luminosity is identified by Hering with the sensation of white. He accordingly maintains that the pure sensation of blue or of yellow involves no sensation of luminosity. I must confess that personally I can form no conception of a colour which has no degree of less or greater luminosity, and therefore think such an abstraction not tolerable in a system which, on other points, makes its appeal to the immediate testimony of inner consciousness, and claims by this means to establish its superiority to other systems.

Differences of intensity must, however, occur in the opposed colour-sensations if they involve no difference of brightness. In comparing saturated blue with equally luminous pale blue, Hering would regard the white sensation as equally intense in both, but the blue sensation as stronger in the saturated blue.

As the physiological basis of the "opposed colour-sensations" Hering takes the two opposite processes of organic change, namely, the decomposition of the organic mass by activity, and its restoration under the influence of the circulation of the blood, which carries oxygen stored up in it and feebly united with it. The former process is called *dissimilation*, and the latter *assimilation*. Which of the two opposed sensations corresponds to dissimilation and which to assimilation is left undecided, both in the case of blue-yellow and of red-green. The physiological improbabilities of this assumption have in part been pointed out already, and we shall return to the subject in treating of after-images.

This assumption of double nerve-working was originally applied by Hering to the white-black visual substance also. At the present time he adheres to the hitherto-received doctrines of nerve-physiology to the extent of holding that, in the case of this substance, all light excites only dissimilation and the sensation of white; and on the other hand want of light produces only assimilation and restoration of excitability. That during this latter process a sensation of darkness is experienced, all are agreed. The difference is purely theoretical. According to the older view, which I have defended, we must, in order to perceive that there is luminosity in a particular part of the field of view at a given time, be able to distinguish at another time that this perception is wanting. This perception that a sensation which might be there is not there contains in itself a testimony as to the condition of the organ at the time, which is different from all sensations of incident light; and in this sense we call it also a sensation—the sensation of darkness.

Hering, on the contrary, maintains that the sensation of black must have its own special physiological basis of excitation, and seeks it in assimilation, going on in the white-black visual substance.

From the foregoing account the reader will gather that Hering's theory, if we overlook its physiological views, is able to explain all hitherto established facts of colour mixture as well as, but not better than, Young's theory. It differs only in its special choice of elementary excitations; and this choice, if we admit negative values of them, suffices for expressing the facts, just as any axes of co-ordinates suffice for a problem of solid geometry.

Hering's objections to Young's theory reduce themselves, in his latest statement, to the following:—

"In the Young-Helmholtz theory, the assumption of the three elementary colour-sensations is *à priori* repulsive, because these sensations are not presentable; and notoriously, according to necessity, now one set and now another set of elementary colour-sensations are assumed."

As to this, I have already remarked that the fundamental sensations of Young's theory, in so far as they differ from objective colours, can be approximated to, by the method of partial fatigue of the retina, much more closely than Hering's pure opposed-colour-sensations. If different upholders of Young's theory have made different assumptions as to the three primary colours, and have assigned different weights to various facts which bear on the distinction, this affords no justification whatever for the imputation that they have changed their assumptions according to necessity. It is always better to acknowledge existing doubt than to dogmatise.

Hering goes on, "If the excitations belonging to the three elements have correspondingly distinct physiological causes, one would expect that these sensations would have something special about them."

This they have, in my opinion, in the prominent glow of colour-saturation; for which, again, the theory of opposed-colours furnishes no basis of explanation.

He continues, "Yellow gives, for example, much more the impression of a simple or elementary sensation than violet, and yet we are told that the latter is an elementary sensation and the former a mixture of simultaneous sensations of red and green, or at least, in some way, the product of the simultaneous existence of the principal excitations corresponding to these two elementary sensations."

What a deceitful test apparent inner consciousness is in such matters, we can see from the examples of two such authorities as Goethe and Brewster, both of whom believed that they saw in green the blue and yellow, of which, being misled by experience with pigments, they believed it to be composed.

---

[1] This was a point which Hering left doubtful in the earlier statements of his system, so that it was not clear whether he assumed three or six independent variables. According to his more recent explanations the statement given in the text may fairly be said to represent his view.

He goes on, "Helmholtz says, quite correctly, 'so far as I see, no way has been found of determining one of the elementary colours except the investigation of colour blindness.' This investigation has notoriously not confirmed Young's theory."

This would, even if it were true, be in itself no argument against the admissibility of the theory. The theory of colour-blindness seems, as we shall shortly see, to be a particularly hard crux for Hering's theory; while the hitherto well-established facts of red-blindness and green-blindness admit of comparatively easy and perfect explanation by Young's theory.

He adds, "And the three sets of fibres, which, however, as Helmholtz remarks, are not essential to the theory, have hitherto been sought for in vain."

This objection applies to Hering's theory as much as to Young's.

The reader will easily convince himself that these objections are of no weight whatever. He follows them up by an enumeration of contradictions and inaccuracies which he professes to have found in Grassmann's and my own explanation of Newton's law of colour-mixture, and partly also in that of Kries, errors which, even if they existed, would in no way tell against Young's theory, but only against its interpreters. Here, however, the obscurity seems to me to lie on the side of our opponent.

These objections arise out of the fact that, in mixtures of a saturated colour with white, the tint of the mixture sometimes seems changed (pale red for example approaches more to rose, and pale blue to violet); and that, on the other hand, with increase of intensity, the colours of the spectrum appear sometimes paler, sometimes yellower. But if we speak of those elementary excitations which, from the point of view of Newton's law, are alone entitled with certainty to the name of elements, as being able to coexist without mutual disturbance, then the only sensation which can with certainty be regarded as corresponding to the coexistence of a white and a red elementary sensation is that which comes into existence under the simultaneous influence of the corresponding white and red lights. The term "elementary sensation" is in this connection to be taken, of course, not in the narrow sense of Young's hypothesis, but in the wider sense above explained—the sense in which we speak of linear relations between colour-sensations and linear superposition of elementary-sensations. In the domain of colour-mixture we know nothing of any elements but these superposable ones; and if we would preserve a constant meaning for our colour-equations we must interpret them in this sense, as I have explained above. This is what H. Grassmann and myself have always done.

Moreover, erroneous estimates of the difference between a pale and a more saturated colour are liable to be made, and hence those colours which are really most diluted with white do not always appear the palest. If, without sufficient experience of colour-mixture, we only guide our judgments by similarity of sensations, we are liable to make mistakes as to which colour contains white. The question of the power of perceiving differences will therefore arise. Further, it is found that colours of very strong luminosity do not differ so much from one another in the sensations they produce as colours of moderate luminosity,—a fact which finds its explanation in Young's theory, of which it is a natural consequence. Colours when highly luminous appear more similar to one another and more similar to white. We express this by calling them pale as compared with colours of feebler luminosity. I have, however, already mentioned that the law of superposability ceases to be applicable when the luminosity is excessive.

Nevertheless, in view of the fact that simple colours of high luminosity are always as saturated as colours of such luminosity can be, it is not necessary, or rather it is not correct, to designate them as less saturated. The true statement is that differences of tint become more uncertain at high intensity—an uncertainty which attaches also to the estimation of the intensity itself, as has long been known.

If Hering's sensation of white and opposed-colour-sensations are truly to deserve the name of elements or constituent parts of sensation (as he plainly intends, since he assigns to them special visual-substances), either he must acknowledge them as the elements deducible from the law of addition, or else they are purely hypothetical processes of whose existence and superposability no one knows anything. His polemic against Grassmann and me then amounts to this—that at a time when his hypothesis had not been propounded we did not speak in the sense of it.

Hering seems to regard as the chief point of superiority of his own hypothesis its closer conformity with the names which have established themselves in language—names which, as I have explained above, relate rather to the colours of material bodies than to the colours of light. To this circumstance it is, in fact, indebted for a certain amount of popularity and facility of apprehension. He himself assumes that these names have sprung from an immediate perception of the simple elements of sensation by a kind of inner consciousness, and thinks that he has thus very certain and immediate knowledge of the pure red-sensation, the pure white-sensation, and so on.

In his publication of 1887 he has discussed the possibility of assuming, instead of three or six simple processes of sensation, a larger and perhaps indefinitely great number, and a corresponding number of "elementary powers" for the several kinds of objective light. He, however, gives the geometrical representations of such actions in such a manner that practically these powers all depend on three independent variables. On the other hand, as regards these independent variables, which are the most important factors in the problem, he gives as good as no clue to them; he only seeks to remove them as far as possible from the sphere of physiology. For my own part I am able to understand this whole series of descriptions only as meaning that an arbitrary number of visual substances can be assumed to exist in the brain, and that their respective strengths of excitation are different functions of the same three independent variables, each visual substance being unaffected by the excitations of the rest, and the excitation of each being susceptible of direct apprehension in consciousness. I do not think it is necessary, in this book, to go further into such hypothetical views.

Hering especially claims the credit of opening up the way to understanding colour-blindness. He makes all dichromasy depend upon a single cause, namely want of sensibility in the red-green visual-substance. The difference between red-blindness and green-blindness is, according to him, attributable to different colourations of the media of the eye; partly of the yellow spot of the retina, partly of the crystalline lens.

These colourations are chiefly met with in the sick or the very old, and, when occurring in otherwise useful eyes, are not of such strength that they could bring out conspicuous deficiency of brightness in different parts of the spectrum.

The colouration of the yellow spot of the retina takes effect in a very limited but very important part of the field of view, and in only a narrow band of the spectrum. The most trustworthy observations on the influence of the wave-length of the incident light upon the strength of the red and green excitations, have been made with kinds of light not liable to be absorbed in notable degree by the yellow pigment. On the whole, it is accordingly found that this pigmentation is subjectively influential only in cases in which the rays in the neighbourhood of the line F play a prominent part, as, for example, in a certain mixture of this blue with red (mentioned on page 354) which, if it looks white when our eyes are directly fixed upon it, will show blue predominant when we look in a slightly different direction.

As far as hitherto-known facts go, it appears very improbable that Hering's theory of dichromasy can be carried through. Nevertheless, further observations in this direction are very desirable. The influence which the colouration of the yellow spot has in individual eyes can be estimated by comparing the appearances of colour-mixtures in the centre of the field of view with their appearances very near the centre. Such comparisons will show with certainty where such influence is present and where it is absent.

The following is a summary, by Prof. Everett, of two passages from the new edition of Helmholtz's "Physiological Optics," which are important as supplementing the foregoing critique of Hering's theory:—

In discussing the results of experiments for determining the exact positions of the three elementary sensations with respect to actual colours, in Newton's diagram or in Lambert's pyramid, Helmholtz represents the results by a triangle with the three elementary sensations at its corners, and with the colours of the spectrum plotted along a curve which lies entirely in the central portion of the triangle. He says, p. 457:—

"This curve shows that every simple colour excites simultaneously in the trichromic eye the three nerve-elements which are sensitive to light, and excites them with only moderate differences of intensity. If we then hypothetically refer all these excitations to the presence of three photo-chemically alterable substances in the retina, we must conclude that all three of these must have nearly the same limits of sensibility to light, and must show, in the rates of their photo-chemical actions for the different wave-lengths, only secondary variations of moderate amount. Similar variations, arising from the presence of foreign substances, from substitutions of analogous atom-groups, and so on, occur also in other photo-chemically alterable substances as used in photography; for example, in the different haloid salts of silver."

In a mathematical discussion of colour-blindness, commencing at p. 458, he points out that in dichromic vision there must be a linear relation between the three independent elements of trichromic vision, and in Lambert's colour pyramid there must be a certain line through the vertex, such that any plane drawn through it is a plane of uniform colour. Newton's diagram of colour may be regarded as contained in any plane which cuts the axis of the pyramid; and it is very important to determine the point in which the above-mentioned line cuts such a plane; for any line in Newton's diagram that passes through this point is a line of uniform colour to the dichromic vision in question. Experiment shows that it always lies outside the triangle of actual presentable colours.

Addendum.

Prof. Everett adds the following remarks of his own on the present position of the problem of colour-vision:—

On the one hand, it is established, as a fact of experiment, that the excitation of colour-sensation in the normal eye depends upon only three variables, and that their effects are superposable, so as to admit of being expressed by equations of the first degree, otherwise called linear equations. The simplest choice of three variables is that adopted in Young's theory, because it only requires positive values of the variables.

On the other hand, the various colours regarded as subjective appearances do not naturally class themselves under a threefold heading. Yellow does not look as if it consisted of red and green. Colour-sensations as known to us in consciousness are not threefold but manifold.

The two facts taken together seem to imply two successive operations intervening between the incidence of light and the perception of colour. The first operation is threefold, and may consist (as above suggested by Helmholtz) of the photo-chemical decomposition of three different substances. The second operation consists in the effects of the first operation upon a complex organism, and the distinctions of colours as we see them arise out of the nature of this organism.

The number of independent variables required for specifying the condition of a system is a very different thing from the number of well-distinguished states in which the system can exist. For example, the state of a given mass of water-substance is completely determined if its volume and temperature are given, and therefore depends on only two variables. But the number of its well-distinguished states is three. In like manner colour depends on three variables, but the number of well-distinguished colours, besides white, may be said to be seven, namely the six principal colours of the spectrum and purple.

What differences of condition in the organism correspond to these eight distinct appearances in the field of view, and how these different conditions are produced by the three primary excitations, are problems awaiting solution.

AUTOMATIC MERCURIAL AIR-PUMPS.

OF late years, and more especially during the last decade, men of science have devoted much thought and ceaseless energy to the invention of an apparatus which should admit of the automatic working of mercurial air-pumps. Of the numerous inventions brought forward, the ingenious apparatus of Schuller and Stearn are especially deserving of mention.

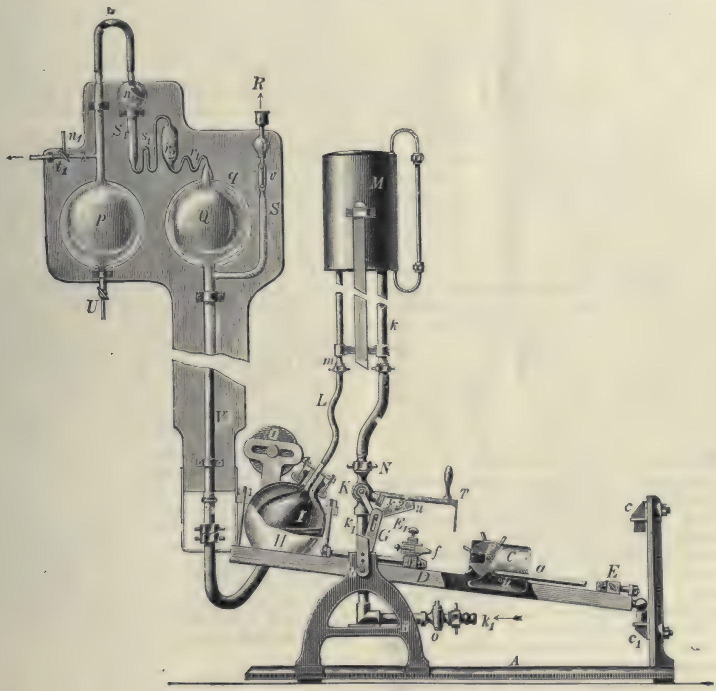
But notwithstanding the present extensive employment of the mercurial air-pump in science as well as in technics these appliances are neither much known, nor have they been used to any great extent, although they are of great importance, and would probably be very advantageous. This may be explained by the fact that they are wanting in the necessary simplicity and trustworthiness, without which the advantages of automatically working mercurial air-pumps are somewhat doubtful.

We shall describe now an apparatus for the perfectly trustworthy and automatic working of mercurial air-pumps, as well as the shape of the glass pump used in connection with it, which, while possessing the greatest possible simplicity, admits of the highest rarefactions hitherto known.

The figure shows the automatic apparatus in connection with an improved Toepler mercurial air-pump. The glass ball H is connected on the one hand by flexible tubes with the pump Q, on the other hand by the tube L with the accumulator M. The water-pipe K runs into the bottom of the accumulator, and by means of a specially-constructed three-way cock K can either be connected with the hydrostatic pressure-pipe K_1 or the discharge-pipe K_2.

If water under pressure is admitted through the tubes k_1, K and k into M, the air contained in M is compressed. This air again exerts a pressure through the tube L on the mercury contained in H, and drives it into the pump Q. As soon as the mercury has risen sufficiently high and the cock K is reversed, the compressed air forces the water out again through k, K, and k_2, and the mercury falls down on account of its own weight out of the pump Q back into the ball H.

The reversing of the three-way cock, and therewith the automatic action of the pump, is effected in the following manner:—The ball H rests on a frame D, revolving about the axis *b*, and the motion of which is limited by the ledges *c* and c_1. A lever G is attached to the frame not far from the axis, and by means of a peg, when the balance D reverses its position, also turns the cock. When the ball H is entirely filled with mercury the balance D rests on the upper ledge *c*. If the pump is set in motion the left side of the balance D becomes lighter in proportion to the amount of mercury forced out of the ball H into the pump, until at last the weight C on the right-hand side becomes heavier, and the balance thereby attains the position shown by the figure. The three-way cock is also reversed by this motion.



Thus, as already described, the water current is now cut off, the water present in M flows out through K_2, and the mercury goes back from the pump Q into the ball H.

During the tipping over of the balance, however, the sliding weight C has run down its inclined plane to a ledge, E, so that it now exerts a pressure on the lever arm. Its momentum is so calculated that the mercury in the pump must have fallen to the point *p*, and flowed back into the ball H before it again overweighted, and moves back the balance. The weight C then slides back again to the left until it rests against its left ledge, and the play of the pump recommences. It will easily be seen that the height to which the mercury rises in the pump, the mass of the sliding weight being a constant quantity, depends only on its final positions, and that, therefore, the adjusting of the height of the mercury can be easily and accurately done up to a centimetre.

It goes without saying that every mercurial air-pump not provided with cocks can be worked by the apparatus just described. But the improved construction of the Toepler pump, drawn likewise in projection in the figure, has proved to be especially practical. The following is a description of its automatic working:—

If the cock t_1 is connected with an hydrostatic air-pump, the ball Q of the pump and the space R, which is to be evacuated through the tube S, is pumped out up to the tension of the vapour. The mercury then rises in the tube R almost to the height of the barometer above its level in the ball H. If the automatic apparatus is then set in motion, the mercury enters the ball Q and the tube S, thus cutting off the connection with R, while any further rising of the mercury in the tube S is prevented by a glass valve *v*, it passes through the first V-tube r_1 filling the little vessel r_2 and rises through s_1 into the ball *n*, driving before it the air which was before shut off in Q. At this moment so much mercury has been forced out of the ball H into the pump Q, that the balance is turned, the mercury flows back out of Q into H, forming vacua in r_2 and Q, as the little mercury-threads remaining in the side-tubes r_1 and s_1 form shut-off valves. As soon as the mercury has fallen below the entrance-point of S into E the pressure in R and Q become equal, the denser air flowing out through S into Q. The time during which Q is connected with R may be determined at will by changing the right ledge of the sliding weight. Then the balance again changes its position, the mercury rises in

V, and so on. When the pump has made a few strokes in this manner, a lever T is let down, so as to rest on the ledge *u*. The wheel F provided with six pegs is now turned a tooth farther each time the weight C slides from the left to the right, and the ledge-peg *f*, which when the lever was raised caught each time into a notch of the peg-wheel, rests for the length of five strokes of the pump against the circumference of the wheel, and does not catch into the notch until the sixth stroke. As the rising of the quicksilver in the pump is in the inverse proportion of the momentum of the counter-weight in its left final position, if the ledges and peg *f* are rightly placed, it will when ascending be driven five times into the little hollow space r_2 and only at the sixth into the ball *n*. In consequence of this the little air-bubbles are accumulated in the highly evacuated space r_1 in which they ascend owing to the slight counter-pressure, and forming larger bubbles, and having easily overcome the somewhat greater counter-pressure of the mercury column s_1 they rise into the ball P.

All these manipulations are performed *entirely automatically* by the apparatus. At the same time that the toothed wheel has commenced working (*i.e.* when the volume of air pumped out by the pump has sufficiently diminished) the vessel P is entirely cut off from the hydrostatic air-pump by the cock t_1, thus ceasing to act. The mercury of the pump is entirely shut off on *both sides* from the exterior air, and only in contact with perfectly *dry* air. After stopping the pump, concentrated sulphuric acid may be sucked up into P, which dries up entirely. The mercury is shut off from M by a caoutchouc bag, I.

The following experiments were made at the Physical Institute of the University of Berlin:

400 c.cm. (cubic centimetres) were evacuated to 1/1000 m.m. in ten minutes; 4000 c.cm. = 4 litres, in an hour.

The highest rarefaction hitherto obtained has been about from 1/6000,00 – 1/800,000 m.m. = to about $\frac{1}{430000000} - \frac{1}{600000000}$ atmospheres.

The pump is supplied by Messrs. E. Leybolds Nachfolger, Cologne (Germany). AUGUST RAPS.

CRYSTALLISED CARBON.

In the course of some researches on the properties and modes of formation of the various forms of carbon, M. Henri Moissan has succeeded in reproducing the variety of diamond known as *carbonado*, or black diamond, and has even obtained some minute crystals of the colourless gem. An account of his results in the *Comptes Rendus* of February 6 is followed by an article on the reproduction of the diamond, by M. Friedel, and some congratulatory remarks by M. Berthelot.

As long ago as 1880 Mr. Hannay[1] indicated the formation of diamond-like crystals on heating under high pressure, in a tube of iron, a mixture of lithium, lampblack, essence of paraffin, and bone oil. It was then supposed that the nitrogenous compounds of the last substance played the most important part. In M. Moissan's new process carbon obtained from sugar is dissolved in a mass of iron, and allowed to crystallise out under high pressure. To produce this pressure the expansion of iron during condensation is utilised. The carbon is strongly compressed in an iron cylinder closed with a screw-stopper of the same metal. A quantity of soft iron, weighing about 150 or 200 gr., is melted in the electric furnace in a few minutes, and the cylinder is plunged into the molten mass. The crucible is at once taken out of the furnace and splashed over with water. When the external crust is at a red heat the whole is allowed to cool slowly in air.

The metallic mass thus obtained is attacked by boiling hydrochloric acid until all the iron is removed. There remain three forms of carbon: graphite in small quantity; a chestnut-coloured carbon in very small needles, such as has been found in the Cañon Diablo meteorite; and a small quantity of denser carbon which has to be further isolated. For this purpose the mixture is treated alternately with boiling sulphuric and hydrofluoric acids, and the residue decanted in sulphuric acid of density 1·8. It then contains only very little graphite, and various forms of carbon. After six or eight treatments with potassium chlorate and fuming nitric acid, the residue is boiled in hydrofluoric acid and decanted in boiling sulphuric acid to destroy the fluorides. It is then washed and dried, and bromoform is employed to separate out some very small fragments denser than that liquid, which scratch the ruby, and, when heated in oxygen at 1000°, disappear.

Some of these fragments are black, others transparent. The former have a rough surface, and a greyish black tint identical with that of certain carbonadoes; they scratch the ruby, and their density ranges from 3 to 3·5. Some pieces have a smooth surface, a darker colour, and curved edges. The transparent fragments, which appear broken up into small pieces, have a fatty lustre, are highly refractive, and exhibit a certain number of parallel striæ and triangular impressions.

During combustion in a current of oxygen at 1050°, some of the fragments left cinders of an ochreous colour, usually preserving the original form of the small crystal—just as in the combustion of impure diamonds.

As indicated already by Mr. Sidney Marsden,[1] silver heated to 1500° in presence of sugar carbon is found to contain on cooling some black crystals with curved edges. M. Moissan has found that high pressure is indispensable. He heated silver till it boiled briskly in contact with carbon, and found that a certain quantity of the latter was dissolved. By suddenly cooling in water, a portion of liquid silver, cooling inside a solid crust, was subjected to a very high pressure. No diamonds were formed, but rather a large crop of carbonadoes of densities ranging from 2·5 to 3·5, thus forming a series connecting graphite with diamond. Bromoform separated a carbonado, which scratched the ruby and burned in oxygen at 1000°. A quantitative determination of this reaction showed that 0·006 parts of this substance gave 0·023 of carbonic acid.

M. C. Friedel describes an experiment in which he obtained a black powder capable of scratching corundum by the action of sulphur on molten iron containing 4 per cent. of carbon. But the question of the production of diamond powder by this means is as yet an open one.

M. Moissan is continuing his researches on the solubility of carbon in iron, silver, and their alloys. It is to be hoped that he will soon be able to exhibit artificial true diamonds of a more imposing size.

LINES OF STRUCTURE IN THE WINNEBAGO CO. METEORITES AND IN OTHER METEORITES.[2]

The ground and polished surface of a Winnebago Co. meteorite showed to me some interesting markings. Subsequent examination revealed like markings in other meteorites. Perhaps these markings have been described. If so I have no recollection of the description, and therefore it seems worth while to call attention to them.

The polished surface of a small Winnebago stone, three or four square centimetres in area shows several hundreds of bright metallic points. The larger iron particles in this surface have great varieties of shapes—the smaller ones are usually mere points. When seen with a lens, or even at a distance from the eye suited to distinct vision there does not appear to be any regular structure or arrangement of the bright points. But if the surface is so held as to be a little beyond the place of distinct vision, and at the same time, turned around in such a way as to reflect always a strong light to the eye, either skylight or lamplight, there appear lines of points across the polished surface of the stone, which suggest very strongly the Widmanstaetten figures on metallic meteorites. At times, as the stone is turned, no lines can be detected. Again one set of parallel lines or two sets crossing each other become visible. Some of the sets are very sharply manifested, and some are so faint as to leave one in doubt whether the lines are real or only fancied. There are on the surface in question six or eight of these sets of lines.

[1] Proc. Roy. Soc. Ed. 1880, vol. ii. p. 20.

[2] Reprinted from the February number of the *American Journal of Science*.

A second surface was ground nearly parallel to the first, at about one centimetre distant from it, and like lines appeared on this parallel surface. Some of the lines, but not all of them, corresponded in direction in the two surfaces. Four more surfaces approximately at right angles to the first surface, and corresponding to the faces of a right prism, were then ground, and upon these surfaces the like sets of lines appear with more or less distinctness.

A slab of a Pultusk stone 6 × 7 centimetres shows over its entire surface like markings. Something like a curvature of the lines appears in one instance, but in general the lines run straight from side to side of the slab. The slab is six millimeters in thickness, and most of the sets of lines have the same directions upon the two sides.

A Hessle stone, a small slice from the Wold Cottage stone, one from Sierra di Chaco, one from a Sienna stone, a fragment from the Rockwood stone, and a slice from the Rensselaer Co. stone, all show with more or less clearness the like markings. Of three microscope slides of the Fayette Co. meteorite one shows them clearly, a second shows traces of them, the third not at all.

A considerable number of the ground surfaces of meteoric stones in the Peabody Museum also show these markings. For example, a triangular surface of a Weston stone, 8 or 10 centimetres to each side, exhibits them very well.

These markings are such as we might expect if the forces which determine the crystallisation of the nickel-iron of the iron meteorites also dominated the structure of the rock-like formations of the stony meteorites and the distribution therein of the iron particles. The relation of quartz crystals to the structure of graphic granite is naturally suggested by these meteorite markings.

H. A. Newton.

THE LATE THOMAS DAVIES, F.G.S.

Mr. THOMAS DAVIES, who died on December 21 last, was born on December 29, 1837, in the neighbourhood of London, and was the son of Mr. William Davies, F.G.S., of the Geological Department of the British Museum. His early education was of a very elementary character, and the period of his school-life was brief: finding town-life irksome, and yearning for freedom and adventure, he took to the sea at the age of fourteen, and during the next four years led a roving life, visiting China, India, and various parts of South America. He was then prevailed upon by his father to adopt a more settled mode of existence, and on the separation of the Department of Mineralogy from that of Geology was appointed in 1858 a third-class attendant at the British Museum under Prof. Maskelyne, to whom the care of the minerals had been assigned; in the following year he added to his responsibilities by marriage.

During the next nine years, save for a short interval when Dr. Viktor von Lang was an assistant in the Department, Mr. Davies was the sole helper of Mr. Maskelyne in the arrangement and examination of the mineral collections; during this time Mr. Maskelyne effected a thorough change in the classification and arrangement of the minerals, and in labelling with localities the large number of specimens that were without any descriptions except what could be traced out in old catalogues. In this work, and in the cleaning and arranging some tons of specimens, of which many were entirely valueless, the patient and intelligent aid of "young Davies" alone rendered it possible to carry out the preliminary operations. As the collection grew into orderly arrangement, the registration and labelling of specimens was entrusted to him by Mr. Maskelyne. It was thus that he gradually acquired an eye-knowledge of minerals which has rarely, if ever, been surpassed. His perception of the peculiarities of a specimen was remarkably quick, while his remembrance of individual specimens was almost marvellous. It was particularly in the habit, the locality, the associations and modes of occurrence of mineral species that he concentrated his interest; and to his knowledge in this direction his earlier training, under the eye of Mr. Maskelyne, in the labelling of the minerals, accumulated in the cases and drawers of the collection, very largely contributed.

In the early years of Mr. Davies's museum life Mr. Maskelyne was further engaged in the study of thin sections of meteorites, and initiated Mr. Davies into a knowledge of the microscopic characters of rock-forming minerals, a mode of investigation then almost unknown. In this direction his quickness of perception and excellence of memory had full scope for play, and Mr. Davies soon became extremely skilful in the microscopic determination of minerals in rock-sections, and in the recognition of peculiarities of rock-structure. Few practical petrologists approached him in this faculty.

Nor did he neglect to improve his general education. With this end in view he attended the evening classes at the Working Men's College in Great Ormond Street, and in the course of time acquired a knowledge of both French and German. He was also familiar with plants and fossils, a knowledge largely derived from his father.

His remarkable qualifications attracted the early attention of Mr. Maskelyne, and in 1862 were officially recognised in his promotion by the trustees from the grade of attendant to that of transcriber or junior assistant. In 1880 he was promoted to the grade of first-class assistant. By a remarkable coincidence his father, Mr. William Davies, who had long been renowned for his large practical knowledge of important branches of palæontology, and especially of fossil fishes, and had likewise begun museum life as an attendant, obtained the same promotion on the same day. In the same year Mr. Davies was awarded the balance of the proceeds of the Wollaston Fund by the Council of the Geological Society as a testimony of the value of his researches in mineralogy and lithology. Still later, in 1889, the name of *Daviesite* was given to a new mineral "in honour of Mr. Thomas Davies, who has now been associated during upwards of thirty years with the British Museum Mineral Collection, and whose mineralogical experience and Breithauptian eye have ever been willingly placed at the service, not only of his colleagues, but of every one who has been brought into relationship with him."

He became a Fellow of the Geological Society in 1870, and was an early member of the Mineralogical Society of France.

His published work was not voluminous; it relates almost exclusively to the microscopic characters of the pre-Cambrian rocks. He contributed, however, the bulk of the articles on mineralogy and petrology for "Cassell's Encyclopædic Dictionary," and for some years edited the *Mineralogical Magazine*.

Mr. Maskelyne, for whom he was right-hand man, and almost sole working helper during upwards of twenty years, looks back with fond regret on the uninterrupted happiness of their association. According to my own experience of the last fifteen years, he was an excellent colleague, always cheerful, good-tempered, and kind-hearted, ever ready to help in any direction, however much it might interfere with the particular work he had immediately in hand. At home he was an enthusiastic gardener; wet or fine, absolutely reckless of weather, he was at work from early sunrise, and could boast the possession of one of the best managed gardens in the neighbourhood. His love of fresh air and the bustling east wind never left him; even after recovery from the long illness which two years ago had taken him to the verge of the grave, he did not hesitate to show the greatest contempt for the protection of an umbrella, and notwithstanding the remonstrances of his friends, might still be occasionally seen enjoying the beating of the wind and rain on his unprotected face.

He was an Original Member of the Mineralogical Society, and Foreign Secretary for several years preceding his death.

Mr. Davies leaves a widow and nine children to mourn his loss. L. FLETCHER.

NOTES.

AT the last meeting of the Council of the Mineralogical Society, it was resolved to initiate a "Thomas Davies Memorial Fund" on behalf of the widow and children of the late Mr. Thomas Davies, F.G.S., of the British Museum. The following gentlemen have consented to act as an Executive Committee:—Prof. N. S. Maskelyne, F.R.S. (chairman), Dr. Hugo Müller, F.R.S. (treasurer), Mr. H. A. Miers, F.G.S. (secretary), Prof. T. G. Bonney, F.R.S., Mr. L. Fletcher, F.R.S., Dr. Henry Hicks, F.R.S., W. H. Hudleston, F.R.S., Prof. J. W. Judd, F.R.S., Mr. F. W. Rudler, F.G.S., Mr. F. Rutley, F.G.S., Rev. Prof. T. Wiltshire, F.G.S., Dr. Henry Woodward, F.R.S. Subscriptions for the fund should be sent to Dr. Hugo Müller, 13 Park Square East, Regent's Park, London, N.W.

AN extra meeting of the Chemical Society will be held on February 20, at 8 p.m., the anniversary of the death of Herman Kopp, when a lecture will be delivered by Prof. T. E. Thorpe, F.R.S. Lord Playfair will be in the chair.

AN International Botanical Congress is to be held during the Columbian Exposition at Chicago. Prof. C. E. Bessey will receive communications on the subject.

M. P. DUCHARTIE has been elected president, and M. L. Guignard first vice-president, of the Botanical Society of France for the year 1893.

THE annual public meeting of the University College Chemical and Physical Society will be held at University College, Gower Street, on Friday, February 24. The chair will be taken at eight o'clock by Prof. F. T. Roberts, and Prof. Watson-Smith will deliver an address on diseases incident to work-people in chemical and other industries.

MR. THOMAS BRYANT, president of the Royal College of Surgeons, delivered the Hunterian oration on Tuesday afternoon in the theatre of the college, in the presence of the Prince of Wales and the Duke of York and a large and distinguished company. Mr. Bryant began by thanking their Royal Highnesses for their presence on the special occasion of the centenary of the death of John Hunter, the great founder of scientific surgery. In the course of his oration Mr. Bryant said that the whole world of vegetable and animal life was Hunter's subject, but that his main objects were the improvement of surgery by the elucidation of pathology; the examination of the causes which determine any departure from the normal type, whether of form or function; and the study of the means which nature adopts for the healing of wounds and the repair of injuries. It was one of his special merits that he raised surgery out of the position of a a poor art, based on empirical knowledge and practised too much as a trade, to establish it firmly as a high and elevating science, at the same time raising its practitioners in the social scale, and doing as much for medicine as for surgery, for he considered them inseparable. He made the profession scientific by basing it upon the widest knowledge of the structure and functions of all living things, and educed therefrom laws and principles for the guidance of future generations in their study and treatment of disease in any of its forms. This alone should render him worthy of the thanks of civilised mankind.

MR. GEORGE MATHEWS WHIPPLE, whose death we briefly recorded last week, had done much solid and valuable work in various departments of physical science. Among the subjects in which he was especially interested were wind force and wind velocities, and throughout the greater part of his life, as the *Times* has said in a brief sketch of his career, he was constantly carrying on experiments with a view to determine wind force and to find out what were the best instruments for securing accurate results. He improved the Kew pattern magnetic instruments; he designed, among other instruments, the apparatus for testing the dark shades of sextants; and at various periods he was associated with Captain Heaviside, Major Herschel, and General Walker, in carrying on pendulum experiments for the determination of the force of gravity. The magnetic part of the report of the committee appointed by the Royal Society to investigate the Krakatoa eruption and the subsequent phenomena was prepared by Mr. Whipple, and valuable papers were from time to time submitted by him to the Royal Society and the Royal Meteorological Society. He was fifty years of age at the time of his death. He entered the Kew Observatory in 1858, became magnetic assistant in 1862, and was appointed superintendent in 1876. This office is one of great and growing importance, and we trust that a capable successor may be found. The Kew Observatory is the central standardising station of the Meteorological Office, and numerous magnetical observatories in other countries are similarly connected with it. New instruments are tested there, and experiments are made, and it has now grown into an institution where the verification of scientific instruments of many kinds, including thermometers, sextants, telescopes, watches, and recently photographic lenses, is carried on on a large scale, as described in the annual report of the Kew committee to the Royal Society.

THE Rev. F. O. Morris died at Nunburnholme, in Yorkshire, on Friday last, at the age of eighty-two. He was well-known as a popular writer on science, and did much to create and foster interest in some branches of natural history, especially in ornithology. Among his many books were "A History of British Birds," issued in six volumes from 1851 to 1857, and his "Natural History of the Nests and Eggs of British Birds," published in three volumes in 1853. In 1854 he was presented to the rectory of Nunburnholme, which he continued to hold until his death.

A DESTRUCTIVE earthquake has taken place in the island of Samothrace. All the buildings are said to have been destroyed. Renewed shocks, accompanied by loud subterranean rumblings, have also occurred at Zante.

ON Sunday a shock of earthquake was experienced in New Zealand. It caused little damage, but was felt in both the North and South Islands, being most severe at Wellington and at Nelson.

THE weather of the past week has been very stormy and damp in most parts of these islands; scarcely a day has passed without gales being reported. On Friday, the 10th, the wind force was especially strong, on the north-east coast of Scotland and in the English Channel, and on Tuesday another deep depression had reached our northern coasts from off the Atlantic, accompanied by strong gales. The United Kingdom was situated between two areas of high barometer readings, one of which lay over Scandinavia and the other over France and Spain. With this distribution of pressure, the conditions were favourable to the passage of cyclonic disturbances within our area, and although the storms were not of exceptional violence in the southern districts, they were so relatively, as the winds have been peculiarly quiet during the last twelve months. Temperature has been a little above the mean for the season, the daily maxima often exceeding 50°, but on Sunday the highest day readings were below 40° over the north-east of England, while a sharp frost occurred in the north of Scotland, the minimum temperature registering 20°. On the continent the temperature has been much lower than in this country; at Haparanda, at the north of the Gulf of Bothnia, which lies in the area of the high barometric pressure over Scandinavia, a temperature of minus 37° was recorded on Friday and Saturday. Rainfall has been of daily occurrence at most stations, although the amounts measured have generally been light, while hail and sleet have occurred in many places. With Tuesday's storm, however, the rainfall exceeded an inch on the west coasts of Ireland and Scotland. By the *Weekly Weather Report* of the 11th instant it appears that the rainfall for that week was greatly in excess of the mean in the north and west of Scotland, and to a less extent in the east of Scotland, the north of Ireland, and the western parts of England. Bright sunshine exceeded the mean in all districts, the greatest amounts, 32 to 38 per cent., being recorded in most parts of England.

THE recent numbers of *Ciel et Terre* (Nos 21–23) contain interesting articles on ozone. The observation of this element by meteorologists has been almost given up in most countries, owing chiefly to the difficulty of obtaining comparable results by the methods at present in use, although its importance for invalids and others as a purifier of the atmosphere is generally acknowledged. And at a recent meeting of the Royal Meteorological Society, regret was expressed at the discontinuance of these observations. D. A. Van Bastelaer, in conjunction with the Royal Observatory of Brussels, maintained a system of ozone observations at 150 of the stations belonging to the Society of Public Medicine in Belgium during the years 1886–91, which is probably the most complete investigation into the subject which has been made. The values found for the various stations are given in a tabular form, and M. Van Bastelaer found that there are continual and sudden variations in the records from hour to hour, between morning and evening, and from one day to another, but that the mean values for any locality remain nearly constant. Isolated values are of no use; a long series of observations is necessary for any results of importance to be arrived at. The air at stations near the sea coast contained, as is usually supposed, the greatest amount of ozone.

THE Indiana Academy of Science lately held at Indianopolis its eighth annual meeting, the president being Prof. J. L. Campbell, of Wabash College, Crawfordsville, Ind. There was a large attendance, and no fewer than ninety-two papers had been prepared, most of which were read. The first volume of the Academy's Proceedings was distributed at the meeting.

THE *Kew Bulletin* continues, in the January number, its series of articles on the food grains of India, one of the subjects being Kangra Buckwheat (*Fagopyrum tataricum*, Gærtn., var. *himalaica*, Batalin). The typical plant is cultivated throughout the higher Himalayas, but more especially on the western extremity, and at altitudes from 8000 to 14,000 feet. The yield in India cannot yet be estimated, but the *Bulletin* says there can be little doubt that the seeds are singularly rich in nutrient constituents. This is confirmed by the conclusions of Prof. Church with regard to a sample he has examined.

THE January number of the *Kew Bulletin* contains also the fourth decade of new orchids, the fourth of "Decades Kewenses," papers on fruit growing at the Cape and the clove industry of Zanzibar, and miscellaneous notes.

PROF. R. SHIMEK is now investigating the flora and the geology of Nicaragua, along the route of the canal, under commission from the State University of Iowa. Dr. Terracciano, of Rome, is about to renew his investigation of the flora of Erythrea, the Italian colony on the Red Sea. Dr. K. N. Denkenbach is commissioned by the Natural History Society of St. Petersburg to investigate the flora of the Black Sea.

MR. R. THAXTER proposes in the *Botanical Gazette* the establishment of a new order of Schizomycetes, the Myxobacteriaceæ, somewhat intermediate in its characters between the typical Schizomycetes and the Myxomycetes. It comprises the genus Chondromyces, placed by Berkeley, in his "Introduction to Cryptogamic Botany," under the Stilbacei, and two new genera, Myxobacter and Myxococcus. The order consists of mobile rod-like organisms, multiplying by fission, secreting a gelatinous base, and forming pseudo-plasmode-like aggregations before passing into a more or less highly-developed cyst-producing resting state, in which the rods may become encysted in groups without modification, or may be converted into spore-masses.

AT the meeting of the Royal Botanic Society on Saturday, one of the branches of the flowering stalk of *Fourcroya selloa* was shown from the Society's conservatory. This is a Mexican plant allied to the aloes, and like them it flowers only once during its life. The plant, which has been in the conservatory for upwards of twenty years, late last autumn threw up a flower spike which in a very short time grew to a height of 30 feet, and, passing through the glass roof, rose for some feet into the open air. It could not, of course, resist the frosts and fogs of winter. The flower-buds dropped unopened, when immediately from each node a number of young plants appeared. This mode of reproduction is found in only a few varieties of plants, and is especially valuable in relation to the cultivation of Fourcroyas as a source of commercial vegetable fibre.

THE Newcastle Literary and Philosophical Society will have no very pleasant associations with the memory of its hundredth anniversary, which was celebrated on Tuesday of last week. During the following night the society's premises caught fire and were greatly damaged. Much injury was done to the library, where many most valuable books were destroyed.

THE fifth and sixth parts of the fifth volume of the *Internationales Archiv für Ethnographie* have been issued together in a single number. It includes the second part of Dr. W. Svoboda's interesting study (in German) of the inhabitants of the Nicobar Islands; a paper (in French) by Désiré Pector on the volume by Dr. Hyades and Dr. Deniker (noticed some time ago in NATURE) on the ethnography of a part of Tierra del Fuego; a suggestive essay (in German) by Dr. T. Achelis, on the psychological importance of ethnology; and the second part of Dr. Schmeltz's careful contributions (in German) to the ethnography of Borneo. The first and last of these papers are admirably illustrated. A valuable paper on the Ainos, by David MacRitchie, of Edinburgh, has been published as a supplement to the fourth volume of the *Archiv*. This paper is accompanied by, and contains full descriptions of, a series of coloured reproductions of most interesting pictures of Aino life by Japanese artists, who have naturally a keener perception of the characteristics of their savage neighbours than can be attained by Western visitors. Mr. MacRitchie seeks to show that the Ainos display "unmistakable traces of a near descent, by at least one line of their ancestry, from the most crude form of humanity."

MESSRS. SAMSON AND WALLIN, Stockholm, are about to issue what promises to be an important and interesting work, by F. R. Martin, on the Siberian Antiquities of the Bronze Age, preserved in the museum of Minousinsk. Nearly 900 objects in copper and bronze will be represented in the plates, which, according to the prospectus, are being prepared with the greatest care. The antiquities of which these objects are selected specimens were collected in 1874 by M. Nicolaï Martianow from mounds in the steppes of the Upper Yenisei. They are the finest provincial collection in the Russian Empire, and M. Martin found much to interest him in classifying and photographing them. The present volume will be the first of a series of works on the ethnography and archæology of Western Siberia by the same writer.

THE third volume of "A Journal of American Ethnology and Archæology," edited by J. Walter Fewkes, has been issued. It contains an interesting "outline of the documentary history of the Zuñi tribe," by A. F. Bandelier, and "somatological observations on Indians of the south-west," by Dr. H. F. C. Ten Kate. It is worth while to note that in Dr. Ten Kate's opinion the study of physical anthropology among the North American Indians does not tend to demonstrate that their types are exclusively American. It rather shows, he thinks, that they present only the characteristics of "the Mongolian or so-called yellow races." "I do not mean," he says, "that the American aborigines are Mongolians in the strict sense of the word, or that America has been populated from Asia. Where the Indians came from I do not know, but my position is as follows :—The American race is, somatologically speaking, not a type, but has characteristics which can only be called Mongoloid."

PROBABLY no living sportsman has shot more big game in South Africa than Mr. F. C. Selous, who for years was more at home in a waggon or a tent somewhere in the far countries of Africanderland than in the towns and settlements of the Cape Colony or the Transvaal. He has nearly completed an account of eleven years' sport and travel, which will be shortly published by Messrs. Rowland, Ward and Co., of Piccadilly. It will be fully illustrated, and will include a variety of general information on subjects of interest in connection with the latest developments of South African exploration.

MR. ELLIOT STOCK has published the third volume of "The Field Club," a magazine of general natural history for scientific and unscientific readers, edited by the Rev. Theodore Wood. The volume contains many articles which are well fitted to awaken interest in various aspects of natural science.

WE referred lately to Dr. D. G. Brinton's opinion as to the relation between nervous diseases and civilisation. As his view has been called in question by Dr. Rockwell, he returns to the subject in *Science*, supporting his own conclusions by a reference to a paper contributed by Dr. I. C. Rosse, professor of nervous diseases at the Georgia Medical College, to the *Journal of Nervous and Mental Disease* for July, 1891. In this paper Dr Rosse cites many authorities to prove that there is as much nervous disease at low as at higher stages of civilisation, and perhaps more. In the district of Columbia, for example, the decedents among the coloured people from nervous diseases often exceed those of the white population by thirty-three per cent. Dr. Rosse is inclined to believe that a sudden change in the social habits and condition of any race, at any stage of advancement, will result in a prompt development of neurotic disease. A high civilisation, which is stable, excites such a condition less than instability in lower grades.

AT the meeting of the Field Naturalists' Club of Victoria in November a paper presenting a list of species of Victorian butterflies was communicated. It had been prepared by Messrs. F. Spry and Ernest Anderson, and embodied the results of work carried on during many years. The *Victorian Naturalist* says the paper was "received with great satisfaction, and will prove of extreme value to the Victorian lepidopterist."

MR. H. L. CLARK records in *Science* what he calls "a bit of satisfactory evidence" as to the rate of speed in the flight of certain birds. He thinks that this is often greatly exaggerated. He was travelling lately on the Baltimore and Ohio Railway, up the valley of the Potomac, when he saw a great many wild ducks, which are admitted to be among the strongest flyers in America. It so happened that, on rounding a sharp curve, the train flushed a pair of buffle-heads, which started up stream at full speed. On watching them he found that, instead of their leaving the train behind, the train was actually beating them, and he is confident that their rate of speed was not equal to that of the train. "We kept alongside of them," he says, "for nearly a minute before they turned back down-stream. Careful calculation showed that the train was running at about thirty-seven miles per hour, so that the rate of speed for those wild ducks would be about thirty-six. I hope that others may have some evidence on this question of speed in flight which will throw more light on the subject."

AN interesting illustration of the tendency of inorganic matter to simulate the forms seen in organic is afforded by some specimens of hæmatite from a mine in Lake Superior district. It is described in the *American Geologist* as a fibrous red hæmatite, compact and tough-looking, and the radiating filaments or fibres towards their summits are seen to spread out like some frondescent vegetable growths. It would seem that in process of increase these fibres, starting from different but slightly distant points, and having a tendency to expand, soon began to interfere with one another. The line of contact, which became a plane as growth continued, is marked by a more or less distinct plane of separation. This frondescent hæmatite, in addition, is pierced by a number of peculiar channels which seem to date from the time of development of the crystals. It is noticed that these run, in general, perpendicular to the fibrous structure, and lie in or across the planes of contact of two oppositely spreading frondescent growths. These appear to mark in the first instance the vacancies left by the first contacts of overarching growths from opposite directions. These branches then interfered with the free circulation of air, and interrupted and permanently stopped the development of these fibres beneath the overspreading canopy.

IT was shown by Ferraris some time ago (and the fact was of great practical importance) that by means of two simple alternating currents acting in fixed spirals, a rotating magnetic field could be produced, which by inductive action set in rotation a copper cylinder or other conducting body brought into the field. Also an iron cyclinder, cut through so that the Foucault induction currents could not be formed, was rotated by virtue of so-called magnetic hysteresis. Further studies in this direction have been made by Signor Arno, using electric instead of magnetic forces, and a dielectric body instead of a magnetic.

He thus succeeded in rotating a hollow cylinder of mica, or other insulating substance, hung by a silk fibre, in the space enclosed by four vertical curved copper plates, to which the requisite differences of potential were communicated. An account of these interesting experiments (described to the Accademia dei Lincei) will be found in the *Naturwissenschaftliche Rundschau*, No. 3, 1893.

PROF. R. C. SCHIEDT has been making some interesting observations on oysters, and at a recent meeting of the Philadelphia Academy of Natural Sciences Prof. Ryder reported on his behalf that oysters which had the right valve removed and were exposed to the light in this condition, in a living state for a fortnight or so, developed pigment over the whole of the epidermis of the exposed right mantle and on the upper exposed sides of the gills, so that the whole animal from this cause assumed a dark-brown colour. Animals so exposed not only attempted to reproduce the lost valve and hinge, but also partly succeeded in so doing, even re-establishing the insertion of the diminutive pedal muscle upon the inner face of the imperfectly reproduced right valve, which was deformed owing to the lack of support of the right mantle, because of the removal of the original right valve. As a consequence the right mantle was rolled up at the edge, and this deformation of the mantle was reflected in the attempted regeneration of the lost right valve. The pigment developed during exposure to light in the mantle and gills in oysters with the right valve removed, which were kept alive in the aquaria at Sea Isle City by Prof. Schiedt, was wholly confined to the epidermis as it normally is at the mantle border in the unmutilated animal in nature. The inference to be drawn from these facts is that the development of pigment in the mantle and gills was wholly and directly due to the abnormal and general stimulus of light over the exposed surface of the mantle and gills, due to removal of the right valve, and that the mantle border, the only pigmented portion of the animal, is pigmented because it is the only portion of the animal which is normally and constantly subjected to the stimulus of light.

MR. D. CLEVELAND, of San Diego, California, contributes to *Science* an article in which he states some curious facts regarding the trap-door spider (*Mygale henzii*, Girard), which is widely diffused in California. Behind San Diego there are many hillocks about a foot in height and three or four feet in diameter. These hillocks are selected by the spiders, Mr. Cleveland suggests, because they afford excellent drainage and cannot be washed away by the winter rains. A suitable spot, which always consists of clay, adobe or stiff soil, having been chosen, the spider excavates a shaft varying from five to twelve inches in depth, and from one-half to one and a half inches in diameter. This is done by means of the sharp horns at the end of the spider's mandibles, which are its pick and shovel and mining tools. The earth is held between the mandibles and carried to the surface. When the shaft is of the required size, the spider smooths and glazes the wall with a fluid which is secreted by itself. Then the whole shaft is covered with a silken paper lining, spun from the animal's spinnarets. The door at the top of the shaft is made of several alternate layers of silk and earth, and is supplied with an elastic and ingenious hinge, and fits closely in a groove around the rim of the tube. This door simulates the surface on which it lies, and is distinguishable from it only by a careful scrutiny. The spider even glues earth and bits of small plants on the upper side of the trap-door, thus making it closely resemble the surrounding surface. The spider generally stations itself at the bottom of the tube. When, by tapping on the door, or by other means, a gentle vibration is caused, the spider runs to the top of its nest, raises the lid, and looks out and reconnoitres. If a small creature is seen, it is seized and devoured. If the invader is more formidable, the door is quickly closed, seized, and held down by the spider, so that much force is required to open it. Then the spider drops to the bottom of the shaft. When the door of the nest is removed, the spider can renew it five times—never more than that. From forty to fifty cream-coloured spiderlings are hatched from the yellow eggs at the bottom of the nest. When these have attained only a fraction of their full size—before they are half grown—the mother drives them out into the world to shift for themselves. After a brief period of uncertainty they begin active life by making nests, each for itself, generally close to "the old homestead," sometimes within a few inches of it. These nests are always shallow and slender, and are soon outgrown. When the spider attains its full size it constructs a larger nest.

AN interesting paper concerning the supposed volatility of the element manganese is contributed by Prof. Lorenz and Dr. Heusler, of Göttingen, to the current number of the *Zeitschrift für Anorganische Chemie*. Although the melting point of the metal is known with tolerable certainty to be about 1800°—1900°, much higher than that of iron, no information has yet been acquired concerning its boiling point. Profs. Lockyer and Chandler Roberts, however, so long ago as 1875 pointed out that the metal was volatile at the temperature of the oxyhydrogen blowpipe; and M. Jordan, in a communication to the *Comptes Rendus* in the year 1878, reported that in the manufacture of highly manganiferous spiegeleisen near Marseilles, a deposit very rich in manganese was usually found in the cooler portions of the furnace. Moreover, M. Jordan stated that during the casting of ferro-manganese red flames are produced, from which a heavy fume is deposited containing a large percentage of manganese. M. Jordan subsequently heated ferro-manganese to a white heat in a crucible in his laboratory, and ascertained that a diminution in the percentage of manganese actually occurred. These observations were considered somewhat surprising, inasmuch as the melting point of manganese is so high, in the neighbourhood of white heat, and it would appear that this volatility must be exhibited even at the melting point itself.

PROF. LORENZ and his colleague have therefore conducted a series of experiments with the view of ascertaining whether manganese is really volatile *per se*, or whether the volatility is due to the intermediate action of carbon monoxide (derived from the carbon usually present) in forming a volatile but dissociable compound of a nature similar to nickel- and iron-carbonyl. It was first definitely proved that carbon monoxide does not combine with manganese below the temperature of 350°, a fact which M. Guntz has recently independently pointed out. Experiments were then made at higher temperatures, using a new form of combustion furnace, designed by Prof. Lorenz and fully described in the *Zeitschrift*, in which each individual burner is supplied with a blast capable of being regulated, the whole apparatus being equivalent to a row of blowpipes which will rapidly raise a thick porcelain tube up to a white heat. In the first series of these high temperature experiments coarsely powdered manganese containing seven per cent. of carbon was heated to whiteness in a glazed porcelain tube in a current of carbon dioxide, in order that nascent carbon monoxide might be produced in contact with manganese by the reduction of the carbon dioxide by the carbon present. After half-an-hour's heating the tube was allowed to cool in the stream of carbon dioxide and then broken, when it was found that a large quantity of the manganese had volatilised and condensed again further along the tube, in the form of a thick black deposit somewhat resembling zinc dust. Upon repeating the experiment with a current of carbon monoxide, a similar result was obtained. Hence manganese is certainly volatile in carbon monoxide. But it was afterwards found that equally good deposits of manganese dust were obtained when a current of either hydrogen or nitrogen, neither of which combine with manganese, were employed. It is therefore evident that manganese does not resemble iron and nickel in forming a volatile compound with carbon monoxide, but that the volatility is a property of the element itself, and is singularly manifested even at the temperature of the melting point.

SOME of the more interesting captures recently made by the dredging staff of the Marine Biological Association at Plymouth are the Actinian *Chitonactis coronata;* the Nudibranchs *Berghia cœrulescens* (new to Britain), *Amphorina cœrulea*, and *Lamellidoris oblonga* in considerable numbers; and the handsomely marked rare spider-crab, *Stenorhynchus egyptius.* The alga *Halosphæra viridis* has been present in all townettings since October; and *Noctiluca*, though in small numbers, is now generally present. The breeding season of a large number of Invertebrata has already commenced, and the sea swarms with Copepod and Cirrhipede Nauplii, and with Polychæte larvæ. Species of the following genera are breeding:—The Hydroids *Halecium, Plumularia, Sertularella, Hydrallmania;* the Actinians *Chitonactis* and *Actinia;* the Nemertine *Lineus obscurus* (larva of Desor); *Phyllodoce maculata* and other Annelids; the Molluscs *Capulus hungaricus, Lamellaria, Buccinum, Purpura,* many Nudibranchs; and the Decapod Crustacea *Crangon, Pandalus,* and *Palæmon; Carcinus, Cancer,* and *Eurynome.*

THE additions to the Zoological Society's Gardens during the past week include a Fallow Deer (*Dama vulgaris* ♂) European, presented by Mr. B. L. Rose; a Great Eagle Owl (*Bubo maximus*) European, presented by Mr. Adolphus Drucker; two Gold Pheasants (*Thaumalea picta* ♀ ♀) from China, presented by Miss Forster; nine Snow Buntings (*Plectrophanes nivalis*) British, presented by Mr. T. E. Gunn; an Egyptian Cobra (*Naia haje*), two Hoary Snakes (*Coronella cana*), from Victoria West, Cape Colony, presented by the Rev. G. H. R. Fisk, C.M.Z.S.; three European Pond Tortoises (*Emys europæa*) European, deposited; a King Snake (*Coluber getulus*) from North America, received in exchange.

OUR ASTRONOMICAL COLUMN.

THE TOTAL SOLAR ECLIPSE OF APRIL 15–16, 1893.—The following particulars of the phenomena of the total solar eclipse of April 15–16, 1893, have been supplied to the Eclipse Committee by Mr. A. M. W. Downing, Superintendent of the *Nautical Almanac* office, for the use of the English observers at the eclipse stations to be occupied in Brazil and Africa:—

Brazil. Longitude 38° 50′ W. Latitude 3° 20′ S.

		d.	h.	m.	s.	Contact from N. point.	Contact from vertical.	Sun's altitude.
Eclipse begins	April	15	22	18	14	136° W.	19° W.	62°
Totality begins		15	23	40	51	Duration 4m. 43·1s.		
Totality ends		15	23	45	34			
Eclipse ends		16	1	11	40	45° E.	84° W.	68°

Local mean times.

Senegambia. Longitude 16° 30′ W. Latitude 14° 15′ N.

		d.	h.	m.	s.	Contact from N. point.	Contact from vertical.	Sun's altitude.
Eclipse begins	April	16	1	5	3	130° W.	156° E.	73°
Totality begins		16	2	27	59	Duration 4m. 12·3s.		
Totality ends		16	2	32	12			
Eclipse ends		16	3	48	1	57° E.	24° W.	35°

Local mean times.

REMARKABLE COMETS.—Bearing this title, Mr. Lynn has written a small book, in which he gives a short survey of the most interesting facts that have occurred in the history of cometary astronomy. As he remarks in the preface, the scope of the work is almost purely historical; but we are sure there are many who will peruse these few pages with great pleasure, for the author has brought together these facts and presented them to the reader in a concise and plain style. We may mention that figures relating to elements of orbits, &c., are at a minimum, Mr. Lynn simply restricting himself to bare accounts. The author concludes by giving a list of the dates at which some of the comets may reappear, from which we make the following extract:—

Date.		Period in years.	
1893	Summer	6½	Finlay's Comet
1894	Winter	3⅓	Encke's ,,
1896	Spring	7½	Faye's ,,
,,	,,	7	Brook's ,,
1897	,,	6½	D'Arrest's ,,
,,	,,	5½	Swift's ,,
1898	Summer	5½	Winnecke's ,,
,,	Autumn	7	Wolf's ,,
1899	Spring	33½	Comet of 1866
,,	Summer	13¾	Tuttle's Comet
,,	,,	7	Holmes's ,,

The comet of 1866, as many of our readers well know, is identical with the meteoric stream through which we pass in November, so we hope that we shall be visited by a fine display.

COMET HOLMES (1892, III.).—Comet Holmes seems to have become somewhat dimmed during the past week, but we nevertheless give the ephemeris for the benefit of those who wish to follow it a little longer.

Ephemeris for 12*h. M.T., Paris.*

RELATIVE POSITIONS OF STARS IN CLUSTER χ PERSEI.—Volume xxx. part iv. of the Transactions of the Royal Irish Society contains the results of the investigations of Sir Robert Ball and Mr. Arthur Rambaut, with respect to the relative positions of 223 stars in the cluster χ Persei as determined photographically. The instrument used throughout was a 15-inch silver on glass reflecting telescope, mounted according to Cook's standard equatorial pattern. For the adjustment of the plate (the size used here being 3¼ × 3¼) and mirror Dr. Johnstone Stoney's collimator was employed, this method ensuring the exact perpendicularity of the photographic plate to the axis of the collimator. The negatives were measured with an instrument made by the same firm, and after the same pattern as that used by Prof. Pritchard, at Oxford, this instrument being supplied with the means of measuring either rectangular or polar coordinates, the former of which has been adopted here throughout. In this memoir the authors treat in detail, by means of figures and formulæ, the equations for orientating the plate for measurement, for computing the differences in Right Ascension and Declination from the centre of the plate, for correcting the relative apparent positions of the stars for effects of separation, observation, nutation, and procession, &c. The measures here given have been obtained from one photograph taken with an exposure of ten minutes, the images under the microscope being susceptible "of very accurate measurement." That only one negative has been employed is due, as the authors say, to pressure of other work and to necessary alterations in the instrument, but they hope to repeat the investigation next autumn. In the table showing the positions, the authors compare their results with those of Vogel and Pihl, and they find that a small difference, depending on the adopted position of the fundamental star, is apparent between the former's declinations, while Pihl's right ascensions differ slightly, though systematically, this discrepancy being due very probably to the different methods of determining the parallels. The memoir concludes with a map showing the relative positions of the stars plotted direct from the x and y coordinates.

L'ASTRONOMIE.—The February number of this journal contains many articles of interest. Prof. Stanislas Meunier gives an account of a meteorite that fell in Algeria; this meteorite has proved to be of iron, containing as much as 91·32 per cent., and a polished surface, when treated with an acid, showed the well-known Widmannstätten figures. M. Flammarion, in addition to an account of "Les Pierres Tombées du Ciel," with reference to "Les Anciens Volcans de la Lune," lately advocated by Prof. Coakley in *Astronomy and Astrophysics*, gives the fourth out of six chapters dealing with the question, "Comment Arrivera la fin du Monde." M. J. Fényi, director of the Observatory of Kalocsa, gives an account of the enormous solar eruption (383,000 kilometres high) that occurred on October 3 last, while a short note on some curious appearances undergone by comet Swift includes six drawings by M. Lorenzo Kropp, taken between March 18 and April 25, and the three photographs taken at the Lick Observatory by Mr. Barnard, all of which indicate the results of tremendous actions, whether they be due to the influences of different forces, "attraction, repulsion, chaleur, électricité, or changements d'état, qui ajissement sur ses astres gazeux dans leur voisinage du soleil." M. Weinck of Prague describes the results of his examination of the Lick negatives with reference to the lunar crater Flammarion, and gives a drawing (which, by the way, can be well seen by half closing the eyes) of its surroundings, together with the three new craters. This number also includes a general summary of the meteorology of the preceding year, the results being given in diagrammatic form, bringing out clearly the diurnal and monthly changes.

JUPITER'S FIFTH SATELLITE.—Mr. Barnard, who has been continuing his observations with respect to the fifth satellite of Jupiter, communicates the results he has obtained to the *Astronomical Journal* (Nos. 285–86). The values of the elongation distances deduced from the measures at elongations are, for eastern elongation, 48″·089 (± 0·061), and for western elongation, 47″·621 ((± 0·176), the probable errors of a single determination being ± 0″·23 and ± 0″·47 respectively. These values are equivalent to the following distances:—

E.	elongation	112,500 ± 143 miles
W.	,,	111,412 ± 412 ,,

The values for the period he gives as

		h. m. s.
September 10–October 21	...	P = 11 57 23·72
September 10–October 28	...	P = 11 57 23·30
September 10–November 20		P = 11 57 22·73

the mean, when proportional weights are applied, being—

11h. 57m. 23·06s.

Among some other figures which Mr. Barnard gives are:—

Hourly motion	30°·111
Velocity in orbit	16·4 miles per second
Equatorial Hor. Par.	21° 51′

Distance from surface of Jupiter 67,000 miles (about).

While working at this satellite he has also been led to measure the equatorial and polar diameters of Jupiter himself, and the following numbers show the values he has deduced, the observations being made through smoked glass:—

Equatorial diameter	89,790 ± 65 miles
Polar ,, ...	84,300 ± 80 miles

GEOGRAPHICAL NOTES.

THE *Times* Berlin correspondent furnishes some interesting notes of Dr. Baumann's recent journeys in the region of the Nile sources, which confirm Mr. Stanley's identification of the Mountains of the Moon. In Urundi the kings were supposed to be lineal descendants of the moon, and the white traveller was hailed as being the returned ghost of a lately-deceased chief. On September 11 the expedition crossed the Akenyaru, which is not, as supposed, a lake, but a river, though the name "Nyanza" is often applied to it. Dr. Baumann also discovered that the so-called Lake Mworengo is in reality a river which flows into the Akenyaru, and came to the conclusion that there was no extensive sheet of water in Ruanda or North Urundi. On September 19 Dr. Baumann arrived at the source of the Kagera (Alexandra Nile), which rises at the foot of the precipitous and wooded hills which form the watershed between the basins of Rufizi and the Kagera. This mountain chain is known to the natives by the name of the "Mountains of the Moon," and is held in peculiar reverence by them. Here Dr. Baumann maintains the real source of the Nile to be, for if "it be acknowledged that the Kagera is the chief feeder of the Victoria Nyanza, it follows that the headwaters of the Nile can be none other than those of the Kagera itself in the Mountains of the Moon in Urundi, within the boundaries of German East Africa."

THE often-discussed scheme of an expedition to the North Pole by way of Franz Josef Land has been revived by Mr. F. G. Jackson, who proposes to lead an expedition next summer, if the means for equipping a ship are forthcoming. Mr. Jackson's plan is to travel with a small party, and establish a chain of depots northward from the most northerly accessible landing-place in Franz Josef Land. He would remain during winter in the most advanced post, and push on each summer with dog-sledges, until the pole is reached. The plan rests on the hypothesis of Franz Josef Land extending to the pole, just as Dr. Nansen's rests on the hypothesis of a transpolar current, but the evidence of the great extension of the land is not very satisfactory. Mr. Jackson's previous Arctic experience is not stated, nor is there any indication given as to whether he intends to travel at his own expense or to appeal for pecuniary help.

THE British South African Company have reserved the Zimbabwe Ruins and the area within a radius of one mile from the top of Zimbabwe Hill for archæological and scientific purposes, and no settlements, farms, or mines will be permitted within that radius.

A BEAUTIFULLY illustrated report on the regulation of Swiss torrents, by the late M. de Salis, has recently been published by the Swiss Government. The natural erosion and surface change which go on at the present day so rapidly among the steep slopes of a mountainous country as to be frequently cataclysmic in their intensity, have to be avoided or endured in inhabited regions. A frequent source of floods is the damming up of a large river by the mud and stones brought down by a freshet in a small tributary. The method of combating this effect is to build a succession of weirs, and cut a parallel canal so that the sediment is caught and the overflow regulated before the escaping water reaches the main valley.

MR. MACKINDER'S fourth Royal Geographical Society's educational lecture, delivered last week, dealt with Central Asian trade- and travel-routes, under the title of "The Gates of India and China."

TWENTY YEARS IN ZAMBESIA.

MR. F. C. SELOUS, the famous hunter and explorer of South Central Africa, gave a summary of his travels to the Royal Geographical Society on Monday evening. His address was illustrated by an exhibition of unusual interest in the tea-room, where a large collection of stuffed specimens of the characteristic African mammalian fauna was arranged. Photographs and various objects illustrative of the rapid development of Mashonaland since the Chartered Company took possession were also shown.

Mr. Selous commenced his African wanderings in 1871, and except for occasional visits to England he has travelled and traded in that continent ever since. In 1872 he and some companions penetrated into Matabeleland to hunt elephants, and had an amusing interview with the chief, Lo-Bengula. Although at that time not an explorer in the scientific sense, the accurate memory of his early wanderings over the country enabled Mr.

Selous to successfully guide the Pioneer Force of the Chartered Company in 1890, when they took possession of Mashonaland.

With regard to the health of Zambesia he says:—"Owing to severe exposure to wet and cold during several days and nights, in the early part of 1872, I got an attack of fever and ague in Griqualand so that I was handicapped before starting for the interior. This fever and ague was exactly what I have seen people get on the high plateau of Mashonaland, during the last few years, from similar exposure to rain and cold. It took me some time to shake off, and was still in my system when I reached Matabeleland, but the attacks only came on when I halted anywhere for a few days. During November and December, 1872, hunting down in the low hot country towards the Zambesi, I was again very much exposed to wet, and on several occasions lay out all night long, without any shelter, drenched through with such heavy rain that it put out the largest fire and converted hard ground into a swamp. I naturally again got soaked with fever poison, but as long as I remained hunting the disease did not show itself. Directly I got back to Bulawayo it broke out, and during a month or so I had several sharp attacks. By that time, however, my sound constitution had choked all the fever germs, and from that day until in 1878, when very severe exposure in Central Africa once more filled me up with malarial poison, I do not remember ever to have had one single hour's illness, or to have taken one drop of medicine. The life I led was, however, if a very hard, at any rate, in many respects, a very healthy one; for the most part I ate nothing but meat and Mashona rice, and drank nothing but tea, usually without milk and sugar—not because I like it so, but because those adjuncts were unobtainable."

North of the Zambesi Mr. Selous made several journeys among the Batongas, and spent a wretched rainy season, almost without equipment, on the Manica table-land. After the rains the country looked charming. The young grass, thanks to the recent heavy rain, had shot up one foot or eighteen inches in height over hill and dale, every tree and shrub was in full leaf, and everything looked green, and fresh, and smiling. Many of the shrubs on the edge of the hills bore sweet-smelling flowers, and, as on all the plateaus of the interior of Africa, small but beautiful ground-flowers were very abundant.

Interesting observations were made on some of the northern rivers. The curious phenomenon of the steady rise of the waters of the Chobe and Machabi—an outlet of the Okavango—was observed from the first week in June until the last week in September, when they commenced to recede. That the Okavango and the Upper Kwando are connected on their upper courses, there can be little doubt, as the waters of the Machabi went on rising suddenly *pari passu* with the Chobe, until the end of September, when both commenced to recede simultaneously.

The explanation of this remarkable phenomenon is difficult, as there are no snow mountains at the sources of the Kwando and Okavango rivers and the Zambesi, which rises in the same latitude, decreases steadily in volume from day to day during the dry season like almost all other rivers in South Central Africa. Besides the channels which still become annually filled with water from the overflow of the Chobe and Okavango river systems, there are many others which are now quite dry, but in which the natives say they once used to travel in canoes.

From 1882 the journeys acquired additional geographical importance, and Mr. Selous proceeded to rectify the maps of Mashonaland laid down by earlier travellers, taking constant compass bearings, sketching the course of rivers, and fixing the position of the junction of tributaries. The value of this work was made manifest in a magnificent large scale map of the country, drawn as well as surveyed by Mr. Selous, which was used to illustrate the lecture. It would be impossible, without practically reproducing the whole address, to do justice to the immense variety and solid value of the contributions to African geography made by this most energetic of pioneers; or to the thrilling adventures, the recital of which was listened to with breathless attention and greeted with the heartiest applause. With the exception of a treacherous night attack made upon his camp by the Mashuku-sumbwe, led by a few rebel Marotse, in 1888, he had never had any other serious trouble with the natives. During his twenty years' wanderings he went amongst many tribes who had never previously seen a white man, and he was always absolutely in their power, as he seldom had more than from five to ten native servants, none of whom were ever armed.

THE DISTRIBUTION OF POWER BY ELECTRICITY FROM A CENTRAL GENERATING STATION.

ON Friday evening, the 3rd inst., Mr. A. Siemens delivered at the Royal Institution an interesting lecture on the ways in which science is applied to practice. In the course of the lecture he made the following remarks on the distribution of power by electricity from a central generating station:—

Before entering further into this, let me remind you that the earliest magneto-electric machines were used nearly sixty years ago for the production of power. I will mention only Jacobi's electric launch of 1835 as an example. It must, therefore, be considered altogether erroneous to ascribe the invention of the transmission of power to an accident at the Vienna Exhibition in 1873, when, it is said, an attendant placed some stray wires into the terminals of a dynamo machine; it began to turn, and the transmission of power was first demonstrated. As a matter of fact, Sir Wm. Siemens once informed me, that his brother Werner was led to the discovery of the dynamo-electric principle by the consideration that an electro-magnetic machine behaved like a magneto-electric machine, when a current of electricity was sent into it, viz. both turn round and give out power. It was, of course, well known that a magneto-electric machine produces a current of electricity, when turned by mechanical power, and Werner concluded that an electro-magnetic machine would behave in the same manner. We all know that he was right, but I relate this circumstance only as a further proof that the generation of power by electric currents has been a well-known fact long previous to the Vienna Exhibition.

Another well-known instance of transmission of power to a distance is furnished by the magneto-electric ABC telegraph instruments, where the motion at the sending end supplies the currents necessary to move the indicator at the receiving station.

As an illustration of the distribution of power by electricity, I will briefly describe some radical alterations that have been made at the works of Messrs. Siemens Brothers and Co., by the introduction of electric motors in the place of steam engines.

[A diagram on the wall showed in outline the various buildings in which work of different kinds is carried on with the help of different machines.]

Electric motors are supplying the power, sometimes by driving shafting to which a group of tools is connected by belting, and sometimes by being coupled direct to the moving mechanism. Each section of the works has its own meter, measuring the energy that is used there, and all of them are connected by underground cables to a central station, where three sets of engines and dynamos generate the electric current for all purposes. There are two Willans and one Belliss steam engines, each of 300 horse-power, coupled direct to the dynamos, and running at a speed of 350 revolutions per minute. Room is left for a fourth set, but including some auxiliary pumps and the switchboards for controlling the dynamos and for distributing the current, the whole space occupied by 1200 horse-power measures only 32 × 42 feet. Close by are the condensers and three high-pressure boilers, which have replaced some low-pressure ones formerly used for some steam engines driving the machinery in the nearest building.

The advantages that have been secured by the introduction of electric motors may be briefly stated under the following heads:—

1. Various valuable spaces formerly occupied by steam engines and boilers have been made available for the extension of workshops, and these are indicated on the diagram by shading.

2. By abolishing to a great extent the mechanical transmission of power a considerable saving is effected in motive power, which is especially noticeable at times when part only of the machinery is in use.

3. As the electric motors take only as much current as is actually required for the work they are doing, a further saving is effected, and at the same time the facility with which the speed of the motors can be altered without their interfering with each other presents a feature that is absent from mechanical transmission.

4. The big steam engines being compound and condensing, produce a horse-power with a smaller consumption of fuel than the small high-pressure steam engines scattered throughout the works.

5. The numerous attendants of the old steam engines and boilers have mostly been transferred to other work, only a few of them are required at the central station, and one or two men can easily look after all the electric motors used in the various parts of the works.

Elsewhere equally favourable results have been obtained by the introduction of electrical distribution of power, and in this respect I beg to refer you to a paper read before the German Institution of Civil Engineers by Mr. E. Hartmann in April of last year, and to a paper read by Mr. Castermans before the Society of Engineers in Liège, in August last, in which he compares in detail various methods of transmission of power, of which the electrical one was adopted for a new small arms factory.

We may therefore take it for granted that the advantages alluded to above have not resulted from local circumstances at Woolwich, but that they can be realised anywhere by the adoption of the electric current for distributing power from a central station.

At first sight this result appears to be of interest only to the manufacturer; but the development of this idea may lead to far-reaching consequences, when we consider that cheap power is one of the most important requisites for cheap production.

While power was generated by steam engines the cost of producing one-horse-power varied a good deal in the different parts, and the various owners could not have obtained their power on equal terms, those possessing the largest steam engines having a distinct advantage. This inequality is done away with altogether when the power is distributed by electricity, as the current can be supplied for large or small powers at the same rate per Board of Trade unit. It is therefore clear that the establishment of central stations for the generation of electricity on a large scale will bring about the possibility of small works competing with large works in quite a number of trades where cheap power is the first consideration.

Another circumstance favouring small works is the diminution of capital outlay brought about by the employment of electric motors. Not only are the motors cheaper than boilers and steam engines of corresponding power would be, but the outlay for belting and shafts is saved, and the structure of the building need not be as substantial as is necessary where belts and shafting have to be supported by it. A commencement has already been made in this direction by the starting of electric light stations, where the owners do all in their power to encourage the use of the current in motors, in order to keep the machinery at their central station more uniformly at work. The introduction of electricity as motive power will apparently present a strong contrast to the effect steam has had on the development of industries for the reasons already stated; and in addition there are many cases where the erection of boilers and steam engines, or even of gas engines, would be inadmissible on account of want of space or of the nuisances that are inseparable from them. Motive power will therefore be available in a number of instances where up to the present time no mechanical power could be used, but the work had to be done by manual labour or not at all.

You may have noticed that I have confined my remarks hitherto to the case of distributing electricity over a limited area, but that I have not yet discussed the question of transmitting power to a great distance.

Theoretically we have been told over and over again that the motive power of the future will be supplied by waterfalls, and that their power can be made available over large areas by means of electric currents. As a prominent example the installation is constantly mentioned by which the power of a turbine at Lauffen was transmitted over a distance of 110 statute miles to the Frankfurt Exhibition with an efficiency of 75 per cent. No doubt this result is very gratifying from a purely scientific point of view, but unfortunately in practical life only commercially successful applications of science will have a lasting influence, and in this respect the Lauffen installation left much to be desired. On the one hand science tells us that the section of the conductor can be diminished as the pressure of electricity is increased, and it appears to be only necessary to construct apparatus for generating electricity at a sufficiently high pressure so as to reduce the cost of a long conductor to reasonable limits. On the other hand, experience shows that at these high potentials the insulation of the electric current becomes a most difficult problem, and for practical purposes difficulty means an increased outlay of money.

MAGNETICAL AND METEOROLOGICAL OBSERVATIONS MADE AT THE GOVERNMENT OBSERVATORY, BOMBAY, 1890, WITH AN APPENDIX.

THIS volume, we are informed, is the thirtieth of the series of "Bombay Magnetical and Meteorological Observations," extending the previous record from 1845 to 1889, up to 1890. At this well-organized observatory, under the direction of Mr. Charles Chambers, continuous registration of the different magnetical and meteorological elements is maintained by means of automatic recording instruments, of which there are five sets, the magnetographs (three), the barograph, the thermograph, the pluviograph, and the anemograph, all being photographic records excepting that of the anemograph, which is mechanical. In addition eye observations are also made, including the usual meteorological observations of weather and other phenomena. Daily values for 1890 are given of atmospheric pressure, temperature of the air, rainfall, wind and cloud, with some further discussion of the anemometric results; five day means of meteorological elements are also given. In the magnetic section is found observations of absolute horizontal force, magnetic declination and dip, at short intervals throughout the year. And in the appendix is contained a collection of the monthly values of declination and horizontal force from 1868 to 1890, accompanied by a discussion of the secular changes of these elements. In regard to declination the results show the eastern magnetic declination to have increased during the early years of the series, arriving at a maximum at about the middle of the period, and decreasing in the later years. Taking the annual values of declination to be represented by the formula $\delta = at^2 + bt + c$, it is found that the maximum easterly declination occurred in 1880, with value 0° 57′ 17″. This actual observation of the turning-point at this place, in the long cycle of change, is very interesting. The horizontal force values are similarly discussed, but in this case the values are generally progressive. There is no discussion of diurnal inequalities, but these were elaborately treated in a previous volume. Magnetic observatories in tropical and southern regions are valuable. Many exist in Europe with others scattered over different parts of the northern hemisphere, generally publishing with regularity their results, but there is a want of similar establishments in southern regions. There are magnetic observatories at Batavia, Mauritius, and Melbourne, but we do not get from them all that might be desired. England possesses no regularly maintained southern establishment of this kind. A magnetic observatory existed many years ago at the Cape of Good Hope, which, long since destroyed, we believe, by fire, was never again reorganized, which was unfortunate. The attention of the Magnetic Committee of the British Association was several years ago drawn to the question of re-establishing the Cape Magnetic Observatory, and in the Report of the Committee for the year 1891 it is stated that a representation had been made to the Admiralty as to the desirability of so doing. An efficient magnetic observatory in such a position, with regular publication of the results, would provide information of great value for the discussion of various questions in magnetic phenomena that now arise. It would be well also if the study of earth currents were taken up at some of the magnetic observatories in different parts of the world by continuous photographic registration thereof, for the better elucidation of the physical relation that may exist between magnetic and earth current variations, in regard to which our knowledge seems at present to be so imperfect.

BACTERIA AND BEER.

THE examination of water for micro-organisms since the publication by Koch in 1881 of his beautiful process of gelatine-plate cultures has come more and more into general use, as the public has gradually become cognisant of its value for hygienic and practical purposes. But whilst affording much valuable information on many subjects, Hansen has pointed out, as far back as 1888, that as applied to the examination of waters for brewing purposes it cannot be considered wholly satisfactory. Working on lines suggested by Hansen, Holm has recently published a paper, "Analyses biologiques et zymotechniques de l'eau destinée aux brasseries" (*Compte-rendu des travaux du laboratoire de Carlsberg*, vol. iii., Copenhagen, 1892), in which he describes a large number of investigations on brewing-waters examined by Hansen's method, and in which the relative merit for brewing purposes of Koch's and Hansen's processes is also discussed. It is obvious that the organisms to be feared in a brewery are those which will flourish in wort or beer, and that the mere knowledge of the number of bacteria in any given water as revealed by gelatine plate cultures is but of little use. Hence Hansen and his pupils reject for such examinations gelatine-peptone, substituting sterilised wort and beer as a culture material. An interesting table is given showing the different bacteriological results obtained in the use of gelatine-peptone, gelatine to which wort had been added, wort alone, and beer. For example, whereas a particular brewing-water yielded by gelatine-peptone about 8000 colonies per c.c., the majority of which were bacteria; gelatine mixed with wort gave about 14, all being moulds; in wort 5·4 were found, consisting of bacteria and moulds, whilst sterilised beer gave only 0·8 for the c.c., and only moulds. Holm points out that to estimate the value of a water for brewing purposes a note should also be made of the rate at which the organisms develop in the wort or beer, for should signs of growth only declare themselves after four or five days in the laboratory under favourable conditions of temperature and in the absence of competing forms, it is not unnatural to expect that their vitality, under the more rigorous conditions imposed during brewing operations, would be so far impaired that their development, if taking place at all, would only be accomplished with great difficulty. Although instances occurred in which even after the lapse of seven days growths first made their appearance, yet in the majority of cases the incubation of the wort-flasks for one week was sufficient. Holm is of opinion that the use of other culture materials besides wort is unnecessary, as all the organisms which successfully develop in beer can also grow in wort. Moreover, it was found that in the process of sterilisation to which the beer was submitted a considerable proportion of its alcohol was lost, thus diminishing its natural bactericidal properties. A beer containing 5 to 6 per cent. of alcohol, after sterilisation, had this reduced to 2·8 per cent., although it even then proved a very unfavourable medium for the development of ordinary water bacteria. As a practical outcome of his experiments Holm emphasises the necessity of a careful selection of the site for the erection of the water-reservoir attached to a brewery. The reservoirs of the old brewery at Carlsberg are placed in the immediate vicinity of the storehouses for grain and malt, consequently in this water a far larger number of moulds were met with than in the water examined from differently situated reservoirs supplying the laboratory and another brewery. But although moulds usually predominate, yet they are not so much to be feared as the bacteria, more especially those which are found in the fermentation chamber, for although they are unable to assert themselves to any considerable extent in the beer preserved in the store cellar, yet when it is drawn off and thus aërated, and the temperature raised by its transference to bottles or small casks, these organisms can develop with an astonishing rapidity, and produce great mischief.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Dr. Shore, of St. John's College, late Examiner in Physiology, has been elected a member of the Special Board for Medicine; Dr. A. Macalister, F.R.S., St. John's, has been appointed an elector to the Professorship of Chemistry; Dr. Ferrers, F.R.S., Master of Gonville and Caius, an elector to the Plumian Professorship of Astronomy; Prof. Newton, F.R.S., Magdalene, an elector to the Professorship of Anatomy; Dr. Phear, Master of Emmanuel, an elector to the Professorship of Botany; Dr. R. D. Roberts, Clare, an elector to the Woodwardian Professorship of Geology; Mr. P. T. Main, St. John's, an elector to the Jacksonian Professorship of Chemistry, &c.; Mr. R. T. Glazebrook, F.R.S., Trinity, an elector to the Professorship of Mineralogy; Mr. F. Darwin, F.R.S., Reader in Botany, an elector to the Professorship of Zoology and Comparative Anatomy; Mr. W. D. Niven, F.R.S., Trinity, an elector to the Cavendish Professorship of Physics; Dr. Phear, an elector to the Professorship of Mechanism; Prof. Liveing, F.R.S., St. John's, an elector to the Downing Professorship of Medicine; Dr. P. H. Pye-Smith, F.R.S., an elector to the Professorship of Physiology; and Sir G. M. Humphry, F.R.S., an elector to the Professorship of Pathology.

SCIENTIFIC SERIALS.

American Journal of Science, February.—Isothermals, isopiestics, and isometrics relative to viscosity, by C. Barus. The substance experimented upon was marine glue, and its viscosity at different pressures and temperatures was measured by a transpiration method, the substance being forced through steel tubes 10 cm. long and 0·5 to 1 cm. in diameter under pressures as high as 2000 atmospheres. It was found that in proportion as the viscosity of a body increases with fall of temperature, its isothermal rate of increase with pressure also increases. Speaking approximately, the rate at which viscosity increases with pressure at any temperature is proportional to the initial viscosity at that temperature, and, conversely, the rate of decrease with temperature is proportional to the actual temperature and independent of the pressure. An interesting result is that in high pressure phenomena at least 200 atmospheres must be allowed per degree Centigrade, in order that there may be no change of viscosity.—"Potential," a Bernoullian term, by Geo. F. Becker.—Datolite from Loughboro, Ontario, by L. V. Pirsson.—A new machine for cutting and grinding thin sections of rocks and minerals, by G. H. Williams.—Stannite and some of the alteration products from the Black Hills, S.D., by W. P. Headden.—Occurrence of hematite and martite iron ores in Mexico, by R. T. Hill, with notes on the associated igneous rocks, by W. Cross.—Cæsium lead and potassium-lead halides, by N. L. Wells.—Ceratops beds of Converse County, Wyoming, by J. B. Hatcher.—Use of planes and knife-edges in pendulums for gravity measurements, by T. C. Mendenhall. The employment of a pendulum to which the plane is attached instead of the knife-edge presents several advantages. The plane may be accurately adjusted at right angles to the rod by simple optical methods. A pendulum carrying a plane instead of a knife-edge is vastly less liable to injury, and the knife-edge being no longer an integral part of the vibrating mass can be reground or replaced at will. The length of the pendulum is more capable of accurate determination, since the error introduced by the yielding of the edge under pressure is eliminated. The disadvantage due to the uncertain position of the axis of oscillation can be mechanically got rid of by a proper construction of the raising and lowering apparatus, and experiment shows that the period in the course of twelve sets of swings of an hour each does not vary by as much as one part in a million. The best angle for the knife-edge was found to be about 130°, the material used being agate.—Preliminary note on the colours of cloudy condensation, by C. Barus. If saturated steam is allowed to pass suddenly from a higher to a lower temperature in uniformly temperatured, uniformly dusty air, a succession of colours is seen by transmitted white light which, taken in inverse order, are absolutely identical with the colours of Newton's rings of the first two orders.—Lines of structure in the Winnebago Co. meteorites and in other meteorites, by H. A. Newton (reprinted in this issue).—Preliminary note of a new meteorite from Japan, by Henry A. Ward.—Restoration of Anchisaurus, by O. C. Marsh (see Note, p. 349).

American Journal of Mathematics, vol. xiv. No. 4 (Baltimore, 1892).—The main object of the note on the use of supplementary curves in isogonal transformation, by R. A. Harris (pp. 291–300), is to show how the problem of representing one plane conformably upon another, using any real function of the variable, may be made to depend upon the problem of constructing supplementary curves from given tracings of the corresponding principal curves. It is well illustrated by four carefully drawn figures. In her memoir (pp. 301–325) on the higher singularities of plane curves, Miss C. A. Scott goes over ground to some extent previously occupied by Profs. Cayley and H. J. S. Smith in writing on the same subject (*cf.* also papers by Brill and Nöther in the *Math. Annalen*, vols. ix. xvi. xxiii.). Nöther's results are presented in analytical form, "involving no dependence on geometrical ideas even when geometrical terms are used." The author brings out his results more clearly by making use of Dr. Hirst's method of quadric inversion. The text is accompanied by twenty-seven drawings of curves. Mr. W. H. Metzler, writing on the roots of matrices (pp. 326–377), employs a modification of Dr. Forsyth's method of proving Cayley's "identical equation" ("Messr. of Mathematics," vol. xiii.) to prove Sylvester's law of latency and Sylvester's theorems. He also investigates the existence of roots of matrices for different indices, and in particular the roots of nilpotent matrices. A careful analysis of the contents is prefixed to the memoir. Dr. F. N. Cole (pp. 378–388) discusses the simple groups from order 201 to order 500, and arrives at the conclusion that "the possible orders of simple groups of compound order between 201 and 500 are reduced to 360 and 432." The volume closes with a note (p. 389) by M. M. D'Ocagne, correcting a slight mistake in a memoir by him in the 1888 volume, entitled "Sur certaines courbes," and the title page and index.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, February 2.—"On a Meteoric Stone found at Makariwa, near Invercargill, New Zealand." By G. H. F. Ulrich, Professor of Mining and Mineralogy in the University of Dunedin, N.Z. Communicated by Prof. J. W. Judd, F.R.S.

The specimen described in this memoir was found in the year 1879 in a bed of clay, which was cut through in making a railway at Invercargill, near the southern end of the Middle Island of New Zealand. Originally, this meteorite appears to have been about the size of a man's fist, and to have weighed four or five pounds, but it was broken up, and only a few small fragments have been preserved. The stone evidently consisted originally of an intimate admixture of metallic matter (nickel-iron) and of stony material, but much of the metallic portion has undergone oxidation. Microscopic examination of thin sections shows that the stony portion, which is beautifully chondritic in structure, contains olivine, enstatite, a glass, and probably also magnetite; and through these stony materials the nickel-iron and troilite are distributed. The specific gravity of portions of the stone was found to vary between 3·31 and 3·54, owing to the unequal distribution of the metallic particles. A partial chemical examination of this meteorite was made by the author and Mr. James Allen, but the complete analysis has been undertaken by Mr. L. Fletcher, F.R.S., of the British Museum. The analysis, which when finished will be communicated to this Society, has gone so far as to show that the percentage mineral composition of the Makariwa meteorite may be expressed approximately by the following numbers: nickel-iron 1, oxides of nickel and iron 10, troilite 6, enstatite 39, olivine 44.

Physical Society, January 27.—Walter Baily, Vice-President, in the chair.—Prof. S. P. Thompson, F.R.S., made a communication on Japanese magic mirrors, and exhibited numerous specimens showing the magic properties. Referring to the theory of the subject, he said the one now generally accepted was that proved by Profs. Ayrton and Perry in 1878, who showed that the patterns seen on the screen were due to differences in curvature of the surface. The experiments he now brought forward fully confirmed their views. Brewster had maintained that the effects were due to differences of texture in the surfaces causing differences in absorption or polarisation, but the fact that the character of the reflected image depended on the convergency or divergency of the light, and on the position of the screen, showed this view to be untenable. Another proof of the differing curvature theory was then given by covering a Japanese mirror with a card having a small hole in it. On moving the card about, the disc of light reflected from the exposed portion varied in size, showing that the curvatures of portions of the surfaces were not the same. The same fact was proved by a small spherometer, and also by reflecting the light passing through a coarse grating from the mirror, the lines being shown distorted. To put the matter to a test demanded by Brewster, he had a cast taken from a mirror by his assistant, Mr. Rousseau; this had been metallised, silvered, and polished, and now gave unmistakable evidence of the pattern reflected from the original. The true explanation of how the inequalities of curvature were brought about during manufacture had also been given by Profs. Ayrton and Perry, but there were some questions of detail on which difference of opinion might exist. The late Prof. Govi had noticed that warming a mirror altered its possibilities. A thick mirror which gave no pattern whilst cold developed one on being heated, was shown to the meeting. Prof. Thompson also showed that a glass mirror having a pattern cut on the back developed magic properties when the mirror was bent. When made convex the reflected pattern was dark on a light ground, and when made concave, light on a dark ground. Warming ordinary mirror-glass by a heater whose surface was cut to a pattern gave similar effects. Very thick glasses could be affected in this way. On passing a spirit lamp behind a strip of mirror, a dark band could be caused to pass along the screen illuminated by light reflected from the mirror. By writing on lead foil and pressing the foil against a glass mirror by a heater, the writing was caused to appear on the screen. Prof. Thompson had also found that Japanese mirrors which are not "magic" when imported, could be made so by bending them mechanically so as to make them more convex. In conclusion, he showed a large mirror 15″ × 11″, the reflection from which showed the prominent parts of the pattern on its back with the exception of two conspicuous knobs; these knobs gave no indication of their existence. Prof. Ayrton said the simple mechanical production of the magic property described by Prof. Thompson led him to think that some experiments on "seeing by electricity" by the aid of selenium cells which Prof. Perry and himself made some years ago, might lead to some result if repeated with thinner reflectors. Speaking of the effect of scratching the back of a Japanese mirror, he pointed out that if metal be removed by pressure a bright image was seen, whilst if removed chemically a dark image resulted. Since the original paper on the subject was written he had been led to modify his views as to the effect of amalgamation, for some time ago he showed the society how brass bars were bent if one edge be amalgamated, thus proving that enormous forces were developed. He now regarded amalgamation as an important part of the manufacture. Mr. Trotter inquired if it had been proved that there was no difference in the metal in the thick and thin parts? One would expect the thin parts to be harder and polished away less. After some remarks by Mr. J. W. Kearton and Major Rawson, Prof. Thompson said the magic effects produced by heating the back of a glass mirror remained for a short time after the heater was removed. The question of whether differences in hardness of the thick and thin parts of a mirror were of consequence in the production of the magic property had been tested by using sheets of brass thickened by pieces soldered to the back as mirrors, and found to be unimportant. Prof. Ayrton also described an experiment pointing to the same conclusion.—Mr. W. F. Stanley read a paper on the functions of the retina—(i.) The Perception of Colour. Referring to Young's three-nerve theory of colour-sensation, the author said Prof. Rutherford had pointed out that there was no necessity to assume that different nerves conveyed different colour-sensations, for as a telephone wire would transmit almost an infinite variety of sound vibrations, so the nerves of the retina were probably equally capable of conveying all kinds of light vibrations. Prof. Rutherford had further pointed out that the image of a star could not possibly cover three nerve-terminals at once, and therefore could not be seen as white if Young's theory was correct. The author then described Helmholtz's experiments with a small hole in a screen illuminated by spectrum colours. For red illumination the greatest distance at which the hole could be seen sharply defined was 8 feet, and for violet 1½ feet. When the hole was covered with purple glass, or with red and violet glasses superposed, and a bright light placed behind, the eye, when accommodated for red light, saw a red spot with a violet halo round it, and when focussed for violet light, saw a violet spot with circle of red. These experiments the author thinks show that the chromatic sense in distinct vision under critical conditions (*i.e.* where a single nerve or a small group of nerves is concerned) depends on the colours being brought to foci at different distances behind the crystalline lens. He also infers that the same focal position in the eye cannot convey simultaneously the compound impression of widely separated colours. Helmholtz's observations are further examined in the paper, and a series of zoetrope and colour disc experiments described which tend to show that the eye cannot follow rapid changes of colour. Changes from red to violet could be followed much more quickly than from violet to red. The red impressions were, however, more permanent. The observed effects were found to depend on the intensity of the light, and also on the distance of the eye from the coloured surface. Summing up his observations, the author infers that by systems of accommodation of the eye, the colours of the spectrum are brought to focus on special parts or points of the rods or cones of the retina, such focal points being equivalent, by equal depths or distances from the crystalline lens, to a focal plane formed across the whole series of nerve-terminals. That all the rays of light from an object, or part of an object, of very small area and of any spectrum colour, will converge to a point upon a nerve terminal, and that this terminal will be most excited by the light. At the end of the paper Dr. Stanley Hall's views of nerve structure are examined. Captain Abney thought the results of the zoetrope experiments were what one would have expected when pigmentary colours were used. To be conclusive, such experiments must be conducted with pure spectrum colours. The statement about the size of star images being less than that of a nerve terminal would probably need revision. Speaking of colour vision, he said the modern view was to regard light as producing chemical action in the retina, which action gave rise to the sensation of colour. On the author's theory he could not see how colour-blindness could be explained. Mr. Trotter said he understood Helmholtz to have proved that nerves could distinguish quantity, but not the quality of a stimulus. Since the speed at which stimuli travelled to the brain was about 30 metres a second, the wave length of a light vibration, if transmitted in this way, would be very small. Taking Lord Kelvin's estimate of the minimum size of molecules of matter, it followed that there must be many wave lengths in the length of a single molecule. This, he thought, hardly seemed possible. Mr. Lovibond pointed out that the observations referred to by the author could be equally well explained on the supposition that six colour sensations existed. The confusion of colours he had mentioned arose from lack of light. Mr. Stanley replied to some of the points raised by Captain Abney. In proposing a vote of thanks to Mr. Stanley, the chairman said it had been shown that light could be resolved into three sensations, but it was not known how this resolution occurred. Prof. S. P. Thompson said the gist of Mr. Stanley's paper seemed to be that lights of different colours were concentrated at points situated at different depths in the retina, the violet falling on the part nearest the crystalline lens, and the red furthest away. Another view of the action was that the different sensations might be due to the vibrations of longer wave length having to travel greater distances along the nerve terminals before they were completely absorbed.

Mathematical Society, January 12.—Mr. A. B. Kempe, F.R.S., President, in the chair.—The President (Prof. Elliott, F.R.S., Vice-President, in the chair) read a paper on the application of Clifford's graphs to ordinary binary quantics (second part). In the first part it was pointed out that by some small modifications and a recognition of the fact that the covariants of $f(x, y)$ are invariants of the two quantics $f(X, Y)$ and $(Xy - Yx)$, the theory of graphs, which had been left in an unfinished state by the late Prof. Clifford, furnished a complete method of graphically representing the invariants (and therefore the covariants) of binary quantics. The method as modified depends essentially on the fact that any invariant, when multiplied by a suitable number of polar elements U, U′, V, V′, &c., can be expressed as a "pure compound form" (or sum of two or more such forms), the product of a number of "simple forms." Each of the latter has a "mark," viz. one of the letters *a*, *b*, *c*,...... and has also a certain valence, 0, 1, 2, 3, &c. and these being given it is fully defined, *e.g.*, the simple form of mark *a* and valence 3 is graphically

having three radiating bonds, and is algebraically

$$a_0\,\mathrm{UVW}+a_1\,(\mathrm{U'VW}+\mathrm{UV'W}+\mathrm{UVW'})+a_2\,(\mathrm{UV'W'}\\+\mathrm{U'VW'}+\mathrm{U'V'W})+a_3\,\mathrm{U'V'W'},$$

the pairs of polar elements U, U′; V, V′; and W, W′, corresponding to the three bonds of the graphical representation. A pure compound form is graphically represented by a number of simple forms having their bonds connected so that there are no free ends. If in the algebraical expression of a compound form two simple forms both contain the pair of polar elements U, U′, there will be a bond connecting their graphical representations; if the two simple forms both contain two pairs of such elements, viz. U, U′ and V, V′, there will be two bonds connecting their graphical representations and so on; if they contain no common pair their graphical representations will have bond connecting them. A pair of polar elements will appear in two simple forms only, so that each bond in the graphical representation of a compound form corresponds to a distinct pair of polar elements. If the algebraical expression corresponding to a graph be multiplied out, it will be found to consist of two distinct factors, viz.:—(1) the product of all the polar elements, and (2) a function of the letters a_0, a_1, a_2...... ; b_0, b_1, b_2,...... ; &c., &c.; corresponding to the marks *a*, *b*, ...&c. of the simple forms contained in the compound form represented by the graph, the latter factor being an invariant of the quantics

$$(a_0,\ a_1,\ a_2,\ldots\ldots\ldots a_\alpha)(x,\ y)^\alpha$$
$$(b_0,\ b_1,\ b_2,\ldots\ldots\ldots b_\beta)(x,\ y)^\beta$$
&c., &c.

where α is the valence of the simple forms of mark *a*, which are here supposed to be all of the same valence, and similarly in the case of β, γ, &c.

In this second part a method of algebraically representing invariants is considered, which is directly derivable from the method of the first part, and was suggested by the graphs; but differs essentially from the earlier method in that it is independent of the use of polar elements. It shows, moreover, that the graphs may be regarded as absolutely equivalent to the invariants they represent, in lieu of being equivalent to those invariants multiplied by a number of polar elements. This second method deals in the first instance with "primary" invariants, *i.e.* invariants of two or more quantics linear in the coefficients of each. If these quantics are

$$(a_0,\ a_1,\ a_2,\ldots\ldots\ldots a_\alpha)(x,\ y)^\alpha$$
$$(b_0,\ b_1,\ b_2,\ldots\ldots\ldots b_\beta)(x,\ y)^\beta$$
&c., &c.,

and we take

$$\boldsymbol{a}=a_1\frac{d}{da_0}+a_2\frac{d}{da_1}+a_3\frac{d}{da_2}+\text{\&c. } \textit{ad infinitum.}$$
$$b=b_1\frac{d}{db_0}+b_2\frac{d}{db_1}+b_3\frac{d}{db_2}+\text{\&c. } \textit{ad infinitum.}$$
&c., &c.

we may express any primary invariant by an expression, or the sum of two or more expressions, consisting of the product of differences of the operators *a*, *b*,..... operating upon the product of the corresponding leading terms, a_0, b_0, &c. Thus

$$(a-b)^2a_0b_0 \equiv a_2b_0-2a_1b_1+a_0b_2$$

is an invariant of the two quantics

$$a_0x^2+2a_1xy+a_2y^2,$$
$$b_0x^2+2b_1xy+b_2y^2,$$

linear in the coefficients of each; and

$$(a-b)^2(a-c)a_0b_0c_0 \equiv a_3b_0c_0-a_2b_0c_1-2a_2b_1c_0+2a_1b_1c_1+\\a_1b_2c_0-a_0b_2c_1$$

is a similar invariant of the three quantics

$$a_0x^3+3a_1x^2y+3a_2xy^2+a_3y_1^3$$
$$b_0x^2+2b_1xy+b_2y^2$$
$$c_0x+c_1y.$$

These two invariants are graphically represented by

and

respectively, where the relation between the algebraical and graphical expressions is obvious, viz. to every letter *p* in the algebraical representation there corresponds a nucleus including the mark *p*, and to every factor $(p-q)$ in the algebraical representation there corresponds a bond connecting the nuclei of marks *p* and *q*.

We can pass to invariants of higher degrees in the coefficients of the various quantics by substituting like coefficients for unlike. Thus, if we make $b_0=a_0$, $b_1=a_1$, $b_2=a_2$, the primary invariant

$$a_2b_0-2a_1b_1+a_0b_2$$

becomes the invariant of degree 2

$$2(a_0a_2-a_1^2)$$

of the single quantic

$$a_0x^2+\ 2a_1xy\ +\ a_2y^2.$$

This invariant will be graphically represented by substituting the mark *a* for the mark *b* in the graph representing the corresponding primary invariant.

If we proceed to deal in the same way with the invariant,

$$a_3b_0c_0\ -\ a_2b_0c_1\ -\ 2a_2b_1c_0\ +\ 2a_1b_1c_1\ +\ a_1b_2c_0\ -\ a_0b_2c_1,$$

we get, as the invariant represented by substituting for the marks *b* and *c* the mark *a*, the expression of the third degree,

$$a_3a_0^2\ -\ 3a_2a_1a_0\ +\ 2a_1^3.$$

This is not an invariant of a single quantic, but of the three

$$a_0x^3 + 3a_1x^2y + 3a_2xy^2 + a_3y^3$$
$$a_0x^2 + 2a_1xy + a_2y^2$$
$$a_0x + a_1y.$$

It bears, however, a definite relation to the first of these three quantics, viz. : it is a *seminvariant* of that quantic, being in fact the source of its cubic-covariant J. The paper points out that all seminvariants are thus invariants of two or more quantics, and can therefore be represented by graphs; the difference between a graph representing an invariant of a quantic and one representing a seminvariant of the same quantic consisting merely in this, that the simple forms, *i.e.* the small circles or nuclei of the graphs in the former case are all of the same "valence," *i.e.* have the same number of bonds, while in the latter, though of like marks, they differ in valence. The classification of seminvariants, according to the valences of the simple forms composing them, or, in other words, according to the orders of the quantics of the systems of which they are respectively invariants, obviously throws considerable light upon their structure.

The paper also deals with the breaking up of graphs into simpler ones; and gives a theorem upon the subject which leads to some interesting results. It points out, moreover, how the graphs representing the sources of covariants can be instantaneously derived from those representing the covariants themselves.

On the evaluation of a certain surface-integral and its application to the expansion of the potential of ellipsoids in series, Dr. Hobson.

On the vibrations of an elastic circular ring, by Mr. A. E. H. Love.—The ring is supposed to be of small circular section of radius c, and the elastic central-line a circle of radius a. There are four ways of displacing the ring. A point on the central-line may move along the radius of the circle which is its primitive form, or perpendicular to the plane of this circle, or along the tangent to this circle; and the circular sections may be displaced by rotation about the central-line. The modes of vibration fall into four classes, of which two are physically important :—Class I. Flexural vibrations in plane of ring.—These were investigated by Hoppe in 1871 (*Crelle*, bd. lxxiii.). The motion of a point on the elastic central-line is compounded of a displacement in and out along the radius and a displacement along the tangent to the circle, so proportioned that the central-line remains unstretched, and the nodes of the former displacement are the antinodes of the latter. There must be at least two wave-lengths to the circumference, and the frequency ($p/2\pi$) of the mode in which there are n wave-lengths to the circumference is given by the equation

$$p^2 = \frac{1}{4}\,\frac{n^2(n^2-1)^2}{n^2+1}\,\frac{E}{\rho_0}\,\frac{c^2}{a^4}$$

in which E is the Young's modulus, and ρ_0 the density of the material. Except for the numerical coefficient this is precisely similar to the formula for the lateral vibrations of a straight bar of the same material and section and of length πa (for which the fundamental tone has the same wave-lengths). The sequence of component tones when n is very great is ultimately identical with that of the tones of a free-free bar of length πa, but the sequence for the low tones is quite different to that for a bar. Class II. Flexural vibrations perpendicular to the plane of the ring.—It is found to be impossible to make the ring vibrate freely so that each particle of the elastic central-line moves perpendicular to the plane of the ring, unless at the same time the sections turn about the central-line through a certain angle. The flexure perpendicular to the plane of the ring is always accompanied by *torsion*. As in Class I. there must be at least two wave-lengths to the circumference, and the frequency of the mode in which there are n wave-lengths to the circumference is given by the equation

$$p^2 = \frac{1}{4}\,\frac{n^2(n^2-1)^2}{1+\sigma+n^2}\,\frac{E}{\rho_0}\,\frac{c^2}{a^4}$$

where σ is the *Poisson's ratio* for the material and the other constants have the same meaning as before. (For most hard solids σ is about $\frac{1}{4}$.) Since n must be at least 2 the sequence of tones is very nearly the same as in the vibrations of Class I., but the pitch is slightly lower, the ratio of the frequencies for the gravest tones being $\sqrt{\frac{21}{20}}$, which is very little less than a *comma*. For the higher tones, as we should expect, there is no sensible difference. These two classes include all that have much physical importance. The remaining types can be classified as :—Class III. Extensional vibrations.—The motion may be purely radial or partly radial and partly tangential. In the second case there will be an integral number of wave-lengths, and when this number is n we have the formula for the frequency

$$p^2 = (1 + n^2)\,\frac{E}{\rho_0}\,\frac{1}{a^2}$$

Putting $n =$ zero we find the frequency of the purely radial vibrations. The pitch of any mode of extensional vibration of the ring is of the same order of magnitude as the pitch of the corresponding longitudinal vibration of a bar of length equal to half the circumference, the formula for the latter being in fact derived by writing n^2 for $1 + n^2$. Class IV. Torsional vibrations.—The motion consists of an angular displacement of the sections about the elastic central-line accompanied by a relatively very small displacement of the points on this line perpendicular to the plane of the ring. When there are n wave-lengths to the circumference the frequency is given by the formula

$$p^2 = (1 + \sigma + n^2)\,\frac{\mu}{\rho_0}\,a^2,$$

in which μ is the *rigidity* of the material. There is one symmetrical mode for which n is zero, and since $2\mu(1 + \sigma) = E$, the frequency of this mode is $\frac{1}{2}\sqrt{2}$ of that of the radial vibrations. The pitch of the torsional vibrations is comparable with that for a straight rod of length equal to half the circumference, the formula for the latter being in fact derived by writing n^2 in place of $1 + \sigma + n^2$. Formulæ equivalent to those given in connection with Classes II. and IV. have been obtained by Mr. Basset (Proc. Dec. 1891), but he has not interpreted his results.

Entomological Society, February 8.—Mr. Henry John Elwes, president, in the chair.—The President announced that he had nominated Mr. F. DuCane Godman, F.R.S., Mr. Frederic Merrifield, and Mr. George H. Verrall as Vice-Presidents during the Session 1893–1894.—Mr. S. Stevens exhibited a specimen of *Chærocampa celerio*, in very fine condition, captured at light, in Hastings, on September 26 last, by Mr. Johnson.—Mr. A. J. Chitty exhibited specimens of *Gibbium scotias* and *Pentarthrum huttoni*, taken by Mr. Rye in a cellar in Shoe Lane. He stated that the *Gibbium scotias* lived in a mixture of beer and sawdust in the cellar, and that when this was cleaned out the beetles disappeared. The *Pentarthrum huttoni* lived in wood in the cellar.—Mr. McLachlan exhibited a large Noctuid moth, which had been placed in his hands by Mr. R. H. Scott, F.R.S., of the Meteorological Office. It was stated to have been taken at sea in the South Atlantic, in about lat. 28° S., long. 26° W. Colonel Swinhoe and the President made some remarks on the species, and on the migration of many species of Lepidoptera.—Mr. W. F. H. Blandford exhibited larvæ and pupæ of *Rhynchophorus palmarum*, L., the Gru-gru Worm of the West Indian Islands, which is eaten as a delicacy by the Negroes and by the French Creoles of Martinique. He stated that the existence of post-thoracic stigmata in the larva of a species of Rhynchophorus had been mentioned by Candèze, but denied by Leconte and Horn. They were certainly present in the larva of *R. palmarum*, but were very minute.—Mr. G. T. Porritt exhibited two varieties of *Arctia lubricipeda* from York; an olive-banded specimen of *Bombyx quercus* from Huddersfield; and a small melanic specimen of *Melanippe hastata* from Wharncliffe Wood, Yorkshire.—Mr. H. Goss exhibited species of Lepidoptera, Coleoptera, and Neuroptera, sent to him by Major G. H. Leathem, who had collected them, last June and July, whilst on a shooting expedition in Kashmi territory, Bengal. Some of the specimens were taken by Major Leathem at an elevation of from 10,000 to 11,000 feet, but the majority were stated to have been collected in the Krishnye Valley, which drains the glaciers on the western slopes of the Nun Kun range. Mr. Elwes remarked that some of the butterflies were of great interest.—Mr. G. F. Hampson exhibited a curious form of *Parnassius*, taken by Sir Henry Jenkyns, K.C.B., on June 29 last, in the Gasternthal, Kandersteg.—Mr. J. M. Adye exhibited a long series of remarkable varieties of *Boarmia repandata*, taken last July in the New Forest.—Mr. C. O. Waterhouse exhibited a photograph of the middle of the eye of a male *Tabanus*, showing square and other forms of facets, multiplied twenty-five times.—Mr. R. Trimen, F.R.S., communicated a paper entitled "On some new, or imperfectly known, species of South African

Butterflies," and the species described in this paper were exhibited.—Mr. T. D. A. Cockerell communicated a paper entitled "Two new species of *Pulvinaria* from Jamaica."—Mr. Martin Jacoby communicated a paper entitled "Descriptions of some new genera and new species of Halticidæ."

Linnean Society, February 2.—Prof. Stewart, President, in the chair.—On behalf of Mr. Thomas Scott, the Secretary read a report on the entomostraca from the Gulf of Guinea, collected by Mr. John Rattray.—Mr. H. Bernard gave an account of two new species of *Rhax*.—An important paper by Mr. Arthur Lister, on the division of nuclei in the mycetozoa, gave rise to an interesting discussion, in which Dr. D. H. Scott, Prof. Howes, and others took part.—This was followed by a paper on the structural differentiation of the protozoan body as studied in microscopic sections, by Mr. J. E. Moore. The meeting adjourned to February 16.

PARIS.

Academy of Sciences, February 6.—M. de Lacaze-Duthiers in the chair.—On the variations in the intensity of terrestrial gravitation, by M. d'Abbadie. Observations begun in 1837 at Olinda (Brazil), on the variations in the direction of gravitational force also made its constancy doubtful. Experiments on falling bodies revealed irregularities similar to those described (last number) by M. Mascart. The closed barometer employed by the latter may be termed a *brithometer*.—On the preparation of carbon under high pressure, by M. Henri Moissan (see article).—On the reproduction of the diamond, by M. C. Friedel. Remarks by M. Berthelot (see article).—On the pathogeny of diabetes; part played by the expenditure and the production of glycose in the deviations of the glycemic function, by MM. A. Chauveau and Kaufmann. The same inferiority of venous with respect to arterial blood, as regards the amount of sugar contained in it, occurs in all the deviations of the glycemic function produced by a lesion of the central nervous system. This inferiority is equally pronounced in the hyperglycemia resulting from the extirpation of the pancreas.—On the progress of the art of surveying with the aid of photography, in Europe and America, by M. A. Lausedat. Since 1888 a zone of twenty miles on each side of the Canadian Pacific Railway, in the neighbourhood of the Canadian National Park, has been surveyed with the aid of photography under the direction of Messrs. Deville, Drewry, and McArthur, at an average rate of 1040 square km. per annum for four men under great climatic disadvantages. The cost of the undertaking amounts to three dollars per square km.—Determination of the amount of carbonic oxide which can be contained in confined air, by means of a bird employed as physiological reagent, by M. N. Gréhant.—On the properties of faculæ; reply to a note by Mr. G. Hale, by M. H. Deslandres.—The probability of coincidence between solar and terrestrial phenomena, by M. G. E. Hale.—Note on an explicit expression of the algebraic integral of a hyperelliptic system of the most general form, by M. F. de Salvert.—On a generalisation of Bertrand's curves, by M. Alphonse Dumoulin.—On the surfaces which admit a system of lines of spherical curvature and which have the same spherical representation for their lines of curvature, by M. Blutel.—On semicircular interference fringes, by M. G. Meslin. Rectilinear interference fringes are sections of hyperboloids by planes parallel to their axis, the light being propagated in a direction at right angles to that axis. If the light proceeds along the axis, a screen perpendicular to it will cut circular sections, and the fringes will have the form of a circumference of which a greater or smaller arc will be seen accordingly as the two pencils overlap more or less. In practice these circular fringes were obtained by separating two of Bellet's half lenses and placing them one before the other in front of a very small hole illuminated by sunlight, such that the axis of the pencil passes through the optical centre of the two lenses. Under these conditions two pencils are formed from the same source of light, which may be made to show circular fringes by moving the lenses slightly in a direction perpendicular to their optical axes.—Study of the fluorides of chromium, by M. C. Poulenc.—On a new soldering process for aluminium and various other metals, by M. J. Novel. For aluminium the following solders are recommended: (1) Pure tin, fuses at 250°. (2) Pure tin 1000 gr.; lead 50 gr. (280° to 300°). (3) Pure tin 1000 gr.; pure zinc 50 gr. (280° to 320°). These solders do not stain or attack aluminium. A nickel soldering bit is preferable. (4) Pure tin 1000 gr.; red copper 10 to 15 gr. (350° to 450°). (5) Pure tin 1000 gr.; pure nickel 10 to 15 gr. (350° to 450°). These give a slightly yellowish tint, but are very durable. (6) Pure tin 900 gr.; copper 100 gr.; bismuth 2 to 3 gr. This is specially suitable for soldering aluminium bronze.—Action of acetic acid and formic acid upon terebenthine, by MM. Bouchardat and Oliviers.—On the mode of elimination of carbonic oxide, by M. L. de Saint-Martin. Experiment shows that animals partly intoxicated by carbonic oxide, when placed in conditions under which natural elimination is impossible, destroy slowly but regularly a certain quantity of the poisonous gas, this destruction being the more active the less the intoxication. It is probably converted into carbon dioxide. The toxic effect is entirely dependent upon the time during which the organism is exposed to the gas, and a very small quantity can be fatal on prolonged exposure.—Influence of pilocarpine and floridzine on the production of sugar in milk, by M. Cornevin.—On the seat of the colouring matter in the green oyster, by M. Joannes Chatin.—On pseudo-fertilisation in the *Uredinei*, by MM. P. A. Dangeard and Sapin-Trouffly.—On the substances formed by the nucleole in *Spirogyra setiformis*, and the directive force which it exerts upon them at the moment of the division of the cellular nucleus, by M. Ch. Decagny.—On a process for measuring the double refraction of crystalline plates, by M. Georges Friedel.—A horizontal section of the French Alps, by M. W. Kilian.—On the arrangement of the cretaceous beds in the interior of the Aquitaine basin, and their relations to tertiary formations, by M. Emmanuel Fallot.

MAN AND EVOLUTION.

Evolution and Man's Place in Nature. By Henry Calderwood, LL.D., F.R.S.E., Professor of Moral Philosophy, University of Edinburgh. (London: Macmillan and Co., 1893.)

THIS work appears to have been written for the purpose of setting forth the author's views as to the twofold nature and origin of man. He admits, fully and unreservedly, that both the bodily organism and the lower mental nature of man have alike been developed by a process of evolution from a lower animal form; but he urges with much force, and often with both eloquence and dialectic skill, that the rational and moral nature of man has not been thus developed.

The book, however, has many defects; and one cannot but feel that the writer has undertaken a task somewhat beyond his powers. Most prominent is its extreme diffuseness and vagueness, the want of systematic treatment, the frequent reiteration of the same ideas under different forms of words, and the misconceptions arising from want of familiarity with many of the subjects discussed. We are also annoyed by the frequent reference to problems to be discussed or solved, which are yet only hinted at or talked about later on. Thus, in the first chapter, we are told that a "fuller study of human life" is now required, and that the crowning effort of science in the study of Nature must be "the solution of the problem of man's appearance" on earth. Yet no attempt is made in the whole volume, either to solve this problem or even to show what progress has been made towards solving it. At p. 154 we are told that—"We are now ready for consideration of Darwin's argument"—as to the relation of the mental nature of man and the lower animals. And on the next page—"The direction to be followed now becomes more obvious"—after which we have pages of general remarks on the intelligence of the dog and the ant. Then, at p. 162—"The method to be followed is clear: we must compare the higher animals with man"—and —"careful comparison of the two orders of life is the only course open for scientific inquiry," and again,—"The difficulties belonging to such a mode of inquiry are many; but no easier method is available." Then, at p. 167, we find that Darwin "has at least suggested the essential conditions of our inquiry." After this we have another series of vague general remarks, till at p. 171 we find another statement of the mode of inquiry, and we are told that "we must have in full view all that is common to man, as animal, with the higher mammals, making account of close approximation in organic structure." Yet we nowhere find any attempt to apply these principles or methods so laboriously set forth, but are put off with such statements as—"In proof of exercise of intelligence, examples are many and familiar, making it unnecessary to enter upon detailed references." Then we are interrupted by fifteen pages of remarks on instinct among insects, although it has been repeatedly stated that the relation of man to the higher animals was the problem to be discussed; and at p. 193, we are told that—"Now at length, after careful survey of lower levels, we advance towards the height, on which the grand problems of intelligence become visible. Study of comparative intelligence now becomes possible." Then follow again page after page of what can only be described as "general remarks" on horses, dogs, monkeys, and other animals. We are told, for example—"When the higher animals are compared with the lower, it is clear that a power of intelligence must be attributed to the higher, which cannot be credited to the lower. Phenomena of domestication come to our aid here, confirming this generalisation." And a little further on, as a proof that dogs can interpret signs and act upon them, we have the following concrete illustration, among the very few in the book, and therefore we may presume it is considered a valuable one. "'Go home' will send one dog back, but the Gaelic equivalent alone will be effective in the case of a dog reared in the Highlands of Scotland, where the Celtic tongue is in common use." And then, as if the intelligent reader might doubt this astounding fact, the author adds, "Observation affords ample testimony for this."

Although the author has evidently read very widely on the subject of evolution, his want of grasp of the subject is continually shown. Thus, when discussing the struggle for existence, he seems to think that this is usually considered to be limited to a struggle for food. He says:—"A general view of the relations of life and environment will guard against interpretation of facts exclusively by reference to struggle for existence consequent on the relations of numbers to food-supply." . . . "Life is too rich in variety to find adequate explanation of its history in the mere balancing of our numbers with food-supplies." . . . "In no life is progress to be explained exclusively by reference to amount of food-supply" . . . "environment must be read much more largely than could be suggested by mere dependence on materials for nutriment" —the above passages all occurring in a single paragraph.

We have to thank the author, however, for the very clear manner in which he admits, and even enforces the application of evolution to man. He states this conclusion in several places. Thus, at page 261, we find the following:—

> "The novelty of the situation lies in this, that man's alliance with all animal life has been established with a clearness and fulness of representation never before possible in the history of the world. The long-hidden secrets of nature are disclosed, and, behold! man has his heritage among the beasts of the field. The discovery is indeed a large one; the demonstration has been worked out in minute detail till no place is left for doubt."

By far the best portion of the work is that which is its special feature—the discussion of the rational as contrasted with the mere perceptive and intelligent nature of man and of the lower animals. A few quotations will explain the author's views, and show him at his best.

> "The conditions of action are changed when rational self-direction comes into view. This change is so great as to amount to a complete contrast with all that has appeared in lower forms of life. Passion and appetite have not disappeared: they are present as before; but instead of determining conduct, a new exercise of power has appeared to control them. Life has here a duality within it, which has not been seen at any lower stage.

Life's history becomes in this way a history of conflict, of which no trace has appeared at any earlier point in natural history. The struggle between individuals has not disappeared, but a struggle within the individual life occurs, which has never been visible in the history of any inferior order of life" (p. 55).

Another aspect of the rational nature is thus defined:—

"The difference which severs man from the animals lies beyond the craving, and the cunning, and the consuming of what has been captured. We trace it in his plans for the day, in his preparation of his weapons, in his survey of the heavens, in his taking of reckonings for direction. He deals with the relations of means to ends; he utilises past experience in his reflections over what has happened; he reaches general conclusions" (p. 270).

Perhaps the finest passage in the book is at p. 287, tracing the moral element in the thought of all kinds of men and all diversities of race, as shown by the sense of wrong and injustice. We can only give here the concluding lines:—

"To this appeals the criminal in the heart of our surging crowds, placed under arrest, if he should be condemned on insufficient evidence. To this appeals every buyer in the market, defrauded by the thrusting of adulterated goods into his hands. And to this does every gentle one make appeal, defrauded in ways still worse, by false expressions of love, from whose falseness recoils a blighted life, bearing through long and weary years witness to the cruel wrong that has been done. Where, along the devious paths in which man is found, is justice not honoured, at least by outcry against harsh wrongs?"

There is much in this volume that will attract readers more disposed towards the esthetical and moral than towards the scientific aspects of evolution. Agreeing, as the present writer does, with most of the conclusions of the author, he can but regret that they have not been set forth in a manner more likely to attract scientific readers.

A. R. W.

POINCARÉ'S "THÉORIE MATHÉMATIQUE DE LA LUMIÈRE."

Théorie Mathématique de la Lumière. Par H. Poincaré, Membre de l'Institut. (Paris: G. Carré, 1889 and 1892.)

THIS work consists of two volumes, the first of which comprises a course of lectures delivered by the author in 1887–1888, whilst the second contains a further course delivered in 1891–1892.

The first volume commences with a discussion of the constitution of the luminiferous ether, in which the latter is regarded as a system of discret molecules in stable equilibrium under the action of molecular forces, and the author finally deduces equations of motion of the same form as those which are furnished by the ordinary theory of isotropic elastic media. He then adopts the hypothesis, originally due to Lord Kelvin, that the velocity of propagation of the longitudinal wave is practically zero. The principle of Huygens is next dealt with, and this is followed by a chapter on diffraction. A complete discussion of all the difficulties attending the resolution of waves would carry us too far, but the author does not appear to be acquainted with the masterly investigation of Sir G. Stokes, or the formula deduced by him, which gives the effect of an element of a plane wave at a distant point, and which enables the unsatisfactory reasoning on which the principle of Huygens depends to be dispensed with. The diffraction of light diverging from a focus is next discussed, and the intensity of light diffracted by a circular aperture or disc is obtained in the particular case in which the point of observation is the projection of the centre of the aperture or disc upon a screen; but no mention is made of Prof. Lommel's able investigation in the general case of an excentric point. A few stock problems relating to the diffraction of parallel rays are also discussed, but nothing is said about the resolving power of optical instruments, or the theory of gratings, including Prof. Rowland's ingenious invention of concave gratings.

Chapter V. commences with the theories which have been proposed to explain the photogyric properties of quartz and certain organic substances, and concludes with an account of some of the theories of *ordinary* dispersion. This is followed by a long chapter which begins with Fresnel's theory of double refraction, and then proceeds to discuss the theories of Cauchy, Neumann, Sarrau and Bousinesq.

In all these theories the ether is regarded as an æolotropic elastic medium, and in considering them the author is to be congratulated on having shown no sympathy with the small minority who regard the writing down of equations as a foolish process; but although during recent years much time has been spent in elaborating such theories, it may be questioned whether the majority of them have contributed any very substantial addition to scientific knowledge. The theory of the propagation of waves in an æolotropic elastic medium was rigorously investigated by Green as long ago as 1839; and although a theory of this kind is useful in enabling the mind to form a mental representation of the mechanism which is required to produce double refraction, it is well known that Green's theory, and all others of a similar character, fail to furnish a satisfactory explanation of this phenomenon. The principal defects of such theories are, that although most of them lead to Fresnel's wave surface, or to one which is a very close approximation thereto, they require us to suppose that the vibrations of polarized light are parallel instead of perpendicular to the plane of polarization; and they also fail to give results which explain crystalline reflection and refraction, unless certain additional assumptions of a very questionable character are made. Probably it will not be thought an exaggeration to say, that the only theory of elastic media which satisfactorily explains double refraction is the one which is due to the joint labours of Lord Rayleigh, Lord Kelvin, and Mr. Glazebrook.

At the commencement of Chapter VII., which deals with reflection, the following statement is made (see p. 320):—

"La réflexion vitreuse a donné lieu à trois théories également confirmé par l'expérience, ce sont celle de Fresnel, celle de Neumann et MacCullagh et celle de Cauchy."

The theories of Neumann and MacCullagh depend upon the hypothesis that the *density* of the ether is the same in all media, and that it is the rigidity which varies; and it is somewhat surprising that M. Poincaré does not appear to be aware of the investigations of Lorenz and Lord Rayleigh, who completely exploded this hypothesis twenty years ago by showing that it leads to two polarizing angles. The weak point in the investigations of most French mathematicians on the subject of reflection and refraction arises from the fact that, in consequence of their not having made a careful study of Green's papers and the subsequent developments by Lord Rayleigh and Lord Kelvin, they are unable to deal satisfactorily with the longitudinal or pressural wave. The difficulties arising from the existence of these waves may be got rid of either by assuming, as Green did, that the ratio of the velocity of propagation of the longitudinal wave to that of the transverse wave is very large, or, by adopting Lord Kelvin's hypothesis, that the above ratio is very small; but it cannot be too emphatically stated that the existence of such waves must not be disregarded, and that any attempt to ignore them will inevitably end in failure.

This chapter concludes with a brief account of metallic reflection, in which the author has adopted the equations of motion given by Voigt. The chief difficulty in trying to explain metallic reflection, by the introduction of a viscous term into the equations of motion, is due to the fact that Eisenlohr has shown that for certain metals the pseudo-refractive index is a complex quantity whose real part is negative.

Turning now to Volume II., which consists of a further course of lectures delivered in 1891–1892, we find that it commences with the theory of isotropic elastic media in its ordinary form. Next follows a chapter on the electromagnetic theory, in which the author confines himself to the case of an isotropic medium, and has given no account of the investigations of Glazebrook on crystalline reflection and refraction, in which it is shown that the intensities of the reflected and refracted waves satisfy the same equations as those deduced many years previously by MacCullagh from an erroneous theory, but which nevertheless explain the facts in a fairly satisfactory manner. M. Poincaré assumes that the vector potential satisfies the solenoidal condition; but although the employment of the vector potential is valuable as a mathematical artifice, its use requires extreme care, inasmuch as it contains an undetermined quantity; and I believe it can be proved that in certain cases the solenoidal condition is not satisfied. In the electromagnetic theory of light this difficulty can always be evaded by eliminating the vector potential from the equations, which is the preferable course to pursue.

In Chapter V., after discussing ordinary reflection and refraction, the author attempts to construct an electromagnetic theory of metallic reflection and refraction by taking into account the conductivity. This theory leads to Cauchy's formulæ, but requires that the real part of the pseudo-refractive index should be positive, whereas Eisenlohr has shown that for certain metals these formulæ cannot be reconciled with experiment unless the real part is negative. In the case of steel this quantity is positive throughout the whole range of the visible spectrum; but as thin films of iron, when magnetized, exhibit anomalous dispersion, it is doubtful whether this hypothesis is satisfactory even in the case of steel or iron.

The next four chapters are devoted to the principle of Huygens and to diffraction; and in Chapter X. the author has discussed Von Helmholtz's theory of anomalous dispersion. The advantage of theories of the class to which that of Von Helmholtz belongs is, that they endeavour to account for dispersion and absorption by taking into account the mutual reaction between ether and matter, and show that when one or more of the free periods of the vibrations of the matter coincides with one or more of the free periods of the rays of the spectrum, absorption and anomalous dispersion will be produced. By the aid of this theory the absorption produced by sodium vapour may be accounted for, as well as the anomalous dispersion and selective reflection produced by fuchsine and other aniline dyes. The author has not, however, developed the consequences of this theory as far as might be done.

It is not unnatural that M. Poincaré should have given special prominence to the writings of his own countrymen; his treatise would, however, have been much improved had he not confined himself so exclusively to the writings of French mathematicians, but had given a fuller account of the work done by mathematicians of other nationalities.

A. B. BASSET.

THE MOTHS OF INDIA.

The Fauna of British India, including Ceylon and Burma. Published under the authority of the Secretary of State for India in Council. Edited by W. F. Blanford. "Moths." Vol. i. By G. F. Hampson. (London: Taylor and Francis, 1892.)

MR. HAMPSON is already favourably known to entomologists by his work on the "Lepidoptera Heterocera of the Nilgiri District," which forms Part viii. of the series of "Illustrations of typical specimens of Lepidoptera Heterocera in the collection of the British Museum." In the work before us he has undertaken a far more important task; nothing less than a descriptive handbook of the moths of India, which, when complete, will prove as useful to Indian entomologists as the well-known work on the butterflies of India by Marshall and De Nicéville.

Hitherto the available information on the moths of India has been scattered over a great variety of books and periodicals, far too numerous and costly to be easily available out of London or Calcutta, and extremely difficult to use satisfactorily, even if accessible. But Mr. Hampson has been given the fullest facilities for examining all the principal public and private collections of Indian moths, from that of the British Museum downwards, and has also made free use of the libraries of the British Museum at South Kensington, which now contain the finest series of entomological books in the world; and the result is a work which can hardly fail to give an enormous impetus to the collection and study of Indian moths.

Much attention has been paid to the classification of moths, and the introductory pages are occupied with details of structure, illustrated by woodcuts of parts of the head, antennæ, legs, and neuration. This is followed by a genetic tree of the families of moths, and by a tabular key based chiefly on neuration and antennæ. Mr. Hampson admits thirty-four families of Indian moths, of which the first twenty-three, including 1158 species, are dealt with in the volume before us. The earlier families of moths are, however, much less numerous in species than the later ones, and it must not be supposed that Mr. Hampson has dealt with anything like half the Indian species in his first volume, which comprises the series of families usually classed under Sphinges and Bombyces, extending, according to the author's classification, from *Saturniidæ* to *Hypsidæ*. The important Bombycide families, *Arctiidæ*, *Agaristidæ*, and *Uraniidæ*, are, however, relegated to the second volume, while several families of more or less doubtful position find a place in vol. i., such as the *Cymatophoridæ*, *Thyrididæ*, *Sesiidæ*, and *Tinægeriidæ*. We observe that Mr. Hampson closes the series of moths with the *Tineidæ*, *Pterophoridæ*, and *Alucitidæ*, and in this adopts the usual classification, though in the main he has struck out an entirely new classification of his own, and the very first innovation which meets the eye is the novelty of commencing the moths with the *Saturniidæ*.

We hope that Mr. Hampson will take an opportunity of discussing the various systems of classification of moths which have been proposed by Guenée, Herrich-Schäffer, Plötz, and other entomologists, not forgetting the strange system proposed by Zebrawski, in his work on the Lepidoptera of Cracow, in which the butterflies are placed in the middle instead of the beginning of the series of Lepidoptera. Such a discussion would be unsuitable in the present work, but if published elsewhere might be very useful.

Long descriptions of genera and species in a work of this character would have been out of place, and we are glad to find that they have been avoided. Each family or subfamily is succinctly characterised, and usually illustrated by a figure of the larva. This is followed by a tabular key to the genera, and then by a notice of the genera and species. The notice of each genus consists of synonymy, type, range, and a brief indication of the principal characters. That of the species includes synonymy, description, including both sexes, and transformations when necessary, range and expanse. An excellent woodcut is usually given of one representative of each genus, showing the wings and body on one side, and the neuration on the other, extra figures of antennæ and legs being sometimes added.

No book, however useful or carefully compiled, can be free from errors, but these cannot be detected at a glance, and the only technical mistake of importance which we have noticed in turning over Mr. Hampson's work is that the broad-bordered Australian *Macroglossum kingii*, Macl., is included among the synonyms of the narrow-bordered *Cephonodes hylas*, Linn.

Much, no doubt, remains to be said about Mr. Hampson's classification, his use of generic names, and his placing together insects regarded as distinct by other authors as synonyms. But these are all points admitting of great difference of opinion, and we do not propose to discuss them further in the present notice.

We should add that various new families, besides many new genera and species, are described by Mr. Hampson for the first time. W. F. K.

OUR BOOK SHELF.

The Year-Book of Science (for 1892). Edited by Prof. T. G. Bonney, D.Sc., LL.D., F.R.S. (London: Cassell and Co., 1893.)

ALL interested in scientific progress will welcome the appearance of the second volume of this useful year-book. The staff of contributors includes such names as Dr. Ramsay, Prof. Seeley, Mr. Botting Hemsley, &c., and the accuracy of the summaries of the year's developments may therefore be thoroughly relied upon. The plan of the volume follows closely on the lines of its predecessor, but it has been extended so as to include geographical and anthropological matters, and zoology has received more complete treatment. If one may judge of the activity in different departments of science by the space required for the account of their progress, electricity and organic chemistry would appear to take the lead. As in the last volume, no attempt has been made to present a complete catalogue of papers. The object has been simply to select the memoirs of exceptional interest; and so far as we have been able to judge, the selections have been judicious. An excellent index of subjects, and one of authors, complete what will no doubt be found a very useful volume.

Treatise on Thermodynamics. By Peter Alexander, M.A. Pp. xii, 203. (Longmans, Green, and Co., 1892.)

THIS is in many respects a singular work. Whole pages, we may almost say whole sheets, are devoted to the multiplication of elaborate proofs of intrinsically simple theorems for which a few lines would be ample allowance, while some of the real difficulties of the subject are but lightly touched on. The other special characteristics, so far as we have seen, are three in number. First, and most prominent, the extraordinary proportion of formulæ to text, which gives the whole the look of a treatise on Partial Differential Coefficients rather than on a branch of Physics. Second, the fearful and wonderful collection of names for special cycles, *e.g. Isothermentropicycle*, *Isobarymegacycle*, *Isenergentropicycle*, &c. Finally, the expressions of doubt or hesitancy with which many steps, universally recognised as valid, are introduced. In the first and second of these characteristics the author far transcends the results of the licence willingly allowed to pioneers like Clausius and Rankine. But these have been (at least in great part) long since discarded, and can never be reintroduced. The third characteristic is, to say the least, not precisely one to be desiderated in a text-book, where we naturally expect to find some slight trace of "Sir Oracle."

Mediæval Lore: an Epitome of the Science, Geography, Animal and Plant Folk-Lore and Myth of the Middle Ages. Being Classified Gleanings from the Encyclopædia of Bartholomew Anglicus on the Properties of Things. Edited by Robert Steele. (London: Elliot Stock, 1893.)

THE original work of which parts are translated in the present volume, may be said to have a place of its own in the history of European literature. It was written in the thirteenth century, and the Latin text was soon widely appreciated, while in the course of the fourteenth century it was translated into French, Spanish, Dutch, and English. The book is full of interest, for it presents a summary of all that was known in the Middle Ages about man and the world. The change which has been gradually effected by the use of modern scientific methods is, of course, incalculable; but some readers will probably be surprised to find to how large an extent Bartholomew mingles the results of shrewd and accurate observation with quaint fancies and unverified judgments. The present volume consists of selections from the edition of Berthelet, 1535; and the good style of the translator adds greatly to the charm of the author's philosophy and science. Mr. Steele has done his work with much tact and care, and an interesting preface is contributed by Mr. William Morris.

Astronomy for Every-day Readers. By B. J. Hopkins, F.R.A.S. (London: George Philip and Son, 1893.)

THIS is a little book which aims at explaining in "as accurate and interesting a manner as possible such of the phenomena of the heavens as should be known to every intelligent person." It consists of six chapters dealing respectively with day and night, the phases of the moon, the tides, the seasons, eclipses, meteors, shooting stars, and comets. Descriptive astronomy is not touched upon, but there is an introductory chapter giving a general survey of the solar system and its dimensions. The book has been very carefully written, and the scientific explanations are much relieved by interesting references to the history of the subject. The author has succeeded in giving very clear and concise accounts of the every-day phenomena with which the book specially deals, and it seems well adapted to awaken a desire for more in the class of readers to whom he more particularly appeals. A biography of the author—who is described as "the working-man scientist"—is also included.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Blind Animals in Caves.

IN an article in the current number of the *Contemporary Review* Mr. Herbert Spencer discusses the "familiar instance" of blind animals in caves as bearing upon the hypothesis of the transmission of acquired characters. Mr. Spencer is not satisfied with the explanation of the blindness of these cave animals offered by Weismann, who endeavours to account for them by two conditions recognised as operating in regard to other cases by Darwin, viz. cessation of selection and parsimony of growth ("Origin of Species," sixth edition, p. 118), of which the former author has treated under the name Panmyxia. Mr. Spencer shows that the saving of ponderable material in the suppression of an eye is but a small economy: he loses sight of the fact, however, that possibly, or even probably, the saving to the organism in the reduction of an eye to a rudimentary state is not to be measured by mere bulk, but by the non-expenditure of special materials and special activities which are concerned in the production of an organ so peculiar and elaborate as is the vertebrate eye.

That, however, to which I wish here to draw the attention of Mr. Spencer and his readers is this:—Mr. Spencer appears to think that if he disposes of Weismann's explanation of the blindness of cave-animals according to "Panmyxia"—there remains only the explanation by "transmission of acquired characters" in the field. He appears not to be acquainted with the explanation which I have offered of the blindness of cave-animals. It is closely similar to that given by Darwin of the occurrence of wingless insects on oceanic islands. My explanation consists in an application to the case in hand of Darwin's principle of "natural selection." I published it some years ago in my article "Zoology" in the "Encycl. Britannica," reprinted in 1890 in a volume of essays, bearing the title "The Advancement of Science." My suggestion was (and is) as follows, and I should like to see what Mr. Spencer has to say to it:—"This instance (that of the blind cave-animals) can," I wrote in the article above-named, "be fully explained by natural selection acting on congenital fortuitous variations. Many animals are thus born with distorted or defective eyes whose parents have not had their eyes submitted to any peculiar conditions. Supposing a number of some species of Arthropod or Fish to be swept into a cavern or to be carried from less to greater depths in the sea, those individuals with perfect eyes would follow the glimmer of light and eventually escape to the outer air or the shallower depths, leaving behind those with imperfect eyes to breed in the dark place. A natural selection would thus be effected. In every succeeding generation (bred in the dark place) this would be the case, and even those with weak but still seeing eyes would in the course of time escape, until only a pure race of eyeless or blind animals would be left in the cavern or deep sea."

My own position in regard to the hypothesis of the transmission of acquired characters remains what it was ten years ago, viz. that in the absence of observed instances of this transmission and in the presence of repeated observation that particular acquired characters are *not* transmitted, I do not consider it legitimate to *assume* a transmission of acquired characters as the explanation of any given case, such, for instance, as that of the blind cave-animals. I am confirmed in this attitude by the fact that a little consideration has enabled me and others to explain satisfactorily, by reference to no hypothetical causes, but to the admitted and demonstrable facts of "congenital variation" and "natural selection," instances brought forward as "only to be explained on the assumption of the truth of Lamarck's hypothesis."

On the other hand, I have always considered that there is not sufficient ground for asserting that a transmission of acquired characters *can not* take place. The important question is still as it was five years ago, "*Does* it take place?"

Oxford, February 14. E. RAY LANKESTER.

Glacier Action.

I HAVE read with great interest and pleasure the short review in your paper of last week by Prof. Bonney, giving a summary of the results of a survey of the French freshwater lakes, and indicating as the most probable conclusion that they cannot be accounted for on the theory of the late Sir A. Ramsay, by the digging-out power of glaciers.

Living as I do in a highly glaciated country, and in a country also full of lakes, both fresh and salt, I have never believed in that theory. Lakes seem to me to be due to the same causes which have produced the glens and hollows in which they lie, and these causes cannot be identified with glacier action alone. The theory of Ramsay attributes to glacier action powers and effects which have never been proved to belong to them. Glaciers do not dig out. They rub down—abrade—and scoop, when they are moving down inclined planes at angles more or less steep. But when they reach level ground they do not dig; they rest upon the level surfaces, and when pressed from behind they flow over it. But I have never seen any proof that they can act like a ploughshare, or rather like one of the new digging machines.

In so far as all existing glens may have been formerly occupied by glaciers, their depths must have been increased by glacier action, on the supposition that they were tilted, or upraised at some angle required for this form of true glacier action. On this supposition, indeed, lake basins may be said to be partly due to glaciers. But then this supposition involves and depends upon the assumption that earth movements have made the lake basins what they now are—hollows in a comparative level.

Like all other general theories in the history of geology, the "glacial theory" seems to me to have been ridden to the death, and I have been long waiting for some signs of that reaction or correction which is still much needed. I hold that in this country there is not only no evidence of "ice sheets" overriding all the hills, but the strongest evidence against such sheets. Our glens had true glaciers in abundance, no doubt, and they have left their tool-marks very distinctly. But those marks are quite inconsistent with one universal ice-cap or ice-sheet over all the land. ARGYLL.

Inveraray, February 16.

Dr. Joule's Thermometers.

EVERY one will, I am sure, be glad to know that Dr. Joule's thermometers are under investigation by Prof. Schuster.

It is unfortunate that Joule does not give the actual readings of the freezing point, but if the comparison quoted by Rowland was made in either 1879 or 1890 it may be that he referred to the reading of November, 1879, when the total rise of the zero point was 12·92 scale divisions. In that case the original reading in April, 1844, would be 9·70; at any rate this number cannot be very far from the truth.

The temporary changes of zero point alluded to by Prof. Schuster certainly complicate the matter, but from the numbers given it would appear that since 1879 or 1880 there has been a further secular rise of from 0·38 to 0·89 of a scale division. Nothing is said in Joule's paper about the temperatures at which the thermometers had been kept before the readings of the freezing point were taken, but as the later observations—and most of the earlier ones—were made in the winter months, it may perhaps be assumed that the temperatures were nearer 7° than 30°, and that the actual reading on the scale last winter should be taken as nearer 23·51 than 23·00. If this is so the total rise of the zero point last winter would be nearer 13·81 than 13·30.

Prof. Schuster states that "with properly annealed thermometers the secular changes are much smaller than the temporary ones," and that is no doubt true for observations extending over a limited time and with such comparatively large variations of temperature as from 7° to 30°. It may be pointed out, however, that the secular rise since 1879 or 1880 is probably greater than the maximum temporary change recorded by Prof. Schuster, and of course the total secular rise is enormously greater.

It may be true that the secular changes of a thermometer gradually vanish, but it must, I think, be conceded, that in the case of Dr. Joule's thermometer it will be a long time before absolute constancy is attained. There can be no doubt that even now, nearly forty-nine years after the first reading was taken, the zero point is still rising, and it does not appear to me to be very improbable that during the next fifty years there may be a further rise of two scale divisions, the amount calculated from the purely empirical formula which I have suggested.

Foraminifer or Sponge?

UNDER the above heading in last week's NATURE Dr. Hanitsch briefly draws our attention to Mr. A. Goës' report on the deep sea organisms procured by Prof. Agassiz in the American tropical Pacific, which he describes as Arenaceous Foraminifera, with the name *Neusina Agassizi*.

As it was from me that Dr. Hanitsch received the specimens he describes, which I had after a personal conversation on the matter sent him, for his opinion as to their relation to true sponges, I venture to send some further observations on these interesting forms.

Dr. Hanitsch is, I believe, quite right in referring Mr. Goës' Neusina to Prof. Haeckel's *Stannophyllum zonarium*, as described in his report on the *Challenger* deep-sea Keratosa. But while admitting my admiration of Prof. Haeckel's wonderful production on the *Challenger* specimens, I do not agree with him as to their being true Keratose sponges.

My conclusion is based upon the examination of nearly the whole *Challenger* collection, and in not one species could I find the slightest trace of any of the flagellated chambers characteristic of sponges.

Prof. Haeckel accounts for the absence of this important feature through the bad preservation of the specimens. Yet he describes the most delicate parts of a commensal Hydroid in full, and was able to observe amœboidal cells, and the granulated sarcode bodies peculiar to all bottom living Foraminifera.

If, however, the forms described by Prof. Haeckel prove after all to be true Keratose sponges, the present state of our knowledge does not justify their separation from such recognised genera of Foraminifera, as Masonella, and Syringammina of the late Dr. G. Brady; Technitella, Haliphysema, and Marsipella of Canon Norman; or *Hyperammina palmiformis*, described by myself from the Faröe Channel, all which forms have the power of forming siliceous and chitinous skeletons.

Without going into further detail here it will be readily understood that I quite agree with Mr. Goës in placing these organisms among the Foraminifera, although it would have been better had he given us a clearer and more detailed description of his Neusina.

I had hoped to have published my personal observations on these most interesting organisms, but circumstances have prevented me doing so up to the present.

I for one would be glad if Dr. Hanitsch would give his opinion as to their supposed sponge structure, which he has not done in his previous letter.

F. G. PEARCEY,
Late of the *Challenger* Expedition and Commission.

Owens College Museum, Manchester.

Colonial Meteorology.

ON p. 363 of your last number your reviewer of the "Year-book of the Imperial Institute," after remarking that "climate certainly deserves better treatment," continues:—

"We do not think space would be wasted in giving the mean monthly temperatures and rainfall for the average year and for two extreme years, at a few representative stations in the larger colonies. This information cannot indeed be found in any existing books, but must be worked out from original records, which exist abundantly, and are rarely made available to practical workers."

I am afraid that the reviewer does not always read NATURE, for you, sir, have on several occasions noticed my efforts in this direction, efforts which have gone on uninterruptedly for twenty years. As, now that you have taken the matter up, it is not improbable that some of the funds lavished on the Imperial Institute may be devoted to the subject, and my small organisation be swamped or superseded, I hope that you will, in justice to the directors of the various Colonial observatories who have helped me for so many years, and as some consolation for the entire ignorement of our organisation by your reviewer, allow me to give its history in the fewest words possible.

In 1873 I determined to try to publish monthly a table giving the principal climatic data for each synchronous month at widely spread stations over the entire British Empire. The leading idea was identity, so as to ensure comparability. I therefore prepared some blank forms and sent them with a circular letter to about twenty of our leading Colonial meteorologists. Every one without exception promised to help, and it says much for colonial climate to add that during the subsequent twenty years not more than five or six of my original correspondents have passed away.

During the period occupied in the transit of my request and of the replies thereto, I wrote a series of short articles pointing out the leading features, and as far as practicable the mean values, for the various stations, so that when we began publishing the monthly values, the departures from the mean could be recognised. These articles and the tables themselves from 1874 to 1881 appeared in *The Colonies* (subsequently *The Colonies and India*). When in 1882 that paper passed into other hands, the proprietors declined to publish the tables, and I began to insert them in the *Meteorological Magazine*, where they have appeared regularly month by month for the subsequent thirteen years. At the close of each year an extra table is given with a summary of the results for the year, and NATURE has often done me the honour of quoting portions of these summaries.

I enclose copy of our last table, and though I know that to reproduce it would be to make a somewhat large demand upon your space, I feel that the work (wholly unpaid, be it remembered) of my Colonial friends during these past twenty years, claims some consideration and some recognition. You will see by the signatures that the authorities are the highest attainable.

Ozone.

WITH reference to a paragraph in NATURE, p. 373, on observations of ozone in the atmosphere, and the paucity of observers and records, I may be allowed to state that I have collected sets in the North Atlantic and Pacific Oceans and Mediterranean. These have been taken by officers of the Royal Navy and mercantile marine at sea, and some of the records have been tabulated, and may be communicated to some society in due course. Moffatt's papers, made by Negretti and Zambra, have been used throughout, so the observations are all uniform and comparable.

LION-TIGER AND TIGER-LION HYBRIDS.

THE Council of the Royal Zoological Society of Ireland entertain some hope that it will be possible to produce in their Gardens examples of hybrids or cross-breeds between the two largest species of cat, namely, the lion and tiger.

That such hybrids have been produced is a matter of historical record, and as the writer is particularly interested in the success of the experiment now in progress in the Dublin Gardens, where over one hundred lion cubs have been successfully reared, he thinks it desirable to record all the details which he has been able to collect on the subject.

So far as can be ascertained the only lion-tiger cubs, as they have been called, which were ever produced belonged to several distinct litters by different parents, perhaps, but in the same menagerie—that of F. Atkins, of Windsor.

The father of the first litter of these cubs was a lion bred in Atkins's menagerie, the head-quarters of which were at Windsor. The mother was an imported tigress. From Griffith's account ("Animal Kingdom," vol. ii. p. 448, 1827) it would seem that the lion and tigress were about two years together, in the same cage, before any issue appeared. The first litter, consisting of three cubs, was born at Windsor on October 17, 1824—being the result of a particular intercourse which lasted for ten or twelve days in the beginning of the previous July. The cubs were shortly afterwards exhibited to his Majesty, who, according to the showman's own handbill—a copy of which has been lent to me by Dr. William Frazer—christened them lion-tigers. The lion died six weeks afterwards, and the cubs, as related by Griffith, were fostered by several bitches and a goat, and it was expected would attain to maturity; but although there is no clear intimation as to the exact date when this was written, the figures of the cubs accompanying the account are said to represent them at the age of only about three months. It is stated by one writer, however, that they did not attain to maturity ("English Cyclopædia Nat. Hist.," vol. ii. p. 763, art. "Felidæ," 1854).

The next litter was born at Edinburgh on December 31, 1827, according to Atkins's showbill and Sir William Jardine's works.[1] There were two cubs, and it would seem that they were exhibited together with, and therefore probably reared by, the mother, in the same den; but whether she were the same tigress as the mother of the previous litter is not clear.

They were seen by Sir William Jardine in September, 1828, and his figures may have been taken from them; but it has some resemblance in details, though not in general pose, to the figures published by Griffith of the 1824 litter. It would seem that Sir William was under the impression that it was these very cubs which were subsequently exhibited together with their parents in the same cage in the autumn of 1829. But there is a difficulty in accepting this conclusion, because the stuffed specimens of these two cubs still exist—one in the British Museum (Natural History) and the other in the Science and Art Museum, Edinburgh. I have recently had opportunities of examining both, and I should be inclined to think that the cubs were not *more* than about nine or ten months old when they died. So that either the cubs seen in 1829 were born subsequently to December 31, 1827, or the stuffed cubs just referred to must have been born previous to that date. That the cub in the British Museum was presented by J. Atkins, of Windsor, is attested by Dr. Gray's "Old List," page 40, which, through the courtesy of Dr. Günther, I have been able to consult.

That the specimen in Edinburgh was one of those born in 1827, and figured by Sir William Jardine, is, indeed, stated in the "English Cyclopædia," which adds that the cubs of that litter died young. Hence, it seems most probable that the cubs seen in the autumn of 1829 belonged to a subsequent litter, as has been suggested above. Further, Mr. J. G. Robertson, formerly of Kilkenny, has informed me that he saw a lion, tigress, and their three hybrid cubs in one cage in Kilkenny, where they were brought by a showman about the year 1832. They were the sole stock of the show.

Accordingly, it seems that besides the definitely attested births of the years 1824 and 1827, there were also, probably, some others. One of the accounts states that there is no great difficulty in promoting the union of the two species.

Besides the cub already referred to as having been presented to the British Museum by J. Atkins, I have also been shown by Dr. Günther unmounted skins of two reputed hybrid lion-tiger cubs, which are said in Dr. Gray's list to have been purchased from a dealer named Mathur, in 1842. They cannot, I think, have survived more than two or three days after birth, and their markings are too indistinct to justify any special description, particularly as their parentage is not more definitely attested. But it is of some importance to place on record here what is said as to the markings of the cubs first referred to. The specimens in the British and the Edinburgh Museums are both somewhat faded. In Gray's list the former is thus described: "Hybrid cub between lion and tigress; yellow; back slightly waved; limbs and tail banded with black."

Sir William Jardine merely says the general colour was not so bright as that of the tiger, and the transverse bands were more obscure.

Griffith describes the cubs he figured as follows:—

"Our mules, in common with ordinary lions, were born without any traces of a mane, or of a tuft at the end of the tail. Their fur in general was rather woolly; the external ear was pendant towards the extremity; the nails were constantly out, and not cased in the sheath, and in these particulars they agreed with the common cubs of lions. Their colour was dirty yellow or blanket colour: but from the nose over the head, along the back and upper side of the tail the colour was much darker, and on these parts the transverse stripes were stronger, and the forehead was covered with obscure spots, slighter indications of which also appeared on other parts of the body. The shape of the head, as appears by the figures, is assimilated to that of the father's (the lion); the superfineness of the body on the other hand is like that of the tigress" (p. 449).

Prof. R. H. Traquair, F.R.S., keeper of the natural history division of the Edinburgh Museum, has kindly had a photograph taken of the specimen above referred to prepared for me, and the transverse markings are distinctly visible in this picture.

I am tempted to conclude this record with an extract from Atkins's somewhat quaintly-expressed handbill, which does not bear any date, but probably belonged to the year 1828. The greater part of the bill consists of a long poetical description of the family with "a tigress their dam, and a lion their sire," and of the numerous distinguished persons who had paid them a visit. The following prose portion will probably be sufficient to extract from what is possibly one of few still existing copies of the handbill.

"ATKIN'S IMMENSE MENAGERIE.

"WONDERFUL PHENOMENON IN NATURE.

"*The singular, and hitherto deemed impossible, occurrence of Lion and Tigress in one den.*

"Cohabiting and producing young, again took place in this menagerie, on the 31st of December, 1827, at the City of Edinburgh, when the royal tigress brought forth two fine cubs!! And they are now to be seen in the same den with their sire and dam. The first litter of these extraordinary animals were presented to our most gracious Sovereign, when he was pleased to express considerable gratification, and to call them lion-tigers, than which a more appropriate name could not have been given. The great interest the lion and tigress have excited is unprecedented; they are a source of irresistible attraction, especially as it is the only instance of the kind ever known of animals so directly opposite in their dispositions forming an attachment of such singular nature. Their beautiful and interesting progeny are most admirable productions of nature. The group is truly pleasing and astonishing, and must be witnessed to form an adequate idea of them. The remarkable instances of subdued temper and association of animals to permit the keeper to enter their den, and to introduce their performance to the spectators, is the greatest phenomenon in natural history."

V. BALL.

OBSERVATIONS OF ATMOSPHERIC ELECTRICITY IN AMERICA.[1]

THE meteorological official of the United States known as "The Chief Signal Officer" has sanctioned the publication of this voluminous report of 320 quarto pages, embodying the result of a widespread photographic record and direct reading of atmospheric electrometers carried out under the auspices of the United States Government during the years 1884 to 1888, with the immediately utilitarian object of ascertaining how far it was possible to use electrical indication in weather prediction. As Mr. Mendenhall says, "No studies or investigations which did not bear upon this question were [considered] proper or allowable."

Although thus limited in scope the actual observations made and here recorded can hardly fail to be of service to future investigators into this obscure subject.

The report begins with a historical introduction, in which it is admitted that electricity was first purposely drawn from the clouds in France by Buffon and D'Alibard about a month before Franklin tried his already projected experiment; and that de Saussure was one of the first to obtain fairly quantitative results and to detect a diurnal period.

Volta "hit upon the capital device of a burning match" to replace the previous feeble collecting devices such as a bullet and wire shot up into the air. But nothing really exact and continuous was done "until Sir W. Thomson attacked the problem." He introduced the quadrant electrometer and the water-dropper, which have been the universal recording instruments ever since.

In fact "the work of Palmieri on Mount Vesuvius constitutes perhaps the only extensive series of observations in which instruments founded on the original design of Sir W. Thomson have not been used."

In the States the first energetic and influential mover in the direction of a serious record appears to have been Prof. Cleveland Abbé, who got himself authorised in 1880 by the Chief Signal officer to consult with Prof. Rowland on the subject, and afterwards with Prof. Trowbridge, and to make arrangements for a series of effective observations. Under the auspices of these gentlemen a staff of observers were trained and suitable instruments obtained, tested, and improved. Various collectors were tested, and in 1883 a photographic registration apparatus of M. Mascart was put into operation. In 1884 Mr. Mendenhall "was appointed to assume the direction of the work as chief of the physical laboratory and instrument division of the office in Washington." Stations were established in Washington, Baltimore, Boston, New Haven, Ithaca, and Ohio.

Much work was done in connection with electrometers by McAdie and McRae, but this is incorporated in the article "Electrometer" of the "Ency. Britt."

The instrument ultimately adopted was a quadrant electrometer of the Mascart pattern with special improvements, and was constructed by the Société Génevoise. A picture of it is given.

The method of connecting the quadrants to the two equal halves of a water battery, so that they might always be at equal opposite potentials, and of attaching the needle to the collector, was after many trials adopted; partly because higher insulation was thus possible, partly in order to get a straight line law. Deviation from this, due to what is called the "electric directing couple," is not overlooked, but by a stiff suspension and small range it is minimised.

An interesting chapter is that on "collectors." The water-dropper was mostly used, but its freezing is apt to interrupt the record. "Sergeant Morrill experimented on a special flame collector," supplied with gas at constant pressure and arranged so that wind could not extinguish it, and "before the termination of the work obtained very satisfactory results." But in order to secure uniformity between different stations he also designed a mechanical collector—a clockwork machine with revolving arm and intermittent contacts, which is virtually a gigantic replenisher, utilising the atmospheric potential as an inductor, and thereby feeding the electrometer up to the same potential. It seems to be as quick in response as a water-dropper (an important point, as some of the fluctuations of potential are very rapid), but "as it was only completed towards the end of the period of observation nothing very definite can be said of its performance." An illustration of the ingenious device is given in detail.

Observations.

Preliminary records are given showing the curves got at a roof station and a balcony station, also at different observatories in the same town. Some also from the top of the Washington Monument, which naturally show far greater potential and changes than the instrument in the Signal Office.

There are plotted a number of zigzags obtained from the different stations about the States, and very complicated and entangled the record is. None of the stations show any agreement; and, particularly at Ithaca, the electrometers seem usually to have been in a wildly excited state.

But during an Aurora on May 20, 1888, they were singularly quiet, and the remark is made: "It will be observed that the indications of the electrometer were positive during the day and night, and that no unusual fluctuations occurred."

The atmospheric potential is usually positive, and it has been often thought that a change to negative signalised bad weather. Certainly this does frequently happen; sufficiently often to make it worth while specially to examine this point; and several curve charts are given to show that "negative electricity in clear weather was observed at most if not all of the Signal Service Stations on numerous occasions during the progress of the work. In many cases precipitation occurred at points 10 to 100 miles distant, but in others clear weather prevailed over almost the entire country. A number of instances of negative potential during clear weather occurred at Ithaca, where careful attention was given to the matter of special observation by Mr. Schultze."

Effect of Dust, Haze, Fog.

"The effect of dust, haze, smoke, &c., in producing negative potential has been noticed by more than one observer. [Query whether the negative potential can have ever produced or permitted the haze.—O. J. L.] Several instances of the action of clouds of dust were noted by Sergeant Morrill at Boston. On March 7, 1888, in the afternoon the potential was observed to fall rapidly from − 90 to − 270 upon the rising of an especially heavy cloud of dust, and similar phenomena were observed on April 7." "A fall of potential could be certainly predicted when a dust cloud was seen rising. On other days when high winds and dust clouds prevailed negative potential was observed. A figure is given of an observation at Terre Haute, Ind., on a day when a fog formed after sunset, and the potential then rapidly fell from + 1000 to − 200 volts." "The same phenomenon was frequently observed during the autumn when the formation of a haze or fog just as the sun was setting was a common occurrence."

---

[1] "Report of Studies of Atmospheric Electricity." By T. C. Mendenhall. Extract from Memoirs of the National Academy of Sciences, 1889. (Washington.)

The observer at Terre Haute (Sergeant McRae) wisely made special observations as to the possible effect of locomotives on a railway a quarter of a mile distant; but, so far as the recods show, the passage of a train, when not happening to coincide with a fog formation, did not seem to disturb the curves.

Clouds and Wind.

"The direct action of a cloud or group of clouds in producing a fall of potential was often observed." For instance the following at Boston: — "In the morning of January 3, 1888, the potential had been steadily positive. At 11.30 it was + 32 volts, from which it fell steadily at the approach toward the zenith of a small cumulus cloud, reaching − 21 volts. As the cloud passed away the potential rose to + 6, again falling to − 31 as a large mass of cumulus clouds approached. Later the sky became overcast, and the potential became steadily negative.

"On June 7, at 5.30 p.m., the potential fell from + 43 to − 173, and then rose slowly to its former value. The rise and fall occupied fifteen minutes, and coincided with the appearance over the buildings to the west of a fleecy cirro-stratus cloud and its disappearance over the institute building in which the electrometer was located.

"Again, on June 9 the potential was positive all day up to 5 p.m. At that hour it fell from + 73 to − 113, then rising to + 52. The sky was nearly free from clouds, and the fluctuation coincided with the approach and departure of a cirro-stratus cloud, passing about 15° from the zenith. The inductive action of the cloud was plainly suggested in all of these cases."

High wind also usually causes a drop of potential.

Averages.

Some charts are then given of average monthly potentials, showing nearly always positive average values, highest in the winter, lowest in summer.

Some smoothed diurnal curves are also given, and "seem to indicate the existence of two principal maxima of potential in the day, and also in a general way that one of these occurs not many hours before noon and the other toward the latter part of the day."

Thunderstorms.

Special attention was paid to the observations before, during, and after the occurrence of thunderstorms, but the needle then dashes wildly to either side, and sparks often begin to pass. And the remark is made :—"Aside from the general characteristics (rapidity and range of fluctuation) these potential curves seem to have little in common. The examination of a few cases only might lead to interesting conclusions, which would almost certainly be overthrown by the study of a greater number. Sometimes the potential falls rather steadily until the violent movements begin, but sometimes it rises just as long and steadily. In many cases the fluctuations start from a high positive, while in many others the reverse is the case. The storm is usually accompanied by precipitation; sometimes this begins before the needle starts on its series of swings from side to side, and sometimes these movements precede precipitation. The steady rise of potential for some hours immediately following a thunderstorm may mean that clear and fair weather is to be expected, but Fig. 71 is good evidence that it may also be interpreted to mean that another thunderstorm is just at hand."

"Although these records are somewhat unsatisfactory as far as throwing any light upon the nature of thunderstorms, it must not be forgotten that with a single exception [two stations at Washington] none of these storms have influenced more than one station. The complete investigation of a storm would demand a large number of observing stations relatively near to each other, by means of which a full history of the potential changes about and in all parts of the storm could be obtained.

"Such an examination might result in bringing order and system out of what seems at present little less than confusion."

Then follow many specimens of the actual photographic record at Baltimore on days when lightning occurred, and finally a mass of tables embodying abstracts of results at the different stations, and also some taken at Kew and Greenwich in England; though at both of these institutions the scale used appears to be arbitrary.

General Conclusions.

Among the conclusions the following may be noted: "Instruments similar in every respect, separated by a distance of a hundred meters may give very dissimilar indications." (Not merely, it is explained, as regards *absolute* values only, which may be expected to disagree, but as regards fluctuations also.) "Observers were instructed to study the appearance of negative electricity before and after and during precipitations, and at one time the hope was indulged in by the writer, as well as by several of the observers, that this phenomenon might afford great assistance in the prediction of local storms, rains, snows, &c., which offer so much difficulty in forecasting by present methods.

"Further observation and investigation, however, did not justify this expectation, serving rather to increase the meteorological conditions under which negative potential might be looked fcr, and to diminish the definition of relationship between it and precipitation. That negative electricity is tolerably certain to be observed in connection with precipitation in a majority of cases is doubtless true, but it does not appear in such a way as to be of any value in forecasting."

Near the end of the historical introduction we learn with regret that the observations thus tabulated and discussed are now no longer going on.

"In August, 1888, all observations were discontinued. It was thought that a sufficient number had been accumulated to decide the question of their use in weather forecasting, and in fact their study up to that date gave little encouragement in that direction." "Many questions of great scientific interest . . . had to be set aside for those likely to be of immediate practical value."

The amount of material thus rapidly accumulated, centralised, and well discussed, is typical of what can be done under efficient Government authorisation and by the head of a National Laboratory. The carrying on of the research for immediate utilitarian ends, and stopping it as soon as it was seen that the results aimed at were not forthcoming, is perhaps also typical.

It is to be hoped that some day the question will be reopened, and a fresh series of results obtained. So far as I (who am by no means a meteorologist) can judge, I should surmise that a number of fairly concentrated stations over a large plain would be desirable; and also that the vertical gradient of potential should be attempted by a series of collectors at different attitudes on a tall mast, or possibly up a hill-side.

Further, the general aspect of the curves seems to me to suggest that the instruments were almost too sensitive and not sufficiently dead-beat. They should be quick in indication and at the same time thoroughly damped, so that the record shall contain as little as possible of any effect due to instrumental inertia. Some very light quartz-fibre instrument might be devised, and perhaps it might contain its own recording apparatus in a compact form, so as to make registration a much easier and less cumbrous business than it has been hitherto.

When so much is unknown it is a mistake to begin by observing with too great intricacy of detail. The salient features should be first obtained, and then attention directed to the minutiæ; but one of the first things to do is to arrange that every swing in the curve shall mean a swing of atmospheric potential, and not a mere excursion of a heavy needle.

I hope that the energy, skill, and judgment of the various observers in the States, and of Mr. Mendenhall, the author of this valuable report, may be utilised through the resources of the U.S. Government by the inauguration of a fresh series of observations under somewhat different conditions, and without the hamper of any immediately specified practical object. OLIVER J. LODGE.

THE PRESERVATION OF THE NATIVE BIRDS OF NEW ZEALAND.

IN our issue of September 16 last year (vol. xlvi. p. 502) we printed an excellent memorandum drawn up by Lord Onslow, late Governor of New Zealand, relating to a proposal for the preservation of the native birds of that colony by setting apart two islands for this purpose, namely, Little Barrier or Hauturn Island in the north, and Resolution Island in the south. As regards the first of these islands, we have lately received a copy of the report by Mr. Henry Wright (addressed to the Hon. John Ballance, Premier of New Zealand) upon the subject. According to Mr. Wright, Hauturn Island, in the Gulf of Hauraki, which is almost circular in shape, and contains an area of from 9000 to 10,000 acres, rising in the middle to an elevation of about 2000 feet, is very well adapted for the purpose required. Writing with a thorough knowledge of all the north island, Mr. Wright is able to say that there is no other part of it where the native birds are to be found in anything like such profusion and variety. He gives a list of forty species to be met with within its limits, and mentions as particular varieties the stitch-bird or kotihe (*Pogonornis cincta*) and the large dark kiwi (*Apteryx bulleri*) as both found there. There are slight difficulties in the way of the project, such as the presence of about a dozen Maoris now living on the island, and of a claimant for the timber, which, in the shape of kauri pine (*Dammara australis*), is present in large quantities. There are no Weka Rails (*Ocydromus*) in the island to destroy the birds' eggs; and there are no bees, which, for some reasons, are considered to be highly inimical to the native birds in New Zealand. The wild pigs, formerly numerous, have been killed out; and the mutton-bird (*Œstrelata gouldi*), the young of which were formerly eaten by the pigs, will consequently be able to breed again undisturbed. Cats unfortunately are very numerous, but Mr. Wright proposes to offer at once a reward for their destruction, which is, of course, of great importance.

Mr. Wright's report seems quite convincing as to the suitability of Hauturn Island for the object in view, but we regret to hear that some difficulties have arisen in the Parliament of New Zealand as to the appropriation of the funds required for the purpose.

Lord Onslow, however, is not disposed to let the matter drop, and will, we are sure, be strongly supported by Lord Glasgow, the present Governor of New Zealand, in carrying the matter to a successful issue. The Council of the Zoological Society of London, whose attention has been called to the subject, have passed in its favour the following resolutions, which were communicated to a general meeting of that body on the 16th inst.

(1) The council of the Society have learnt with great satisfaction the steps that were proposed to be taken by the Earl of Onslow, when Governor of New Zealand, and by the Houses of General Assembly for the preservation of the native birds of New Zealand, by reserving certain small islands suitable for the purpose, and by affording the birds special protection on these islands.

(2) The council much regret to hear that difficulties have been encountered in carrying out this plan as regards one of these islands (Little Barrier Island), and trust that the Government of New Zealand may be induced to take the necessary steps to overcome these difficulties and to carry out this excellent scheme in its entirety.

(3) The council venture to suggest that besides the native birds to be protected in these reserves shelter should also be afforded to the remarkable Saurian, the Tuatera Lizard (*Sphenodon punctatus*), which is at present restricted to some small islands on the north coast of New Zealand, in the Bay of Plenty.

These resolutions have been communicated to the present Governor of New Zealand, and will, we trust, be of some assistance to him in inducing his Ministers to carry this excellent scheme into execution.

THE EARTHQUAKES IN ZANTE.

THE following is a list of the shocks of earthquake at Zante, compiled from telegrams published in the *Times* and *Standard*:—January 31, at daybreak, the most destructive earthquake, of which, however, some warning must have been given, if we may judge from the comparatively small loss of life. Other slighter shocks followed during the day. February 1, 2 a.m., another severe shock, felt also in Cephalonia. February 2, two more violent shocks, one of which caused some fresh damage. February 3, further shocks, but less frequent and violent. February 5, another violent shock. February 6, continued shocks of slight intensity, followed by three more severe ones in the afternoon and evening. February 7, another violent shock in the morning, resulting in but little additional damage. February 8, some slight shocks. February 10, some slight shocks in different districts. February 11, 1 a.m., a somewhat severe shock, followed by a succession of shocks between 8 and 9 p.m. February 12, further shocks in the early morning, soon after midnight, and again at intervals during the day. February 13 or 14, renewed slight shocks, accompanied by loud subterranean rumblings. The Athens correspondent of the *Times*, telegraphing on February 20, says: "The shocks of earthquake continue at Zante, with varying degrees of violence. No serious damage is reported, but those who are compelled to live in the half-ruined or insecure houses are exposed to frequent alarms." It is estimated that the total loss of property due to the shocks may exceed £600,000.

According to a telegram in the *Times* for February 6, the tide in Venice on the evening of February 1 "ebbed so low as to leave several of the canals without water. The gondola traffic was interrupted at different points, and many of those craft were stranded. This phenomenon corresponded with the earthquakes at Zante and Cephalonia." A simple calculation will show, however, that this can hardly have been due to the principal shock. The straight line joining Zante and Venice passes almost directly up the Adriatic, and its length is roughly 720 miles. Taking the time between daybreak on January 31 and the evening of Feb. 1 at 36 hours, this would give for the sea-wave an average velocity of 20 miles an hour, corresponding to an average depth of about 30 feet, which is considerably less than the actual amount, the mean depth of the Adriatic being 110 fathoms.

Earthquakes are frequent in Zante, and sometimes very severe. One of the most destructive shocks, which occurred on October 30, 1840, is described by Ansted in his work on the Ionian Islands (pp. 415-419) chiefly from the report of the Lord High Commissioner, Sir Howard Douglas. The prison was in this case also unroofed, and hardly a house in the town of Zante escaped some injury. All of the villages on, or bordering on, the plain suffered more or less, especially Sculikado, which was reduced to a heap of ruins. The total amount of damage done was estimated at not less than £300,000. The great earthquake was followed by a large number of others, some very severe, ninety-five being counted up to November 4. Ansted notes (pp. 368, 369) the curious fact that each of the Ionian Islands seems for the most part to have its own earthquakes, independently of the others. About the year 1818, he says, all the sensible shocks in Cephalonia and Zante were tabulated, the record extending over two and a quarter years. "During this time thirty distinct and well-marked shocks were recorded in Cephalonia; but in no case did the shocks in Zante, although nearly contemporaneous, absolutely coincide with them. In most cases an interval of some days, and almost always more than twenty-four hours, seems to have elapsed between the times of the disturbances in the two, although they are so near that in these days [1863] of long range, a cannon-shot fired from the one might reach to the other."

NOTES.

THE French Academy of Sciences has opened a subscription in support of the movement for the publication of the writings of Jean Servais Stas and the erection of a monument in his memory.

A MEETING of delegates of the Academies of Science at Berlin, Göttingen, Leipzig, Munich, and Vienna was held on January 29, under the presidency of Prof. Ribbeck. The object of the meeting was to prepare the way for a sort of federal union of the various German scientific societies, so that they may be able to act together about important matters of common interest. A hope was expressed that a great international confederation of scientific societies might ultimately be formed.

ANNOUNCEMENT has been made of the death, on February 2, 1893, at Hendaye, in the Department of the Basses Pyrénées, in his sixty-eighth year, of M. Victor Aimé Léon Olphe-Galliard, author, among other works, of "Contributions à la Faune Ornithologique de l'Europe Occidentale," in forty livraisons (of which the last was published in 1892) giving an elaborate description of the birds not merely of Western but of almost the whole of Europe, to say nothing of allied species belonging to other countries. M. Olphe-Galliard (whose name few writers, even Frenchmen, spell correctly) was remarkable among his countrymen for his knowledge of other languages than his own, and his recognition of the works of foreign ornithologists stands out in great contrast with that accorded to them by most continental authors. He translated into French several valuable papers written in Swedish and other tongues as little known, thus bringing them before readers to whom they would have been otherwise inaccessible, while he still further showed his appreciation of foreign naturalists by introducing into his principal work portraits of Johann Friedrich Naumann and William Macgillivray as the representative ornithologists of Germany and Great Britain. The earliest performance by which M. Olphe-Galliard will be remembered was his description in the *Annales* of the National Society of Lyons for 1852 of the interesting Algerian bird which he called *Erithacus Moussieri*, after a French army-surgeon of that name who had recognised it as a new species in 1846. In the following year specimens of it were procured by the late Mr. Louis Fraser, and placed in the British Museum, but they met no kind reception there then, or even later, for the species finds itself in the *Catalogue of Birds* (vii. p. 20) far removed from what all naturalists who have observed it in life declare to be its nearest relations—the Stonechats or the Redstarts—and shot into the rubbish-hole placarded *Timeliidæ*, where no one would ever think of looking for it. M. Olphe-Galliard's latest publication consisted of letters addressed to him by the somewhat eccentric Christian Ludwig Brehm, which appeared in the *Ornithologisches Jahrbuch* for 1892.

A MEETING of conchologists is to be held at 67, Chancery Lane, on Monday, February 27, at 8 p.m., for the purpose of founding a "Malacological Society of London."

THE Geologists' Association has arranged for a visit of the members to the British Museum (Natural History), Cromwell Road, on March 18, when Mr. W. Carruthers will give a demonstration on "Gymnosperms from the Devonian to the present time." There will be an excursion to Norwich, Cromer, and Lowestoft at Easter.

SOME admirable suggestions for the guidance of teachers of evening classes in wood-working under the direction of County Councils have been prepared by the Examination Board and Committee of the City and Guilds of London Institute. The suggestions relate to drawing lessons, object lessons, and bench-work lessons.

THE type of weather during the past week has undergone but little change from that of the preceding week. Anticyclonic areas lay over Scandinavia and Spain, and low pressure systems continued to skirt our north and west coasts. The general conditions, however, were much quieter, although a deep depression reached the west of Ireland on Sunday, causing gales on our western coasts. On Tuesday a large and important disturbance arrived over the south-west of England from off the Atlantic, and the wind circulation around its central area was complete. The difference of barometric pressure was, however, by no means large in different parts of the kingdom, and consequently there was not much wind. The barometer fell as low as 28·7 inches over the centre of the cyclonic area, and later during the day the disturbance continued its passage across England, and was accompanied by heavy rain. Temperature continued high for the season, the daily maxima ranging generally from 45° to 55°, while on Sunday, the 19th inst., the thermometer rose to 60° in the inland parts of England. In London it reached 59°, which was a higher reading than had been recorded so early in the year since 1878. The sky was exceptionally brilliant in the east and south-east on that day, but on the whole the air has been very damp throughout the week, and rainfall has been of almost daily occurrence. For the week ended the 18th inst. the rainfall exceeded the mean in all districts, except in the east of England. In the west of Scotland and the south-west of England the excess was considerable. Bright sunshine only exceeded the normal amount in Ireland and the north and east of Scotland.

THE Pilot Chart of the North Atlantic Ocean for February, 1893, shows that the weather in the North Atlantic during January was not abnormally severe, and that the eastern part of the ocean was unusually free from storms. A map is given illustrating the great size and severity of the hurricane of December 22 last, which had moved rapidly from Hatteras in an east-north-east direction. At the time selected for illustration, when the centre lay in longitude 36° west, the storm area covered the entire Atlantic from Labrador and Nova Scotia to Madeira, Portugal, and Ireland. Some very low barometer readings were recorded, the lowest being 27·75 inches. There was a large amount of ice during January along the coast of

America, as far south as Hatteras; in Chesapeake Bay it was reported to be thicker than for twenty-five years.

THE official report of the International Meteorological Conference at Munich from August 26 to September 2, 1891, has now been issued. It contains protocols of the various meetings, with appendices and supplements.

THESSALY was supposed to have got rid of the plague of field mice, but it appears that the congratulations offered to her were somewhat premature. The Athens correspondent of the *Times* telegraphs that swarms of these troublesome creatures are beginning to reappear both in Thessaly and in the neighbouring district of Phthiotis. "It was hoped," he says, "that the severe cold and heavy rains of the last few months had exterminated them, but they seem to have taken refuge in the mountains, and are now returning in large numbers to the plains. The Prefect of Phthiotis has applied to the Government for instructions as to the best means of dealing with this destructive pests."

ACCORDING to a correspondent of the *Scotsman*, writing from Borthwickbrae, Selkirkshire, the mice pest in Scotland has greatly diminished, if it has not entirely disappeared, during the last two months. "The great abundance of owls," he says, "coupled with the very severe weather, has no doubt given them a check." During the severe storm of last month the owls, unfortunately, suffered also. The keeper at Alemoor Loch counted over thirty of the short-eared or heather owl, and eight kestrel hawks—some lying dead, others able to fly a few yards only, while several sat until lifted in the hands. The short-eared owls did not go to the woods to roost, which were close to the loch, but were in the willows and reeds along the edge of the loch.

SIR EDWARD BIRKBECK has accepted the presidency of the British Sea-Anglers' Society, which was founded recently at a meeting held in London. It is proposed that the Society shall have branches in all parts of the United Kingdom, and the members hope that they may be able not only to secure for themselves certain advantages in connection with their favourite sport, but to be of some public service. The chairman of the preliminary meeting, Mr. C. H. Cook, touched on the question of legislation for the protection of sea-fish. "I hope," he said, "that the anglers will take up the cause of immature sea-fish. Already a movement, to which we may give a strong impetus, is rolling forward in this direction, but it is checked by the trawlers' interests. The harm done by these men is almost incalculable. I have seen their nets within a stone's throw of the shore, in less than three fathoms of water, where they scoop up and destroy the infant fish by the million. It may be that the evidence tendered by trustworthy members of the Sea-Anglers' Society may be the means of putting an end to inshore trawling. I hope it will. It often happens that the information given to the Fishery Boards is wilfully misleading, owing to it being given by fishermen, who fear they will lose their living."

THE Council of the Cremation Society of England, in its Report for 1892, expresses much satisfaction with the progress made by the cause which the Society represents. It seems that within the year no fewer than 104 bodies were cremated, "including a large proportion of individuals well known in society by their connection with art, science, or literature, or by a distinguished position of some other kind, ten having been members of the medical profession."

MR. A. H. S. LUCAS, who has edited the *Victorian Naturalist* admirably since it was started nearly nine years ago, has tendered his resignation in consequence of his election to the head-mastership of Newington College, Sydney. The Field Naturalists' Club, of Victoria, to which the magazine belongs, has expressed its cordial thanks to Mr. Lucas for his services. Mr. F. G. A. Barnard, who has been both secretary and librarian of the club, will act for the present as Mr. Lucas's successor.

A MOST interesting and suggestive paper on "pottery glazes: their classification and decorative value in ceramic design" was read by Mr. W. P. Rix at the meeting of the Society of Arts on February 7. It is printed in the current number of the Society's Journal. Mr. Rix tries to show that the relative merit of various glazes is based upon certain optical principles, which have only been partially examined by men of science, and that these principles, underlying the pleasurable sensations to the eye, really govern that which we are pleased to call good taste and excellence, so far as glazes are concerned, and are not mere matters of opinion. The reading of the paper was followed by a lively discussion, in the course of which Mr. Binns quoted a saying attributed to Mr. Gladstone, that a fine piece of glaze "feels like the touch of a baby's hand." Mr. Binns had often been struck with the aptness of the illustration. There was a peculiar soft texture in a fine piece of glaze that only a connoisseur could appreciate.

THE *Times* of Tuesday gives an account of a process by which anthracite coal bricks are now being manufactured. The bricks are made of grains of anthracite dust, which are forced to cohere by means of a special cementing compound and by great pressure. The coal dust is mixed with the binding material in the proportion of 96 per cent. of the former to 4 per cent. of the latter. The compound is fed into a mixer, where it meets a jet of steam, a stiff paste being formed, which is delivered successively into a series of moulds under a pressure of 25 cwt. As the mould plate revolves, the charge in each mould is brought between two rams, which exert a pressure of two tons per square inch on each side of the charge, forming a very dense and homogeneous coal brick. The brick, still in the mould, passes on to the delivery ram, by which it is pushed out on to a table, and is removed for the market. These coal bricks are said to make an excellent fuel and to possess a very high efficiency for steam-raising purposes. The *Times* thinks that with such a fuel at the disposal of the public there is room to hope for a reduction in the pollution of the atmosphere of towns, as well as a reduction in the coal bills of steamship companies and of steam users generally. It adds that the invention is being worked by the Coal Brick Syndicate, of 2, Trafalgar-buildings, Northumberland Avenue, London.

IT seems that serious depredations have been committed among the recently-discovered Phœnician tombs at Gebel Imtarfa, in Malta. The *Mediterranean Naturalist* says that the manner in which not only these tombs, but many others, have been rifled of their contents by irresponsible curiosity hunters, and the state in which many of the ancient ruins of the islands now are constitute a disgrace to European archæological science. More has been done to obliterate and destroy vestiges of Malta's ancient history during the last two centuries than was effected in the preceding two thousand years. Orders have been issued from head-quarters, Valletta, to the effect that the District Commanding Royal Engineer is to report immediately any discoveries of ancient tombs, burial places, or pottery that may occur in course of excavations for works, or come to light in any way; and that such objects are to be carefully preserved until they have been inspected by an officer of the Civil Government, and left untouched *in situ* until this inspection has been made.

A DISCUSSION on Mr. E. G. Carey's paper—to which we lately referred—on the bridges of the Manchester Ship Canal is reported in the new instalment of the Transactions of the Institution of Engineers and Shipbuilders in Scotland. Mr. Carey, in the course of his reply to the various speakers, alluded to the question as to the value of annealing steel. He said that, so far as his experience went, annealing steel certainly removed all stress. At the Forth Bridge they were very curious about this subject. They had a single strip of steel, which they strained up to some 30 times, to about 25 tons on the square inch. After every straining, it was annealed. That went on for days and weeks, and the steel seemed to be literally the same as when they started. The experiment grew wearisome, and ultimately, when the strain was run up inadvertently to about 30 tons per square inch, and the specimen finally broke, it was almost a relief, but it proved that the annealing of steel removed all strain, and that, although injured, if annealed, it seemed to recover its former properties.

A VALUABLE synonymic and bibliographical catalogue of the New Zealand land and freshwater Mollusca, by H. Suter, was communicated to the Linnean Society of New South Wales at its meeting on December 28. In 1880 Prof. Hutton, in his "Manual of the New Zealand Mollusca," enumerated 125 species of land, fresh, and brackish water molluscs. Since then zoology has made such rapid strides that this fauna is raised in Mr. Suter's catalogue to a total of 178 species, divided by him into 45 genera. The land mollusca embrace 142 species, of which 15 are operculate; the fluviatile shells are reckoned at 32, 12 being bivalves and 7 operculate univalves. This large addition of one-third to the list of twelve years ago is not the greatest advantage the present catalogue has over its predecessor; numerous species are now removed which, by the negligence of collectors or the errors of European authors, were formerly included among the shells of New Zealand. The attention bestowed during the last decade upon the anatomy of the New Zealand snails has furnished data for a more natural classification, while the increase of colonial libraries has facilitated the quotation of fuller references than were previously available.

MR. J. M. STAHL, Illinois, has much to say in the *American Agriculturist* about the virtues of wood ashes. Speaking of them as a medicine for farm animals, he says he has found them of great value. He has raised swine rather extensively for more than twenty years without cholera or swine plague, and has not lost one per cent. of his hogs from disease. He keeps wood ashes, and charcoal mixed with salt, constantly before his swine in a large covered box with holes two-by-six inches near the bottom. The hogs will work the mixture out through these holes as fast as they want it. He selects ashes rich in charcoal, and mixes three parts of ashes to one of salt. There is no danger of the swine eating too much of this mixture, or of pure salt, if it is kept constantly before them, and they are provided with water. The beneficial effects of the mixture are quite marked, especially when the hogs are fattened on fresh maize. A little wood ashes, given to horses, is also, he maintains, very beneficial. In thirty-seven years' experience upon the farm he has lost but one horse, and this was overheated in the horse-power of a threshing-machine during his absence, and the only "condition powder" he has ever used has been clean wood ashes. The ashes may be given by putting an even teaspoonful on the oats twice a week, but he prefers to keep the ashes and salt mixture constantly before the horses, and has made for it a little compartment in one corner of the feed box. His experience is that the best condition powder is a mixture of three parts wood ashes to one of salt; and that when it is given regularly, and reasonable care and intelligence are used in handling the horse, no other medicines are necessary. Mr. Stahl has also great faith in the efficacy of wood ashes as a fertiliser.

A VALUABLE paper on the industrial resources of the Caucasus, by an Austrian official, Herr G. Sedlaczek, is summarised in the Board of Trade Journal for February. Dealing with the silk industry, the author says that the Russian Government has spent more money for the furtherance of this department of trade than for any other industrial purpose in Caucasia, and that the results are in no way commensurate with the trouble and outlay. Although the country possesses innumerable mulberry trees, in some parts forming veritable forests, and excellently suited for feeding silkworms, although the climatic conditions are favourable, and the inhabitants have from time immemorial been familiar with the working up of the raw material, the most untiring efforts of the Government have proved little else than a struggle to preserve the mere existence of the silk culture and industry. The estimated production of silk in Transcaucasia at the present day is 36,000 pouds, although in 1855 it was 30,000 pouds. The average value of the produce is said to be about 6,000,000 roubles. Considerable advance has been made in reeling, spinning, and twisting; new foreign machinery is everywhere at work, and all that is wanting is a good raw material, the production of which is, however, being constantly prevented, on the one hand by disease in the worms, and on the other by the indolence of the producers. The Russian demand for silk is far from covered by native production, silk being annually imported to the value of about 12½ millions of roubles, while the exports amount only to about 3,000,000 roubles in value. In spite of protective duties the imports are increasing while the exports are decreasing.

MANY marine animals (radiolaria, ctenophora, &c.) rise and sink slowly in the water, having some means, apparently, of changing their specific gravity. This has been recently studied by Herr Verworn (*Pflüger's Archiv*), in the case of *Thalassicolla nucleata*, a radiolarian about the size of a pea. It has a central capsule with nucleus, a coarse endoplasm, a vacuole-layer, a gelatinous-layer, and ray-like processes. As a rule, these animals float at the surface. They sink on seizing food heavier than themselves, also when strongly stimulated by shaking, or by chemical agents. It was found that the central capsule and the gelatinous layer are both heavier than sea-water, while the vacuole-layer is lighter. On being stimulated, the pseudopodia (or processes) were drawn into the vacuole-layer, and the protoplasm also retired from this, the walls of the vacuoles flattening from without inwards, till at length very little of them was left. Then the animal began to sink. At the bottom the vacuoles were soon regenerated, and the animal rose again. Thus it appears that the vacuole-layer is the hydrostatic apparatus of these organisms, the vacuole liquid being that part of the cell which is lighter than sea-water, and keeps the cell at the surface. The same probably holds good with other pelagic animals. That the vacuole-liquid is lighter than the sea-water from which it comes is no difficulty, since it is known that living protoplasm is impermeable for many salts.

A VOLUMETRIC method for determining the amount of chromium in a specimen of steel has become a great metallurgical desideratum since the good qualities conferred upon steel by its addition have become generally known. Such a method is described by G. Giorgis, of the University of Rome, in the *Atti* of the *Accademia dei Lincei*. It is founded upon the formation of potassium chromate and hydrated manganese sesquioxide on adding a solution of potassium permanganate to a solution of sesquioxide of chromium in potassium hydrate. Ten grammes of the steel are dissolved in a mixture of sulphuric and nitric acids (3 to 1), the solution is made up to 1 litre with distilled water, and 250 c.c. are made just alkaline with sodium hydrate, and treated with hot permanganate of potash till the solution assumes a red colour. After cooling the whole is poured into a flask of 500 c.c. capacity, filling up with water. 400 c.c. are filtered through a dry filter, acidified with sulphuric acid, reduced by SO_2, and concentrated to 200 or 100 c.c., according to the quantity of chromium probably present. Donath's method may then be employed, consisting in the addition of the chromium salt prepared as above described, to a measured quantity of a standard permanganate solution, and watching for the golden yellow colour assumed by the mixture when the permanganate is all dissolved, *i.e.* when all the chromium exists in the form of a chromate, from which the amount of chromium is easily calculated. It is said that this process is extremely accurate, and requires only a small fraction of the time required by gravimetric methods.

The subject of dew appears to be still involved in some controversy. An experimental contribution to it has been recently made by Herr Wollny (*Forschungen*, &c.), who used plants in glazed pots with earth of varying moisture, some of these being allowed to radiate freely on favourable nights, while others were screened. The following is a brief outline of Herr Wollny's views:—Dew depends partly on evaporation from the ground, partly on transpiration. It is at present doubtful whether precipitates from the air share in it or not. A cloudy sky weakens the cooling process without stopping it wholly. With copious radiation, the temperature minimum is at the surface of the plant-covering (of the ground), and here the aqueous vapour rising from the warm ground is partly precipitated. With increase of the ground-heat downward there is increase of the water brought up by the plants, which is given up as vapour and condensed. The more moisture there is in the ground, the more water is evaporated from the ground and the plants. Dew formation is usually favoured by the larger number of stomata on the under surface of leaves than on the upper. On a given surface of ground the dew is more plentiful the stronger the plant organs above ground, and the closer the plant growth. The temperature of still air increases from the surface to a certain limit (at about 5 feet over grass it was sometimes 4° or 5° C. warmer than on the ground). In experiments with blotting paper, cotton wool, feathers, and asbestos, the first was much moistened, while the others showed dew in drops. Bodies of organic origin attract more moisture than those of mineral (a case of hygroscopic absorption). For vegetation, the author considers the benefit of dew but trifling. Of the whole annual precipitation at Munich dew only gave 3·23 per cent.

With the present year the weekly *Botanische Zeitung* enters on the fifty-first year of its existence, and Graf zu Solms-Laubach gives with the first number of the year an interesting sketch of its history, uninterrupted for half a century, even during the stormy period of 1847–1849. The inception of the undertaking was due to the suggestion of a botanist still living, Dr. Carl Müller, of Halle. The first number of the *Botanische Zeitung* appeared on January 9, 1843, under the editorship of Von Mohl and Schlechtendal. The editorial chair has been occupied since then by some of the most distinguished German botanists, De Bary, Hallier, Kraus, Jost, and the present editors, Solms-Laubach and Wortmann.

Dr. Vines, the Professor of Botany in the University of Oxford, has for some time past had in preparation a "Student's Text-book of Botany," which will be more comprehensive than his edition of Prantl's well-known "Elementary Text-book." It is to be fully illustrated, and is expected to be ready early in the autumn of this year. It will be published by Messrs. Swan Sonnenschein and Co.

Messrs. Gauthier-Villars et Fils, Paris, continue to issue the useful series of small volumes called "Encyclopédie Scientifique des Aide-Mémoire." The following volumes have lately been added: "Corderie," by M. Alheilig; "Formation des Gîtes Métallifères," by L. de Launay; "Le Grisou," by M. Le Chatelier; "Moteurs à Vapeur," by M. Dudebout; "Détente Variable de la Vapeur," by A. Madamet; "Canons, Torpilles, et Cuirasses," by A. Croneau; "Textiles Végétaux," by H. Lecomte; "Essais d'Or et d'Argent," by H. Gautier; "État Actuel de la Marine de Guerre," by L. E. Bertin; "Industrie des Cuirs et des Peaux," by Ferdinand Jean.

The "Annuaire," for 1893, of the Royal Observatory of Belgium, by F. Folie, has been published. This is the sixtieth year of issue.

The Department of Science and Art has issued the volume for 1893 containing its calendar, history, and general summary of regulations.

In the course of an elaborate investigation recently published in the *Zeitschrift für Hygiene*, December 9, 1892 ("Die Aetiologie des infectiösen fieberhaften Icterus" (Weil'sche Krankheit), Jaeger draws attention to the dangers which may arise from bathing in polluted water. Already in 1888 Pfuhl (*Deutsche militär-ärztl. Zeitschrift*, 1888, Heft 9 and 10) attributed an outbreak of typhoid fever, accompanied by jaundice, which occurred amongst the garrison stationed at Altona to bathing in the Elbe, which at the time was described as more than usually polluted. Hüeber and Globig came to similar conclusions with regard to outbreaks of the above "Weil'sche Krankheit," which appeared at Ulm on the Danube and Lehe respectively. Jaeger has made a special study of the cases which arose amongst the soldiers at Ulm, and has endeavoured to trace, if possible, the infection to its source. It was found that the military bathing-place was situated below the point where the Danube is joined by the highly-polluted river Blau. This stream is described as being practically an open sewer, and even before it reaches Ulm is stated to be grossly contaminated in its flow through the small village of Söflingen. It was further ascertained that in this village for many years a mysterious disease had been rife amongst the ducks and geese, whilst fowls were also occasionally attacked, and that moreover it was a common custom to throw the dead carcases of these animals into the Blau as the readiest means of getting rid of them. A careful examination of some of the birds which had succumbed to this disease revealed the constant presence of a micro-organism, which Jaeger asserts was identical with that found repeatedly and isolated in the cases of icterus investigated by him at Ulm. It is further stated that by mixing some of the highly-polluted Blau water at Söflingen with sterile broth, and inoculating it into white mice, they were killed in sixteen hours, and that the organism, which was found abundantly present in various organs of the body, was in every respect identical with that previously isolated in the cases of icterus at Ulm, and from the carcases of the birds at Söflingen. Taking these various results into consideration Jaeger is of opinion that they afford very strong evidence of the virus of this disease having been introduced into the highly contaminated stream at Söflingen, and conveyed thence to the military bathing-place, which, as already mentioned, is situated below the junction of the Blau with the Danube. In consequence of the appearances in cultivations to which this organism gives rise, the author has suggested for its name *Bacillus proteus fluorescens*, and claims in it to have discovered the exciting cause of the so-called "Weil'sche Krankheit," the etiology of which is attracting much attention on the continent.

Notes from the Marine Biological Station, Plymouth:—Heavy gales have prevailed for many weeks, confining operations to the inshore waters. The week's captures include numbers of the Archiannelid *Dinophilus tæniatus*, of the Polychæta *Marphysa* *sanguinea* and *Sigalion boa*, and of the Nudibranch *Ancula cristata*. In addition to the forms mentioned last week, the townettings have contained the Siphonophore *Muggiæa atlantica*, the Anthomedusa *Margellium* (*Lizzia*) *octopunctatum*, and several ephyræ of *Aurelia*, together with numbers of Teleostean ova, Prosobranch and Opisthobranch veligers, larval Lamellibranchs and *Cyphonautes*-larvæ. The Polychæte *Cirratulus cirratus* and Gastropod *Littorina littoralis* are also breeding.

THE additions to the Zoological Society's Gardens during the past week include a Vervet Monkey (*Cercopithecus lalandii*) from South Africa, presented by Mr. Walter Neall; two Red and Yellow Macaws (*Ara chloroptera*) from South America, presented by Mr. Henry Goschen; a Herring Gull (*Larus argentatus*) European, presented by Mr. W. R. Galbraith; a Bar-breasted Finch (*Munia nisoria*) from Java, presented by Mr. Sydney D. Birch; two Whooper Swans (*Cygnus musicus*) European, purchased; a Vulpine Phalanger (*Phalangista vulpina*), three Barbary Mice (*Mus barbarus*) born in the Gardens.

OUR ASTRONOMICAL COLUMN.

COMET BROOKS (NOVEMBER 19, 1892).—The following ephemeris for Comet Brooks is taken from *Astronomische Nachrichten*, No. 3142:—

1893.		R.A. (app.)		Decl. (app.)
		h. m. s.		° ′
Feb. 23	...	0 31 49	...	+24 18·2
24	...	33 0	...	23 59·8
25	...	34 9	...	23 42·1
26	...	35 17	...	23 25·0
27	...	36 24	...	23 8·5
28	...	37 30	...	22 52·4
March 1	...	0 38 34	...	22 36·8

COMET HOLMES (1892 III.).—Several communications with respect to the late appearances of this comet are inserted in the Comet Notes of *Astronomy and Astrophysics* for February, among which will be found one by Prof. E. Barnard. Observing with a 12-inch on the night of January 16, at 8h. 10m., he found that an estimation of the comet's diameter gave 30″, while a setting of the wires indicated 29″·4. While under observation "*the comet seemed to be perceptibly brightening*," and further measurements at 9h. 45m. gave a diameter of 32″·4. At this time he says: "The nucleus had developed clearly, and was very noticeable as a small, ill-defined star." With the 36-inch, which he was able to use later, he made the following measures, which we reproduce here, as they are quite unique in showing the increase in diameter of a comet due evidently to some external impact:—

Standard Pacific time.					Diameter.
h. m.					″
10 29	...	...	...	...	43·4
10 30	...	...	...	...	44·9
10 31	...	...	...	...	43·6
10 42	...	...	...	...	47·8
10 43	...	...	...	...	47·9
10 45	...	...	...	...	46·0
11 13	...	...	...	...	47·3
11 15	...	...	...	...	46·1

In concluding his remarks he says: "This is certainly the most remarkable comet I have ever seen, taking everything into consideration."

The following is the ephemeris for this week:—

Greenwich, Midnight.

SOLAR OBSERVATIONS AT ROME.—In the *Memorie Degli Spettroscopisti Italiani* for January, Prof. Tacchini communicates the observations made at the Royal College with respect to the various phenomena observed at the solar surface during the third trimestre of 1892. Dealing first with the prominences the total number for each of the months are respectively for north latitudes, 182, 129, 120, total 431; and for south latitudes 141, 167, 185, the total number here amounting to 493. The balance here is in favour of the southern hemisphere for greater frequency, but a curious fact may here be remarked, and that is that the maxima for the north and south latitudes occur in the months of July and September respectively, each exceeding considerably the number of prominences recorded for the same month in the opposite hemisphere.

The greatest frequencies occurred in latitudes (+60° + 70°) and (−50° − 60°). The groups of spots seem to have predominated slightly in the southern latitudes, the record showing 49 against 41; at the equator as many as 13 for zone (0° + 10°) were seen, the zone (0° − 10°) showing only 4; the relative frequency occurred here in the same zones in both hemispheres (±10° ± 20°).

With reference to eruptions, the month of July contains the only records, six for the northern, and three for the southern hemisphere, four of these taking place in zone (+10° + 20°).

Prof. Tacchini also has a note on the great prominence of November 16 last, in which he describes in detail the numerous observations which he was fortunate to procure. Although one can gather a good idea of the rapidity of the ascent from the table, the figures which accompany it show in a striking manner the great changes of shape that was such a conspicuous feature in its ascent. At 9h. 0m. on the 16th the height was only 131″·8, but at 1h. it had reached 319″·2, and at 1h. 35m., 534″·3, this being its maximum height. It is interesting to notice the numbers showing the increase of altitude in *one* minute of time.

For instance, at 11h. 55m. the increase of altitude per minute was 0″·56, at 1h. 4m. it was 6″·75, decreasing from this value to 4″·34 at 1h. 27m. At 1h. 32m. the velocity of ascent was increased, the value amounting to 9″·72, but at 1h. 34m. the increase of altitude reached its maximum, 20″·80, showing the ascent per minute.

THE STAR CATALOGUE OF THE "ASTRONOMISCHE GESSELSCHAFT."—The Harvard College Observatory has now completed the task of cataloguing the zone of stars undertaken in connection with the great catalogue of the *Astronomische Gesselschaft*. The stars included number 8627, and lie between 49° 50′ and 55° 10′ north declination, and the positions are reduced to the epoch 1875. Most of the observations were made by Prof. Rogers during the years 1870–1884, and the reductions have throughout been in his charge. The publication appears simultaneously as vol. xv. part ii. of the *Annals of the Harvard Observatory*, and as one of the volumes of the *Gesselschaft*. All concerned are to be congratulated on the completion of the zone, which involved over twenty-six thousand observations and an immense amount of calculation.

NOVA AURIGÆ.—Mr. Fowler draws attention to the fact that the nova is still as bright as ninth magnitude, and therefore easily visible in comparatively small telescopes. Its spectrum seems to consist of the two bright nebula lines near wave-lengths 5006 and 4956. The latter is only slightly fainter than that at 5006.

PARALLAX OF β CYGNI.—Mr. Harold Jacoby, whose work on the reduction of the Rutherford photographic measures of the stars about β Cygni we have previously referred to, suggests in *Astronomical Journal*, No. 287, that the discrepancies in the results can be explained on the hypothesis of a parallax of β Cygni amounting nearly to a whole second of arc. To investigate this he has chosen five pairs of comparison stars, from which he has computed the parallax from each pair separately by "using the difference of the distances of the two comparison stars from β as the quantity from whose variation the parallax should appear;" in this way he has obtained the weighted mean for the parallax to be + 0″·97, a value which, if endorsed by further observations will show us that of all stars β Cygni is one of our nearest neighbours.

GEOGRAPHICAL NOTES.

MR. G. B. GRUNDY, of Brasenose College, the student in geography appointed jointly by the University of Oxford and the Royal Geographical Society, has made a careful survey of the battlefield and site of the town of Platæa and of Leuctra, in Greece. He is now engaged in preparing a comprehensive memoir on the subject which may be expected to throw new light on some questions of historical geography.

MR. MACKINDER, in his fifth lecture for the Royal Geographical Society's education scheme, spoke of the chief lines of communication between Asia and Europe and the ways by which successive bands or hordes of Asiatic invaders forced a passage into the heart of Europe. The routes across Asia Minor from the Gate of Cilicia to the northern waters, and the thoroughfare through the Balkan peninsula now traversed by the international railway, were shown to have guided the movements of peoples and the formation or dissolution of nations from the dawn of European history on to the present day.

THE United States appears to have entered the field as an aggrandising power, taking up territory beyond the limits of the continent of North America. The annexation of Hawaii seems likely to be effected without remonstrance, and a footing has also been obtained in San Domingo, the eastern part of the island of Haiti.

MR. A. VAUGHAN WILLIAMS has been exploring the region round the mouth of the Sabi River in south-east Africa. He has ascended the stream for thirty miles to the limit of tidal influence.

THE orthography of African place names is a perpetual source of confusion. It appears that in place of Zimbabwe or Zimbabye we ought, in order to render the sound of the word used by the people surrounding the ruins, to write "Zimbabghi." The familiar name Mashonaland is in itself a corruption of the native name, but is always pronounced Mashunaland, a pronunciation to which the spelling ought to conform.

RAILWAYS seem likely at last to become established in China. The line from Teintsin to Taku has now been extended to the River Lan, a total distance of 130 miles, and is being rapidly pushed northward, a considerable section being already opened for passenger traffic.

CAPTAIN BOWER'S JOURNEY IN TIBET.

AT an extra meeting of the Royal Geographical Society, on Monday night, Captain H. Bower described his recent journey with Dr. Thorold across Tibet from west to east. They set out from Leh on June 14, 1891, and were fortunate enough to get well into Tibet before meeting any natives. Travelling due east they crossed a pass of 18,400 feet, on the other side of which lay the Horpa Cho, the highest lake yet met with in Tibet, and probably the highest in the world, its altitude being 17,930 feet. Along the route eastward many other lakes were passed, all salt and without outlet, the want of fresh water being sometimes severely felt; a kettleful of hailstones was a welcome catch on one occasion. The travellers used ponies and donkeys for carrying their loads, as yaks do not eat grain, and grass was often not met with for many days' journey. At length, after travelling east and south-east for about 700 miles, they were stopped within 200 miles of Lhasa by the Tibetans, who paid no attention to Chinese passports, and after much parleying insisted on a complete change of route. The party had to retrace their steps for several days' march, turn northward, and then make their way east at a safer distance from the capital. It was now the month of October and the crossing of passes over 18,000 feet, with temperatures of 15° or more below zero, in strong wind was extremely trying. About the end of November, for the first time for four months, the tents were pitched at a less altitude than 15,000 feet, and soon afterwards Chiamdo was reached. Here great difficulty was experienced with the lamas, who insisted that no European should enter the town; but by the intervention of the Chinese Amban, whose power was really but slight, the party was allowed to proceed, passing round the outside of the town. From Chiamdo to Batang the way was easy, and no difficulties were experienced thereafter. At Ta-Chen-Lu they entered China and reached Shanghai on March 29, 1892. Throughout Central Tibet the authorities disclaimed the sovereignty of China, maintaining that only the grand lama had jurisdiction in that region. Many of the lamas met with were educated and intelligent men, but not inclined to give information. Much difficulty was experienced in getting the names of lakes and mountains, no two Tibetans giving the same answer. The fanaticism and distrust of the people created constant difficulties, but Captain Bower, under the pretext of being a Buddhist with a peculiar ritual, succeeded in making observations for position openly as part of a religious service, previous attempts to do so by stealth having failed.

THE CHEMISTRY OF OSMIUM.

AN important addition to our knowledge of the chemical nature of this interesting element is contributed by Prof. Moraht and Dr. Wischin, of Munich, to the current number of the *Zeitschrift für Anorganische Chemie*. Two years have scarcely elapsed since the position of osmium in the periodic system was finally decided by the painstaking re-determination of its atomic weight by Prof. Seubert. Previous determinations of the atomic weight of osmium had been made with material which Seubert subsequently showed to be impure, and in consequence the erroneous value, 198·6, had been ascribed to it. Indeed previous to the year 1878 the order of precedence as regards atomic weight of the four metals of the platinum group —gold 196·2, iridium 196·7, platinum 196·7, and osmium 198·6 —was entirely at variance with the order demanded by their chemical and physical properties, and a standing contradiction of the periodic law of Newlands and Mendeleef. In that year, however, Seubert attacked the case of iridium, and as the result of a series of determinations, made with the laborious care which has characterised all his work, the atomic weight of this metal, when obtained in a pure state, was shown to be 192·5, a number very different to that previously assigned to it, and which was afterwards remarkably confirmed, even to the decimal place, by an independent investigation by Joly. Three years later Seubert made his celebrated re-determination of the atomic weight of platinum, which resulted in the number 194·3 being finally derived for the true atomic weight of the perfectly pure metal. This value was likewise subsequently confirmed by Halberstadt. In the year 1887 the position of gold was decided by simultaneous independent re-determinations of its atomic weight by Thorpe and Laurie in this country and Krüss in Germany, the two values being practically identical, 196·7. Lastly, in 1891, Seubert completed his work by re-determining the atomic weight of osmium with a specimen of the metal of practically perfect purity, with the result that the old number, 198·6, was found to be entirely erroneous, due to considerable quantities of impurities being present in the samples previously employed, and that the real value of this constant was 190·3, thus removing osmium from its former situation at the end of the series and placing it in its proper position at the head of it.

The order of precedence of the metals of the platinum group is therefore as follows:—Osmium 190·3, iridium 192·5, platinum 194·3, and gold 196·7. This order is in full accordance with the relative chemical and physical properties of these metals, and the last outstanding exception to the periodic generalisation has disappeared.

Although the properties of pure metallic osmium, and particularly its atomic weight, are now known with certainty, the nature of its compounds is yet very little understood. Moreover, it is evident from the result of the investigation of Prof. Seubert that previous workers have been dealing with an impure metal of atomic weight, 198·6. It was therefore desirable that not only should the chemistry of this element be extended to compounds hitherto uninvestigated, but that the composition and properties of the compounds already known should be subjected to a re-examination.

Prof. Moraht and Dr. Wischin have therefore taken up the study of the compounds of osmium with oxygen, sulphur, and the halogens, employing material of a very high degree of purity, and the results of their investigation are both novel and interesting.

Work with osmium compounds is endowed with peculiar personal danger to the chemist, owing to the great facility exhibited under the most various conditions for the formation of the tetroxide OsO_4, a substance which boils at 100° C., and is very volatile at the ordinary temperature, and which attacks the skin, the lungs, and particularly the eyes with most serious consequences.

The material started with was a comparatively pure sample of the best known salt containing osmium, potassium osmate, $K_2OsO_4.2H_2O$. This salt was further purified by distillation with nitric acid or aqua regia and absorption of the liberated tetroxide vapours in a solution of caustic potash. The dark brown solution of potassium perosmate thus formed was largely diluted with water, and reduced to osmate by the addition of alcohol. After the expiration of about twenty-four hours almost the whole of the osmium had separated in the form of beautiful little crimson octahedrons of the salt $K_2OsO_4.2H_2O$, which, after washing with dilute alcohol, proved to be quite free from impurity, showing no trace of iridium.

Previous observers have noticed that an aqueous solution of *potassium osmate*, K_2OsO_4, is most remarkably affected by sunlight, a rapid decomposition being brought about with deposition of a black precipitate to which the composition $OsO_2.2H_2O$ has been ascribed. The specimens experimented with, however, undoubtedly contained iridium, and it was therefore of interest to investigate the action of sunlight upon solutions of the pure salt just described. When the crimson octahedrons of pure $K_2OsO_4.2H_2O$ were dissolved in cold water, and the clear reddish violet-coloured solution was exposed to direct sunshine, no evidence of change was apparent for several days, but the moment the vessel containing the solution was immersed in a bath of boiling water, while in bright sunshine, decomposition commenced, and a black precipitate rapidly accumulated, until after the expiration of two or three hours the whole of the osmium present was deposited. As there is a marked tendency for the production of the noxious fumes of osmium tetroxide during this decomposition of the hot osmate solution by the waves of light it is best to take the precaution of reducing their amount to a minimum by the addition of a little alcohol, which acts as a strong reducing agent under these circumstances, and by passing a stream of hydrogen through the solution during the whole operation. The precipitate is usually so finely divided that considerable difficulty is experienced in separating it from the solution. The filtration succeeds best when the filter is previously moistened with dilute acetic acid, when a clear colourless filtrate is usually at once obtained. The precipitate cannot be dried in a warm air bath, as it is largely converted thereby into the volatile osmium tetroxide. It may safely, however, be dried over phosphoric anhydride in the vacuum of an air-pump.

The accurate analysis of an insoluble substance of the nature of this precipitate, and containing a metal such as osmium, which so readily oxidises to the volatile tetroxide, is a task of exceptional difficulty. The usual method of reduction to metal in a stream of hydrogen is insufficient, for more or less of the tetroxide is always formed during the process, necessitating the use of an absorption apparatus containing a solution of caustic potash, placed in front of the tube containing calcium chloride to absorb the water formed. The difficulty is, then, how to estimate the small quantity of osmium thus dissolved in the large excess of alkali. It was eventually found that the weak electric current from three Daniell's cells precipitates the whole of the osmium from such a solution, contained in a nickel dish which forms the negative electrode, in the form of pure *osmium dioxide*, OsO_2, which may conveniently be dried *in vacuo* over phosphoric anhydride and weighed as such.

By this mode of analysis the interesting fact was eventually elicited, that the black insoluble substance formed by the action of light upon a hot solution of potassium osmate is not, as was previously supposed, a hydrate of osmium dioxide of the composition $OsO_2.2H_2O$, but is no other than free *osmic acid* itself, the hydrate of osmium trioxide, $OsO_3.H_2O$ or H_2OsO_4. Osmic acid is thus formed by the direct action of water, under the influence of sunlight and slight rise of temperature, upon the potassium salt. This remarkable change is expressed by the simple equation :

$$K_2OsO_4 + 2H_2O = H_2OsO_4 + 2KOH.$$

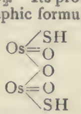
The liquid, as soon as the change commences, is observed to exhibit a strong alkaline reaction, becoming, as indicated in the equation, a solution of caustic potash. It is singular that the presence of alcohol and the passage of a current of hydrogen during the reaction do not cause any reduction, serving only to hinder the further oxidation to the state of tetroxide. Indeed, if the crimson octahedral crystals of potassium osmate are covered in sunshine with warm alcohol and a current of hydrogen is allowed to bubble through the liquid, no trace of blackening is observed upon the faces of the crystals. The moment water is added, however, decomposition is immediately brought about.

Osmic acid, H_2OsO_4, is a soot-black powder, which fumes strongly in moist air, owing to its rapid conversion into the volatile osmium tetroxide, OsO_4, but which is quite permanent at the ordinary temperature when preserved under water containing alcohol. It dissolves readily in nitric acid with formation of the hydrate of osmium tetroxide, the so-called per-osmic acid. Cold hydrochloric acid attacks it but very slightly. Upon warming, however, it is entirely soluble, forming an olive-green liquid, which will be subsequently considered, with liberation of a small quantity of chlorine. Sulphuric acid does not attack it. Osmic acid reacts in a most energetic and interesting manner with sulphuretted hydrogen gas. Even in the dry state at the ordinary temperature the reaction proceeds with considerable violence. If the experiment is conducted in a piece of combustion tubing, upon which a bulb has been blown for the reception of the osmic acid, the moment that the gas enters the tube the whole of the black powder immediately becomes incandescent, and drops of water and a large quantity of free sulphur are deposited in the portion of the tube not heated by the reacting substances. The residual product of the reaction is a brown powder, which has been found to be a hydrated oxysulphide of osmium of the composition $2OsSO.H_2O$.

The reaction occurs in accordance with the equation—

$$2H_2OsO_4 + 4H_2S = 2OsSO.H_2O + 5H_2O + 2S.$$

This *oxysulphide of osmium* is soluble in acids with decomposition, even sulphuric acid decomposing it with evolution of sulphuretted hydrogen. It possesses acid properties, for it liberates carbon dioxide from carbonate of soda and sulphuretted hydrogen when fused with sulphide of potassium. It would, moreover, appear to contain SH groups, for it yields mercaptan upon treatment with soda and ethyl iodide, the osmium being reduced to the dioxide OsO_2. Its probable constitution is therefore represented by the graphic formula :—



When this oxysulphide is warmed in dry sulphuretted hydrogen another violent reaction occurs, the whole mass again becomes incandescent, and the whole of the oxygen is eliminated in the form of water. The product of this second reaction with sulphuretted hydrogen is pure *osmium disulphide* OsS_2.

$$Os_2O_3(SH)_2 + 2H_2S = 2OsS_2 + 3H_2O.$$

Of the *halogen* compounds of osmium only the chlorides have been at all investigated, chiefly by Claus, whose observations may be summarised in a few words.

When finely-powdered metallic osmium is heated in a stream of dry chlorine sublimates are formed. The first chlorine compound formed is chromous-green in colour, but is only produced to a very slight extent. There is next deposited a dense black sublimate, and finally a smaller quantity of a sublimate of the colour of red lead. None of these three chlorine compounds are crystalline. Claus subsequently stated that the lowest chloride $OsCl$, is a bluish-black solid when isolated, and forms a dark bluish-violet solution ; the sesquichloride Os_2Cl_3 is reddish-brown in the solid state, and gives with water a rose-red coloured solution, and the dichloride $OsCl_2$ is the compound which exhibits the colour of red-lead, and yields a lemon-yellow solution

These observations of Claus are completely confirmed by the experiments of Prof. Moraht and Dr. Wischin, who, however, have extended them, and have been able to isolate other and higher chlorides of osmium.

They commenced by warming a large quantity of the free osmic acid above described for two days upon a water-bath with concentrated hydrochloric acid, the flask in which the reaction was conducted being connected with an upright condenser. A little alcohol was added in order to prevent the formation of osmium tetroxide. The osmic acid eventually entirely dissolved with formation of the dark olive-green coloured solution previously incidentally mentioned, a little chlorine being evolved at the commencement of the operation. It was found impossible to evaporate the solution upon the water-bath without decomposition, but evaporation *in vacuo* over sulphuric acid and solid caustic potash, the latter to absorb the hydrochloric acid, succeeded admirably. The solid left after complete evaporation consisted of well formed crystals which assumed the habit of six-sided pyramids. These crystals were dark olive-green in colour when moist, but when the last traces of superfluous water were removed, exhibited a bright vermilion colour. They were readily soluble in water and alcohol, the solutions being coloured dark green, and the salt may be recrystallised from these solvents. Upon analysis they were found to consist of the chloride Os_2Cl_7 crystallised with seven molecules of water.

This chloride of osmium, $Os_2Cl_7.7H_2O$, would appear to be a molecular compound of the *trichloride*, $OsCl_3$, and the *tetrachloride*, $OsCl_4$. For when potassium chloride solution is added to the solution of the crystals in alcohol, a precipitate of brilliant red octahedrons and cubes of potassium osmichloride, K_2OsCl_6, is obtained, showing the presence of *osmium tetrachloride*, $OsCl_4$. Moreover, when the precipitate is separated by filtration, and the filtrate concentrated by evaporation *in vacuo*, dark green crystals of the *trichloride*, $OsCl_3$, are deposited containing three molecules of water of crystallisation.

During the reduction of these crystals of the trichloride in a current of hydrogen for the purposes of analysis, a small quantity of a white sublimate was obtained, which probably consisted of the *octo-chloride*, $OsCl_8$, corresponding to the tetroxide OsO_4.

Bromine does not react with osmium with anything like the energy of chlorine. The free elements do not appear to combine at all, even at moderately high temperatures. Only a small quantity of a sublimate of a dark brown colour is obtained by passing bromine vapour over osmic acid. This sublimate dissolves to a brown solution in water, which, however, rapidly decomposes with deposition of a black precipitate.

When osmic acid, H_2OsO_4, is treated with hydrobromic acid in the manner just described in the case of hydrochloric acid a similar reaction occurs with formation of a clear reddish-brown solution which yields, upon evaporation *in vacuo* over sulphuric acid and solid caustic potash, small crystals of a molecular compound of the *tribromide*, $OsBr_3$, and the *hexabromide*, $OsBr_6$, together with six molecules of water of crystallisation. These crystals of $Os_2Br_9.6H_2O$ are dark reddish-brown in colour and exhibit a beautiful metallic lustre. They are quite stable when preserved in a dry atmosphere, but rapidly deliquesce in moist air.

Iodine appears to possess even less affinity for osmium than bromine. When, however, osmic acid is treated with hydriodic acid a deep greenish-brown solution is obtained which deposits *in vacuo* dark violet rhombohedrons, exhibiting a brilliant metallic lustre, consisting of the anhydrous *tetra-iodide of osmium*, OsI_4. This iodide, the only one containing osmium yet prepared, is permanent in a dry atmosphere at the ordinary temperature, but rapidly deliquesces like the bromide when exposed to moist air.

In relative stability the chloride bromide and iodide of osmium above described exhibit a gradation such as would be expected from the relations between the halogen elements themselves. The iodide is readily dissociated by slightly raising the temperature, and upon the addition of water is decomposed with the deposition of a black precipitate containing the metal. A similar decomposition occurs, although much more slowly, in case of the bromide. The chloride, however, is well-nigh permanent under these conditions, only exhibiting traces of decomposition after the lapse of a considerable time. A. E. TUTTON.

REDUCTION OF TIDAL OBSERVATIONS.[1]

THE tidal oscillation of the ocean may be represented as the sum of a number of simple harmonic waves which go through their periods approximately once, twice, thrice, four times in a mean solar day. But these simple harmonic waves may be regarded as being rigorously diurnal, semi-diurnal, terdiurnal, and so forth, if the length of the day referred to be adapted to suit the particular wave under consideration. The idea of a series of special scales of time is thus introduced, each time-scale being appropriate to a special tide. For example, the mean interval between successive culminations of the moon is 24h. 50m., and this interval may be described as the mean lunar day. Now there is a series of tides, bearing the initials M_1, M_2, M_3, M_4, &c., which go through their periods rigorously once, twice, thrice, four times, &c., in a mean lunar day. The solar tides, S, proceed according to mean solar time, but, besides mean lunar and mean solar times, there are other special time scales appropriate to the other tides.

The process of reduction consists of the determination of the mean height of the water at each of twenty-four special hours, and subsequent harmonic analysis. The means are taken over such periods of time that the influence of all the tides governed by other special times is eliminated.

The process by which the special hourly heights have hitherto been obtained is the entry of the heights observed at the mean solar hours in a schedule so arranged that each entry falls into a column appropriate to the nearest special hour. Schedules of this kind were prepared by Mr. Roberts for the Indian Government.[1] The successive rearrangements for each sort of special time were made by recopying the whole of the observations time after time into a series of appropriate schedules. The mere clerical labour of this work is enormous, and great care is required to avoid mistakes.

All this copying might be avoided if the observed heights were written on movable pieces. But a year of observation gives 8760 hourly heights, and the orderly sorting and resorting of nearly 9000 pieces of paper or tablets might prove more laborious and more treacherous than recopying the figures.

The marshalling of movable pieces might, however, be reduced to manageable limits if all the twenty-four observations pertaining to a single mean solar day were moved together, for the movable pieces would be at once reduced to 365, and each piece might be of a size convenient to handle.

The realization of this plan affords the subject of this paper, and it appears that not only is all desirable accuracy attainable, but that the other requisite of such a scheme is satisfied, namely, that the whole computing apparatus shall serve any number of times and for any number of places.

The first idea which naturally occurred was to have narrow sliding tablets which should be thrown into their places by a number of templates. It is unnecessary to recount all the trials and failures, but it will suffice to say that the slides and templates would require the precision of a mathematical instrument if they are to work satisfactorily, and that the manufacture would be so expensive as to make the price of the instrument prohibitive.

The idea of making the tablets or strips to slide into their places was accordingly abandoned, and the strips are made with short pins on their under sides, so that they can be stuck on to a drawing board in any desired position. The templates, which were also troublesome to make, are replaced by large sheets of paper with numbered marks on them to show how the strips are to be set. The guide sheet is laid on a drawing board, and the pins on the strips pierce the paper and fix them in their proper positions.

The strip belonging to each mean solar day is divided by black lines into 24 equal spaces, intended for the entry of the hourly heights of water. The strip is nine inches long by $\frac{1}{2}$ inch wide, and the divisions ($\frac{3}{8}$ by $\frac{1}{2}$) are of convenient size for the entries. There was much difficulty in discovering a good material, but after various trials artificial ivory, or xylonite, was found to serve the purpose. Xylonite is white, will take writing with Indian ink or pencil, and can easily be cleaned with a damp cloth. It is just as easy to write with liquid Indian ink as with ordinary ink, which must not be used, because it stains the surface.

The observations are to be treated in groups of two and a half lunations or 74 days. A set of strips, therefore, consists of 74, numbered from 0 to 73 in small figures on their flat ends.

If a set be pinned horizontally on a drawing board in vertical column, we have a form consisting of rows for each mean solar day, and columns for each hour. The observed heights of the water are then written on the strips.

When the twenty-four columns are summed and divided by the number of entries we obtain the mean solar hourly mean heights. The harmonic analysis of these means gives the mean solar tides. But for evaluating the other tides the strips must be rearranged, and to this point we turn our attention.

Let us consider a special case, that of mean lunar time. A mean lunar hour is about 1h. 2m. m.s. time; hence the 12h. of each m.s. day must lie within 31m. m.s. time of a mean lunar hour. The following sample gives the incidence to the nearest lunar hour of the first few days in a year:—

---

[1] "On an Apparatus for facilitating the Reduction of Tidal Observations." By G. H. Darwin, F.R.S., Plumian Professor and Fellow of Trinity College, Cambridge. A paper read before the Royal Society on December 15, 1892.

[1] An edition of these computation forms was reprinted by aid of a grant from the Royal Society, and is sold by the Cambridge Scientific Instrument Company, but only about a dozen copies now remain.

Mean solar time. d.	h.		Mean lunar time. d.	h.
0	12	=	0	12
1	12	=	1	11
2	12	=	2	10
3	12	=	3	9
4	12	=	4	8
5	12	=	5	8
6	12	=	6	7
7	12	=	7	6
&c.			&c.	

The successive 12h. of m.s. time will march retrogressively through all the twenty-four hours of m. lunar time.

Now, if starting from strip 0, we push strip 1 one division to the left, strip 2 two divisions to the left, and so on, the entries on the strips will be arranged in columns of approximately lunar time.

The rule for this arrangement is given by marks on a sheet of paper 18 in. broad; these marks consist of parallel numbered steps or zigzags showing where the ends of each strip are to be placed so as to bring the hourly values into their proper places.

At the end of a lunation mean solar time has gained a whole day over mean lunar time, and the 12h. solar again agrees with the 12h. lunar. On the guide sheet the zigzag which takes its origin at the left end of strip 0 has descended diagonally from right to left until it has reached the left margin of the paper, and a new zigzag has begun on the right margin.

When the strips are pinned out following the zigzags on the sheet marked M, the entries are arranged in 48 columns, but the number of entries in each column is different. The 48 incomplete columns may be regarded as 24 complete ones, appertaining to the 24 hours.

Harmonic analysis of the 24 means of the complete columns gives the required tidal constants. It must be remarked, however, that as the incidence of the entries is not exact in lunar time, investigation is made in the paper of the corrections arising out of this inexactness.

The explanation of the guide sheet for lunar time will serve, *mutatis mutandis*, for all the others.

The zigzags have to be placed so as to bring the columns into exact alignment, and printers' types provide all the accuracy requisite.

To guard against the risk of the computer accidentally using the wrong sheet, the sheets are printed on coloured paper, the sequence of colours being that of the rainbow. The sheets for days 0 to 73 are all red; those for days 74 to 74 + 73, or 147, are all yellow; those for days 148 to 148 + 73, or 221, are green; those for days 222 to 222 + 73, or 295, are blue; and those for days 296 to 296 + 73, or 369, are violet.

Thus, when the observations for the first 74 days of the year are written on the strips all the sheets will be red; the strips will then be cleaned, and the observations for the second 74 days written in, when all the guide sheets will be yellow, and so on.

The paper also gives another considerable abridgement of the process of harmonic analysis, which is independent of the method of arrangement just sketched.

In the Indian computation forms the mean solar hourly heights have been found for the whole year, and the observations have been rearranged for the evaluation of certain other tides governed by a time scale which differs but little from the mean solar scale. It is now proposed to break the mean solar heights into sets of 30 days, and to analyse them, and next to harmonically analyse the 12 sets of harmonic constituents for annual and semi-annual inequalities. By this plan the harmonic constants for 11 different tides are obtained by one set of additions. In fact, we now get the annual, semi annual, and solar elliptic tides, which formerly demanded much troublesome extra computation. A great saving is secured by this alone, and the results are in close agreement with those derived from the old method.

An abridged method of evaluating the tides of long period MSf, Mf, Mm, is also given. The method is less accurate than that followed hitherto, but it appears to give fairly good results, and reduces the work to very small dimensions.

The advantages of the method proposed in the present paper may be best realized by a comparison of the amount of work entailed in the reduction of a year's tides as it has hitherto been carried out by the Indian Survey at Poona, and what it will be under the new method.

It has been usual in the Indian reductions to use three digits in expressing the height of water, and there have been fifteen series, or even more. It follows from a simple multiplication that the computer has had to write 394,000 figures in reducing a year of observation. This does not include the evaluation of the annual and semi-annual tides, so that we may say that there have been about 400,000 figures to write.

It is now proposed to express the heights by two digits, and they only have to be written once, and the number of figures to write is 17,500; accordingly the writing of 382,000 figures is saved.

In the old method the computer had to add together all the digits written, say, 394,000 additions of digit to digit.

It is now proposed to use twenty-four hourly values in three series, viz. S, M, and MS, and twelve two-hourly values in eight others, and the number of additions comes to 123,000. Thus 270,000 additions are saved.

We may say that formerly there were about 800,000 operations (writing and addition), and that in the present method there will be about 140,000. This estimate does not include a saving of several thousands of operations in obtaining the tides of long period. It may therefore be claimed that the work formerly bestowed on one year of observation will now reduce at least five years, and that the results are equally trustworthy.

The manufacture of the computing strips of xylonite is rather expensive, but as it formerly cost in England rather more than £20 to reduce a year of observation, the cost of the apparatus will be covered by the saving in the reduction of a single year, and it will serve for any length of time.

The apparatus, together with computation forms, will be on sale with the Cambridge Scientific Instrument Company at a price of about £8.

It is proper to mention that Dr. Börgen has devised and used a method for attaining the same end as that aimed at in this paper. He has prepared sheets of tracing paper with diagonal lines on them, so arranged that when any sheet is laid on the copy of the observations written in daily rows and hourly columns, the numbers to be summed are found written between a pair of lines. This plan is inexpensive and has considerable advantages, but the chance of error is no doubt increased by the fact that the lines of addition are diagonal, and because figures seen through tracing-paper are comparatively faint.

THE HARVARD COLLEGE OBSERVATORY.

THE forty-seventh annual report of the director of the astronomical observatory of Harvard College, for the year ending October 31, 1892, by Prof. E. C. Pickering, has been issued. We reprint the following passages:—

The number of photographs taken with the eight-inch Draper telescope is 2777. The number taken in Peru with the Bache telescope is nearly two thousand, of which 601 have been received in Cambridge. The examination of these plates has as usual led to the discovery of a large number of interesting objects. Ten variable stars, U Delphini, S Pegasi, T Aquarii, R Crateris, R Carinæ, S Canis Minoris, S Carinæ, R Ophiuchi, X Ophiuchi, and Espin's variable star in Auriga in addition to the thirty-seven previously announced have the hydrogen lines bright in their spectra. Seven new variable stars have been discovered this year by means of this property. The number of stars of the fifth type has been increased by eight, making the total number now known of these objects forty-five. The hydrogen line F was shown to be bright in the spectra of six stars in addition to those already known. Photographs have been obtained of the spectra of eight planetary nebulæ showing bright lines. The spectrum of the nebula surrounding thirty Doradus is unlike that of other gaseous nebulæ. The star A. G. C. 20,937 has a somewhat similar spectrum. Five stars have been shown to have spectra of the fourth type. All of these peculiarities have been detected by Mrs. Fleming except in the cases of one of the known variables, one of the planetary nebulæ, and two of the stars of the fourth type, which were found by Mr. A. E. Douglass, in Peru, before the plates were sent to Cambridge.

The amount of valuable material accumulated with these instruments is continually increasing, and has proved useful in many cases in studying the history of newly-discovered objects.

The brightness for several years past of stars suspected of variability has been furnished to various astronomers. Plates have been sent to the Lick and Amherst Observatories and to the Smithsonian Institution for special investigations. From one of them a new variable star in Aries was discovered by Prof. Schaeberle. It is hoped that this use of our plates may increase in the future. A large number of photographs were taken of the new star in Auriga. An examination of the older photographs showed that the region containing it had been photographed eighteen times from November 3, 1885, to November 2, 1891, and that it was then apparently fainter than the thirteenth magnitude. It appeared upon five plates taken between December 16, 1891, and January 31, 1892. After its discovery it was photographed on sixty-five chart plates and thirty-six spectrum plates, until April 6, when it became too faint to be visible in the encroaching twilight. All of these plates have been carefully studied and measured. Twenty-one charts and fifteen spectrum plates of this object have been taken since its reappearance in September, 1892. On these last plates, the spectrum is shown to resemble that of a planetary nebula.

Many photographs of the lunar eclipse of November 15, 1891, were taken both at Cambridge and at the Boyden observing station near Arequipa, Peru. The examination of these photographs for the detection of a possible lunar satellite led only to a negative result.

The number of photographs taken with the 11-inch Draper telescope is 996. They include 372 spectra of β Aurigæ to determine the law of periodic doubling of the lines. 244 of these images show the lines double so that the separation can be measured. In like manner 208 spectra of ζ Ursæ Majoris have been photographed, and in 49 of them the lines are separated widely enough to be measured. A similar study has been made of the new star in Auriga, of β Lyræ, of 11 Monocerotis, and of some other stars having peculiar spectra. Photographic charts have also been obtained of numerous variable stars, stars having large proper motion, clusters and stars having peculiar spectra to determine their parallax if it is perceptible.

Boyden Department.

In establishing the fund that bears his name, Mr. Boyden desired to secure an astronomical station where the effects due to the atmosphere would be greatly diminished. This has now been successfully accomplished in the Harvard Station at Arequipa, Peru, where the effect of the air is no longer as heretofore the principal obstacle to progress in astronomy. Instead of this the limit is now the size and excellence of our instruments. A great advance would probably be made in our knowledge of the planets, and perhaps of the fixed stars, if a telescope of the largest size could be mounted under such favourable conditions.

This station has continued in charge of Prof. W. H. Pickering. The instruments chiefly employed have been the 13-inch telescope, the 8-inch Bache telescope, and a photographic camera having an aperture of 2½ inches. The first of these instruments has been largely devoted to visual work, for which unusual advantages are afforded by the transparency and steadiness of the air at this station. Many interesting results have been derived from the observations made of the moon and various planets. The observations of the moon relate to Plato and other regions, which have been carefully examined, and also to the systems of bright streaks visible at full moon. The markings of Mercury have been studied, and this investigation appears to confirm Schiaparelli's view that the rotation of Mercury on its axis occupies the same time as its revolution in its orbit. Although this planet appears to have no atmosphere, the markings upon it are very faint compared with those upon the moon. Venus was micrometrically studied near its inferior conjunction with regard to its diameter, polar compression, and the refractive effect of its atmosphere. No permanent markings could be detected. An extensive series of observations was made upon Mars. The relative positions of 92 points upon its surface were determined by the micrometer. More than forty minute black points were discovered, provisionally designated as lakes. The polar compression of the planet was measured, and appeared to be greater than that indicated by theory, which may be due to an excess of cloud in the equatorial regions. The presence of the dark and narrow streaks called canals by Schiaparelli has been confirmed and various measurements of them have been made. The clouds projecting beyond the limb, and terminator, discovered at the Lick Observatory, have been studied, and their height has been found to be at least twenty miles. The relative colours of different portions of the planet have been minutely observed. Two large dark blue areas have been detected, and other portions have been noticed to be subject to gradual changes of colour.

Many new double stars were found in a survey of the heavens south of 30°, between 12h. and 18h. The August occultation of Jupiter was observed both visually and photographically, as was also the new star in Auriga and Swift's comet, the photographs of which showed detail not noticeable in the visual observations.

With the camera, having the aperture 2½ inches, very satisfactory photographs have been obtained of the Magellanic clouds, showing their composition to be partly of stars and partly of nebulous matter; also the spiral structure of the larger of the two clouds.

Meteorological observations are regularly carried on. Stations have been established at Mollendo, 100 feet above sea level, at La Joya, the elevation of which is 4,150 feet, at the observing station, 8,060 feet high, at the Chachani Ravine 16,650 feet high, where numerous miscellaneous observations have been made. Notwithstanding the great height of the last-named station, it can be reached by a mule path, and a hut has been erected where the observers can pass the night. A survey of the Arequipa valley and neighbouring mountains has been made, depending on two separate base lines. The heights of the mountains have been measured, and in some cases the result has been checked by a mercurial barometer.

The Bruce Photographic Telescope.

This instrument, which if successful will be in many respects the most powerful in the world, is now rapidly approaching completion. The eight surfaces of its objective have been ground and polished so that it could be tested on a star. The results were satisfactory, although, of course, no definite opinion can be formed until the final corrections are applied. The focal length proved to be that desired within half of one per cent. Plans have been made and the foundations laid for a one-story brick building with a sliding roof, in which it will be erected during its trial in Cambridge. After this it is proposed to send it to the Arequipa station in Peru.

Photographs have been taken with the transit photometer on 192 evenings, and when clear, throughout the entire night. With this instrument images are obtained of all stars brighter than the sixth magnitude which cross the meridian during the night. The value of this work was illustrated when the new star in Auriga was discovered in February, 1892. It then appeared that this object had been photographed on twelve nights since December 10, 1891, while no trace of it was visible on thirteen plates covering this region and taken before December 2, 1891. The only knowledge that exists of its changes of light during the six weeks in which it remained undiscovered is furnished by these photographs and those taken with the 8-inch telescopes. It was also photographed with the transit photometer on twelve nights after its discovery. Of the forty thousand standard stars of the tenth magnitude about eight thousand have been selected by Miss E. F. Leland during the past year, making eleven thousand in all.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—In the Chemical Department Prof. Odling is lecturing on the glucoses, Mr. Fisher on inorganic chemistry, Dr. Watts on organic chemistry, and Mr. Veley on physical chemistry. There are about sixty students working in the laboratories, and a few of the senior men are engaged in research.

Among the apparatus belonging to the late Duke of Marlborough, presented by the Duchess, are three large spectroscopes by Hilger, one having five prisms, another being a direct vision spectroscope 5 feet 6 inches in length, two balances by Deleuil; a mercury pump by Alvergniat, Dumas' vapour density apparatus, Thomson's electrometer gramme machine, large Rhumkorf coil and a quantity of valuable glass apparatus. There are besides a number of specimens of compounds of rare earths.

The Regius Professor of Medicine has placed his pathological laboratory under the direction of the lecturer in Pharmacology. Dr. Ritchie of Edinburgh is carrying out in it some researches in Bacteriology. The Chemical Club started last term by some of the senior men continues to hold meetings weekly for the discussion of recent chemical investigations. Mr. Ingham of Merton is secretary. The meetings are well attended and useful.

Mr. R. T. Günther, B.A., Demy of Magdalen College, has been elected to the Naples Biological Scholarship for the ensuing year.

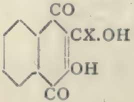
CAMBRIDGE.—Mr. H. Bury, Fellow of Trinity College, has been appointed by the Board for Biology and Geology to the use of a table at the Naples Zoological Station for March and April, 1893.

The Boards for Biology and Geology, and for Physics and Chemistry, have reported in favour of extending to Part I. of the Natural Sciences Tripos the plan already adopted for Part II., namely, the substitution of distinct papers in each scientific subject, instead of papers each of which contains questions in all the subjects. They propose that the change come into operation in 1894.

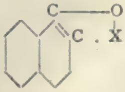
SOCIETIES AND ACADEMIES.

LONDON.

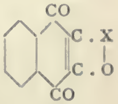
Chemical Society, January 19.—Prof. A. Crum-Brown, President, in the chair.—The following papers were read:—Glucinum, Part I. The preparation of glucina from beryl, by J. Gibson. The methods at present in use for preparing pure glucina from beryl are tedious and difficult to apply on the large scale, as the mineral, which contains but a small quantity of glucinum, has to be reduced to a very fine powder before being treated by the reagents usually employed for the decomposition of refractory silicates. The author has worked out a process which greatly facilitates the preparation of glucina. If the coarsely-ground beryl is heated in an iron vessel with six parts of ammonium hydrogen fluoride, complete decomposition occurs below a red heat. The product contains the aluminium and most of the iron as insoluble fluoride and oxide respectively, together with glucinum fluoride, which dissolves on extraction with water. In order to remove the last traces of iron from crude glucina, advantage is taken of the fact that the precipitation of a lead or mercuric salt by ammonium sulphide effects by mass action the complete separation of small quantities of iron which may be present in the solution.—The determination of the thermal expansion of liquids, by T. E. Thorpe. The author describes various improvements in the ordinary dilatometrical method of determining the thermal expansion of liquids. Amongst these the most important is the application of a device frequently employed in the construction of standard thermometers, and consisting in enlarging the bore of the dilatometer stem at some point. On such an instrument the positions of the 0° and 100° points may be determined irrespectively of its range, and the thermometer, and the column of liquid in the dilatometer stem may be totally immersed in a bath of moderate size, thus doing away with corrections for the emergent columns of the two instruments. The methods of constructing, calibrating, and using the dilatometers are described, together with the baths employed in heating them.—The determination of the thermal expansion and specific volume of certain paraffins and paraffin derivatives, by T. E. Thorpe and L. M. Jones. The authors give the data relating to a number of hydrocarbons, alcohols, ketones, and other derivatives of the paraffins. The results show a fairly satisfactory agreement, in most cases, with the values calculated by Lossen's formula, but all the observed specific volumes, with the exception of that of propionic anhydride, differ considerably from those calculated by means of Kopp's values.—The hydrocarbons derived from dipentene dihydrochloride, by W. A. Tilden and S. Williamson. The dihydrochloride, $C_{10}H_{16}2HCl$ melting at 50°, prepared by the action of moist hydrogen chloride on optically active turpentine, is known to be identical with that obtained from the active citrenes (limonenes) or from inactive "dipentene." On heating it with aniline, an oil is obtained which has hitherto been supposed to consist essentially of dipentene; on oxidising it, however, a certain proportion of aromatic acids is obtained. These acids are not formed on oxidising the active limonenes or pure dipentene with nitric acid; their formation in the previous case is, however, satisfactorily explained by the authors, who find that the dipentene obtained from the dihydrochloride contains large proportions of cymene, terpinene, terpinolene, and a small quantity of a saturated paraffinoid hydrocarbon boiling at about 155°.—Sulphonic derivatives of camphor, by F. S. Kipping and W. J. Pope. The authors have succeeded in preparing camphorsulphonic acid, $C_{10}H_{15}O.SO_3H$, a compound hitherto unknown, by the direct action of anhydrosulphuric acid or chlorosulphonic acid on camphor. The acid is purified by the conversion of its sodium salt into camphorsulphonic chloride, $C_{10}H_{15}O.SO_2Cl$; the latter substance is apparently obtained in optically different modifications which are separated only with considerable difficulty. The sulphonic chloride is readily hydrolysed on boiling with water, yielding the sulphonic acid from which a series of well-defined salts has been obtained. The action of anhydrosulphuric acid on bromocamphor results in the formation of bromocamphorsulphonic acid; this on suitable treatment yields a sulphonic chloride, $C_{10}H_{14}BrO.SO_2Cl$, which crystallises in magnificent colourless octahedra, melting at 136–137°. A bromocamphorsulphonic chloride of similar composition has been previously described by Marsh and Cousins as a "black, semi-crystalline tar;" a repetition of their work shows this to be merely an impure form of the substance now described. The corresponding chlorocamphorsulphonic chloride described by Marsh and Cousins as a "microcrystalline, black solid," crystallises in massive colourless octahedra when pure; it melts at 123–124°, and has a specific rotatory power $[\alpha]_D = +110°$. The authors describe a number of salts and derivatives of these sulphonic acids.—The preparation of dinitro-α-naphthylamine $[NH_2 : NO_2 : NO_2 = 1 : 2 : 4]$ from its acetyl and valeryl derivatives, by R. Meldola and M. O. Forster. Meldola's process of preparing dinitro-α-naphthylamine from α-acetnaphthalide having been questioned, the authors have re-investigated the method and confirm it in all respects; they give full working details of the process, and show that the same product is obtained by the nitration and subsequent hydrolysis of valeronaphthalide.—Thionyl bromide, by J. Hartog and W. E. Sims. Thionyl bromide is obtained as a heavy, crimson liquid by the action of sodium bromide on thionyl chloride; its colour is possibly due to impurity. At 150° the bromide decomposes, yielding bromine and sulphur bromides.—Desulphurisation of the substituted thioureas, by A. E. Dixon. The monosubstituted thioureas are all desulphurised on boiling with an alkaline solution of a lead salt; the same is true of disubstituted thioureas containing benzenoid groups, but not if such groups be absent. The tri- and probably also the tetra-substituted thioureas are not desulphurised under similar conditions. A number of new thioureas are described.—Salts of active and inactive glyceric acid: the influence of metals on the specific rotatory power of active acids, by P. F. Frankland and J. R. Appleyard. The authors have prepared and analysed a number of salts both of inactive and dextro-glyceric acid; the solubilities and specific rotatory powers are also given. Certain remarkable numerical relations apparently exist between the rotations of many of the salts; these should have considerable bearing on the vexed question of multiple rotation, and will be discussed after they have been submitted to a more detailed investigation.—Dibromo-β-lapachone, by S. C. Hooker and A. D. Gray. Monobromo-β-lapachone cannot be converted into dibromo-β-lapachone by the action of bromine alone; the formation of the latter derivative in the preparation of monobromo-β-lapachone from lapachol, is due to the production and subsequent decomposition of an additive compound of monobromo-derivative and hydrogen bromide.—The conversion of para- into ortho-quinone derivatives, by S. C. Hooker. Both in the lapachol and other groups, compounds derived from α-naphthaquinone, of the type represented by formula I., are far more readily converted, by the action of acids, into anhydrides derived from β-naphthaquinone (II.) than into anhydrides of the α-quinone type (III.).



I.



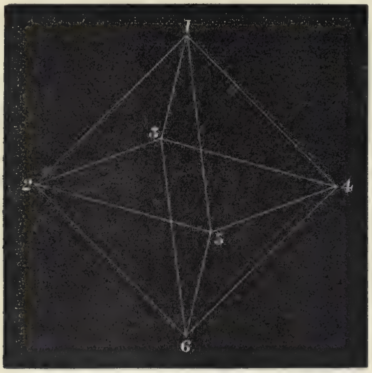
II.



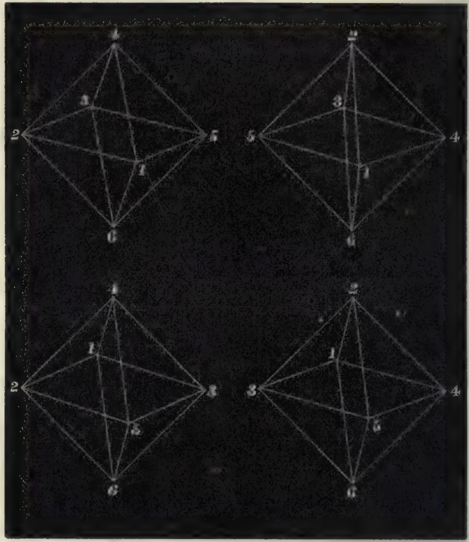
III.

—The nitro-derivatives of phenolphthalein, by J. A. Hall The author has prepared dinitro- and tetranitro-phenolphthalein, and describes their properties.—A method for the preparation of acetylene, by M. W. Travers. Calcium carbide may be prepared by heating a mixture of sodium, gas carbon, and calcium chloride for half an hour at bright redness in an iron bottle. The carbide thus obtained yields acetylene on treatment with water. 240 c.c., half the theoretical quantity, of acetylene is obtained for every gram of sodium used in the preparation of the carbide.

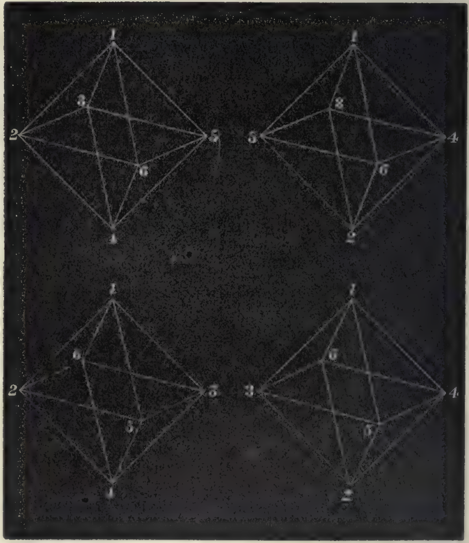
Mathematical Society, February 9.—Mr. A. B. Kempe, F.R.S., President, in the chair.—The following communications were made:—The Harmonics of a Ring, by Mr. W. D. Niven, F.R.S. This paper treats of the potential functions of an anchor ring, and explains how problems to which those functions are applicable may be solved for two coaxal rings. The proposition on which the method depends establishes that the ring harmonics of any degree may be derived from their predecessors of lower degree by simple differentiations with regard to the radius of the dipolar circle of the ring and the distance of a fixed point from the plane of this circle. Ultimately the harmonics depend upon the potential at any point due to a distribution on the circle either uniform or varying as a circular function of the arc. Now the potential due to such distribution on a circle B may readily be expressed in terms of the harmonics pertaining to a coaxal circle A, and hence any harmonic pertaining to B, and therefore any series of such harmonics, may be expressed in a series pertaining to A. In the latter form they are suitable for the application of surface conditions at any ring whose dipolar circle is A. The application worked out in the paper is the problem of the influence of two electrically charged coaxal rings upon one another. It is also shown how the same problem may be solved for a ring and sphere, symmetrically situated as regards the axis.—The group of thirty cubes composed by six differently coloured squares, by Major MacMahon, R.A., F.R.S. Selecting any one of the thirty cubes at pleasure it is possible to select eight of the remaining twenty-nine which in reference to the cube selected have a very peculiar and interesting property. It is possible to form the eight cubes into a single cube in such wise that contiguous faces of the cubes are similarly coloured, and also so that the resulting cube has the appearance of the *selected* cube in regard to the colouring of its faces. To each cube of the thirty belong in this way eight other cubes, the selection of the eight cubes being unique. For the examination of this property the selected cube is transformed into an octahedron by joining the middle point of each face to the middle points of the adjacent faces; a regular octahedron with six differently coloured summits is thus obtained. Each triangular face is determined by three differently coloured summits, and exactly eight other octahedra are obtained by circular substitutions performed on the three colours which determine a face; in regard to the eight faces there are eight clock-wise and eight counter clock-wise substitutions, but only eight different octahedra can be obtained. These give the eight cubes associated with the selected cube. The eight cubes having been determined, the problem of forming them admits of just two solutions. One solution is—



Selected Cube (transformed) diagonal 16 vertica



Lower Four Cubes.



Upper Four Cubes.

The other solution is obtained by interchanging clock-wise and counter clock-wise rotations of octahedral faces. Other interesting properties of these cubes are examined in the paper.

Geological Society, January 25.—W. H. Hudleston, F.R.S., President, in the chair.—The following communications were read: On inclusions of tertiary granite in the Gabbro of the Cuilin Hills, Skye; and on the products resulting from the partial fusion of the acid by the basic rock, by Prof. J. W. Judd, F.R.S.—Anthracite and bituminous coal-beds; an attempt to throw some light upon the manner in which anthracite was formed; or contributions towards the controversy regarding the formation of anthracite, by W. S. Gresley.

February 8.—W. H. Hudleston, F.R.S., President, in the chair.—The following communnications were read: Notes on some coast-sections at the Lizard. By Howard Fox and J. J. H. Teall, F.R.S. In the first part of the paper the authors describe a small portion of the west coast near Ogo Dour, where hornblende-schist and serpentine are exposed. As a result of the detailed mapping of the sloping face of the cliff, coupled with a microscopic examination of the rocks, they have arrived at the conclusion that the serpentine is part and parcel of the foliated series to which the hornblende-schists belong, and that the apparent evidences of intrusion of serpentine into schist in that district are consequences of the folding and faulting to which the rocks have been subjected since the banding was produced. The interlamination of serpentine and schist is described, and also the effects of folding and faulting. Basic dykes, cutting both serpentine and schists, are clearly represented in the portion of the coast which has been mapped, and these locally pass into hornblende-schists, which can, however, be clearly distinguished from the schists of the country. The origin of the foliation in the dykes is discussed. The second part of the paper deals with a small portion of the coast east of the Lion Rock, Kynance. Here a small portion of the "granulitic series" is seen in juxtaposition with serpentine. The phenomena appear to indicate that the granulitic complex was intruded into the serpentine; but they may possibly be due to the fact that the two sets of rocks have been folded together while the granulitic complex was in a plastic condition, or to the intrusion of the serpentine into the complex while the latter was plastic.—On a radiolarian chert from Mullion Island, by Howard Fox and J. J. H. Teall. The main mass of Mullion Island is composed of a fine-grained "greenstone," which shows a peculiar globular or ellipsoidal structure, due to the presence of numerous curvilinear joints. Flat surfaces of this rock, such as are exposed in many places at the base of the cliff, remind one somewhat of the appearance of a lava of the "pahoehoe" type. The stratified rocks, which form only a very small portion of the island, consist of cherts, shales, and limestone. They occur as thin strips or sheets, and sometimes as detached lenticles within the igneous mass. The chert occurs in bands varying from a quarter of an inch to several inches in thickness, and is of radiolarian origin. The radiolaria are often clearly recognisable on the weathered surfaces of some of the beads, and the reticulated nature of the test may be observed by simply placing a portion of the weathered surface under the microscope. The authors describe the relations between the sedimentary and igneous rocks, and suggest that the peculiar phenomena may be due either to the injection of igneous material between the layers of the stratified series near the surface of the sea-bed while deposition was going on, or possibly to the flow of a submarine lava. The form of the radiolaria observed in the deposit, and also their mode of preservation, are described in an appendix by Dr. G. J. Hinde.—The reading of these papers was followed by a discussion, in which the President, Rev. Edwin Hill, Prof. Bonney, Dr. Hicks, Dr. Hind, and the authors took part.—Note on a radiolarian rock from Fanny Bay, Port Darwin, Australia, by G. J. Hinde. A specimen brought from Fanny Bay by Captain Moore, of H.M.S. *Penguin*, is of a dull white or yellowish tint, in places stained red. It has an earthy aspect, and is somewhat harder than chalk, but gives no action with hydrochloric acid. Microscopic sections show a fairly transparent groundmass, apparently amorphous silica, containing granules and subangular fragments up to ·075 millim. in diameter, some of which appear to be quartz. Besides this, the rock contains numerous radiolaria, and it is really a radiolarian earth intermediate in character between the Barbados earth and such cherts as those of the Ordovician strata of Southern Scotland. The details of the extent of the deposit and its relationship to other rocks of the area are not yet obtainable, though it is possible that a considerable thickness of rock mentioned by Mr. Tenison Woods as occurring in this area may also be of radiolarian origin. The author describes a species of *Cenellipsis*, two of *Astrophacus*, one of *Lithocyclia* (new), one of *Amphibrachium*, three of *Spongodiscus* (one new), four of *Spongolena* (all new), two of *Dictyomitra* (both new), one of *Lithocampe* (new), and two of *Stichocapsa* (both new). From these it is not practicable at present to determine the geological horizon of the rock; with one exception, all the genera represented occur from Palæozoic times to the present.—Notes on the geology of the district west of Caermarthen. Compiled from the notes of the late T. Roberts (communicated by Prof. T. McKenny Hughes, F.R.S.). To the east of the district around Haverfordwest, formerly described by the author and another, an anticlinal is found extending towards Caermarthen. The lowest beds discovered in this anticline are the *Tetragraptus*-beds of Arenig age, which have not hitherto been detected south of the St. David's area. They have yielded eight forms of graptolite, which have been determined by Prof. Lapworth. The higher beds correspond with those previously noticed in the district to the west; they are, in ascending order: (1) Beds with "tuning-fork" *Didymograpti*, (2) Llandeilo limestone, (3) *Dicranograptus*-shales, (4) Robeston Wathen and Sholeshook limestones. Details of the geographical distribution of these and of their lithological and palæontological characters are given in the paper. After the reading of this paper Dr. Hicks said he felt sure he was expressing the feelings of the Fellows in referring to the serious loss which the Society had suffered by the death of Mr. T. Roberts, who certainly was one of the most promising palæontologists in this country. The important researches which he carried on, in conjunction with Mr. Marr, had made is now comparatively easy to understand some intricate and extensive districts in Pembrokeshire and Caermarthenshire, which previously were little more than blanks on the geological map.

February 17.—Anniversary Meeting.—The medals and funds were awarded as follows:—The Wollaston medal to Prof. N. S. Maskelyne, F.R.S.; Murchison medal to the Rev. O. Fisher; Lyell medal to Mr. E. T. Newton; and the Bigsby medal to Prof. W. J. Sollas, F.R.S.; the balance of the proceeds of the Wollaston fund to Mr. J. G. Goodchild; that of the Murchison fund to Mr. G. J. Williams; and that of the Lyell fund to Miss C. A. Raisin and Mr. A. N. Leeds. The following is the list of officers and council elected at the meeting:—President: W. H. Hudleston, F.R.S. Vice-Presidents: Sir A. Geikie, F.R.S., G. J. Hinde, Prof. J. W. Judd, F.R.S., H. Woodward, F.R.S. Secretaries: J. E. Marr, F.R.S., J. J. H. Teall, F.R.S. Foreign Secretary: J. W. Hulke, F.R.S. Treasurer: Prof. T. Wiltshire. Prof. J. F. Blake, Prof. T. G. Bonney, F.R.S., R. Etheridge, F.R.S., Sir A. Geikie, F.R.S., Prof. A. H. Green, F.R.S., Alfred Harker, H. Hicks, F.R.S., G. J. Hinde, T. V. Holmes, W. H. Hudleston, F.R.S., J. W. Hulke, F.R.S., Prof. J. W. Judd, F.R.S., R. Lydekker, Lieut.-General C. A. McMahon, J. E. Marr, F.R.S., H. W. Monckton, Clement Reid, F. Rutley, J. J. H. Teall, F.R.S., Prof. T. Wiltshire, Rev. H. H. Winwood, H. Woodward, F.R.S., H. B. Woodward. The presidential address dealt with some recent work of the Geological Society, the subjects ranging over a period of six or seven years. These embraced Pleistocene geology, theories in connection with Glaciation, Tertiary, Cretaceous, Jurassic, and Permo-Triassic geology. It further mentions that the number of papers on Pleistocene geology has been very considerable, and many of them relate to the south-east and the south of England; those relating to Central England and South Wales were fewer in number, whilst the north had furnished but few papers. The great memoir on the Westleton Beds had provided much material for consideration; that portion relating to the Southern Drift being especially interesting. Reference was made to a paper on Pleistocene succession in the Trent basin as forming a fitting introduction to the fascinating problems connected with the North Wales border on the one side and with Flamborough Head on the other. From Scotland notice was taken of some supplementary remarks on the paralled roads of Glen Roy. Speculation as to the evidence of a palæozoic ice age, the date and duration of the Pleistocene glacial period, and a notice on misconceptions regarding the evidence of former glacial periods were also discussed. The Tertiary Geology of the London and Hampshire basins was considered, more especially in relation to the Upper Eocene, or Bartons, and their probable equivalents in West Surrey. Under this heading, also, comes the Geology of Barbados, since the oceanic deposits in that island were held to be of late Tertiary age. These interesting discoveries were reviewed at some length, and the results compared with tables in the recently issued "*Challenger* Reports." In Upper Cretaceous Geology the phosphatic deposits at Ciply and Taplow were noticed, and also the important correlations of the basement-beds in Norfolk, Lincolnshire, and East Yorkshire. The Lower Cretaceous beds at Speeton next passed under review, more especially in connection with their somewhat difficult palæontology and possible equivalents in Eastern Europe. It then went on to state that our knowledge of the Upper Jurassics of the East of England had of late years received considerable additions and important correlations between our Upper Jurassics generally, and their equivalent on the Jura had been effected, that the inferior Oolite and the Lias boundary had come in for their share of attention, whilst a determined attempt had been made to refer a portion of the red rocks of South Devon to the Permian.

PARIS.

Academy of Sciences, February 13.—M. de Lacaze-Duthiers in the chair.—On an invariant number in the theory of algebraic surfaces, by M. Émile Picard.—Study of the Cañon Diablo meteorite, by M. Henri Moissan. The composition of the meteorite is very variable from point to point. In the fragments examined the percentage of iron varied from 91·09 to 95·06, and that of nickel from 1·08 to 7·05. Diamonds were also found, both transparent and black, and a brown form of carbon of feeble density. The largest diamond measured 0·7 mm. by 0·3 mm. It had a yellow tint and a rough surface, and was transparent to light.—On the meteoric iron of Cañon Diablo, by M. C. Friedel. A small quantity of a silver-white fragile compound occurring in the meteorite in the form of plates disseminated through the nickeliferous iron and accompanied by schreibersite, was isolated, and its composition found to correspond to the probable formula Fe_5S. The mixtures of ordinary carbon, graphite, and diamond were found chiefly associated with nodules of yellow troilite.—On the presence of graphite, carbonado, and microscopic diamonds in the blue earth of the Cape, by M. Henri Moissan. After repeated and lengthy treatment with boiling sulphuric and hydrofluoric acids, 250 gr. of blue earth left a residue weighing only 0·094 mgr. In this residue brilliant hexagonal crystals of graphite were found, giving rise, when treated with potassium chlorate, to a graphitic oxide of a colour passing from green to yellow. Another species of graphite was also isolated which, when treated with H_2SO_4 at 200° C., swelled up considerably and dissolved. Its artificial preparation will be described in a subsequent paper. The portions of the residue unaffected by potassium chlorate and heavier than methylene iodide (density 3·4) comprised an amber-coloured mass, black diamonds, microscopic true diamonds, and small transparent crystals in form of elongated prisms, which did not burn in oxygen and were not fluorescent in violet light. The first, which contains a large proportion of iron, and the last, which contains silica, can be destroyed by treatment with fused potassium bisulphate and then with hydrofluoric and sulphuric acids. The blue earth, which was taken from the Old de Beers Mine, thus contained all the carbon compounds found in the iron matrix employed for their artificial production.—The clasmatocytes, the fixed cellules of the connective tissue, and the pus globules, by M. L. Ranvier. In an inflamed tissue the clasmatocytes and leucocytes are the only ones which give rise to purulent globules, the latter being, in fact, mortified lymphatic cellules.—Glycosic expenditure attendant upon nutritive movement in hyperglycemia and hypoglycemia brought about experimentally; consequences bearing upon the immediate cause of diabetes and other deviations of glycemic function, by MM. A. Chauveau and Kaufmann.—Observations of Holmes's comet made with the *equatorial coudé* (0·32 m.) of the Lyon Observatory, by M. G. Le Cadet.—On an explicit form of the addition formulæ of the most general hyperelliptic functions, by M. F. de Salvert.—On the laws of reciprocity and the sub-groups of the arithmetical group, by M. X. Stouff.—Experiments on overflowed weirs, by M. H. Bazin.—On the fringes of caustics, by M. J. Macé de Lépinay.—On a phenomenon of apparent reflection at the surface of the clouds, by M. C. Maltézos.—On the electric figures produced at the surface of crystallised bodies, by M. Paul Jannetaz. If the face of a crystal be covered with matter consisting of light and small grains, such as lycopodium seed or talc powder, and an electric discharge passed into the face through a point outside it, certain figures are formed, many of which were investigated by Wiedemann and Senarmont. Very regular ellipses were obtained by M. Jannetaz by passing a series of discharges from an electrostatic machine or an induction coil. The orientation of the major axes of the ellipses was observed for a large number of minerals. In most cases this axis was perpendicular to the direction of maximum conductivity for heat. In the case of a well-defined single cleavage, such as that of mica, talc, a block of wood, the cut edge of a book, or a schistose rock, the major axis was perpendicular to the plane of cleavage. The point need not touch the plate. Figures were obtained on a plate of gypsum strewn with lycopodium powder, and charged from beneath. Positive and negative sparks show the same effect.—Action of temperature on the rotatory power of liquids, by M. Albert Colson.—Density of nitrogen dioxide, by M. A. Leduc.—Considerations on the genesis of the diamond, by M. J. Werth.—On the chlorine derivatives of the propylamines, the benzylamines, aniline and paratoluidine, by M. A. Berg.—On dipropylcyanamide and dipropylcarbodiimide, by M. F. Chancel.—Survival after section of the two vagi nerves, by M. C. Vanlair.—On the internal pericycle, by M. Léon Flot.—On a modification to be applied to the construction of bottles designed to collect specimens of deep waters, by M. J. Thoulet. The compressibility of water is such that one litre, collected at a depth of 8000 m. below sea-level, would expand by 35 cc. when the bottle was opened at the surface. Such bottles may therefore be constructed of thin sheet copper or other metal allowing an expansion of thirty-five parts in 10,000.—Lines of structure in the Winnebago County meteorite and some others, by Mr. H. A. Newton.—On a meteorite observed at Newhaven (Connecticut), by Mr. H. A. Newton.

THURSDAY, MARCH 2, 1893.

MODERN OPTICS AND THE MICROSCOPE.

The Microscope: its Construction and Management. Including Technique, Photomicrography, and the past and future of the Microscope. By Dr. Henri van Heurck, &c. English edition re-edited and augmented by the author from the fourth French edition, and translated by Wynne E. Baxter, F.R.M.S., F.G.S. (London: Crosby Lockwood and Son, 1893.)

THIS is a handsome, even a luxurious, book. It is beautifully printed on highly-finished paper, and with a margin ample enough to satisfy the most exacting connoisseur. The illustrations are clearly produced, the binding is admirable, and after a careful comparison with the last French edition, we do not hesitate to say that the translation is as felicitous as it is accurate.

Its author has aimed apparently at an elementary treatise on the microscope, which is nevertheless intended to cover almost the entire field involved in its history, production, and use. The difficulties of such a task are not a few. To be elementary and thoroughly popular up to a limit, very sharply defined, and then to lead on those who choose to follow into the deeper aspects of this many-sided subject, is at once practical and natural. The optics of the modern microscope are the possession of the specialist. Abbe himself has failed to make them accessible to and understanded by any but those educationally equipped. Hence the constant misunderstanding of the fundamental principles of the Diffraction Theory and its related applications so frequently manifest even where the subject is supposed to be more or less familiar.

As might have been readily supposed, the author of this treatise has given evidence of skill in the presentation of the main points of elementary optics; it is, however, clearness and conciseness, not originality, that is to be noticed. The illustrations are those familiar to English text-books for the last quarter of a century, and the diffraction theory has in no way been simplified to the reader of an elementary treatise by that most efficient of all elementary modes of imparting ideas on more or less abstruse subjects, viz. carefully devised and well-explained diagrams.

Considering the object of this treatise, viz. the impartation of knowledge to those not mathematically prepared to follow it in that direction, by giving a concise, clear, and comprehensive view of the meaning and application of the diffraction theory of microscopic vision, the transition from the first to the second chapter will be so abrupt and unlinked as to leave the elementary reader practically in the dark. The chapter on "The Theory of Microscopic Vision" is unexceptional so far as it goes. It cannot be other, it is Prof. Abbe's; but in a treatise claiming to maintain its elementary character more completely than any other similar work which covers so wide a range this is surely not enough.

The diffraction theory of vision is introduced to the tyro with no explanation of what diffraction is, and with no illustration of its action until he is plunged *in medias res* in Abbe's application of it to the profoundly important and inestimably valuable theory itself. The "elementary" character of this is at least questionable. Beyond this that most important factor in the diffraction theory in its practical application, Numerical Aperture, is wholly without explanation, save such as arises from its technical introduction and employment; but there are few points on which it is more important that an elementary student should be more clearly instructed, and there are few that lend themselves more to efficient diagrammatic presentation. In the same relation it may be noted that the very essential formula n sin u—expressing the general relation discovered by Abbe between the pencil of light admitted into the front of the objective, and that emerging from the back lens of the same, which is such that the ratio of the semi-diameter of the emergent pencil to the focal length of the objective could be expressed by the sine of half the angle of aperture (u) multiplied by the refractive index of the medium (n) in front of the objective or n sin. u—but this is a German mathematical formula; and its English equivalent is μ sin. ϕ, and although the German form of symbol is employed in England, and thoroughly understood by mathematicians, those who are entering for the first time upon a study of this difficult subject, and therefore unaccustomed to the mathematical formulæ employed, might readily fall into confusion, seeing that the "elementary" source of their information leaves them without a hint on the subject.

Another serious defect, as we believe, in this "elementary" presentation of the diffraction theory of microscopic vision is the absence of an easy explanation of the *photometrical* equivalent of different apertures. Certainly it is not of the essence of the problem, but it is just one of those points which in a very marked and instructive manner illustrate the meaning and value of numerical aperture as such; and for elementary exposition this must be of importance. Thus, if two circles be taken to represent the backs of two objectives of the same power but of different apertures, and the radius of one be twice that of the other, then each radius will represent the angle n sin. u. But because the areas of these circles are to each other in the proportion of the squares of their radii, it follows that if each radius be designated by n sin. u, the area of the lesser circle will be to the area of the greater circle as the square of the radius of the former is to the square of the radius of the latter. Hence the area of the greater circle will be four times as great as that of the lesser, which teaches that since the numerical aperture of one objective is twice as great as that of another its illuminating power will be *four times* as great—a most important incidental and explanatory *raison d'être* for great N. A.

In this connection we notice what is certainly not easily explicable as an exposition of the details of Abbe's great theory. On page 56 of "The Microscope" Dr. Van Heurck almost incidentally states the very important fact that "Prof. Abbe has satisfactorily established the fact that a certain relation must exist between magnification and angular (?) aperture." This is undoubtedly one of the most important demonstrations of the theory. Great numerical apertures have proved of untold value to the competent student of minute details, by opening up structures that mere amplification must have left for ever impenetrable. But that does not annul the importance of small apertures. Low amplifications are as useful in their own department as high ones; and to put great apertures to lower magnifying powers than such magnifying power warrants is to sin against the elementary principles of the Abbe theory of vision. And on the other hand, wide apertures can never be utilised unless there is a concurrent and suitable linear amplification of the image which is competent to exhibit to the eye the smallest dimensions which are by optical law within the reach of such apertures.

Thus it follows that great amplification will be useless with small apertures. If the power be deficient the aperture will not avail; if the aperture be wanting nothing is gained by high power. The law is, "Employ the full aperture suitable to the power used." In Abbe's words, "A proper economy of aperture is of equal importance with economy of power." [1]

Taking these facts, then, which are apparently recognised by Dr. Van Heurck, it is very remarkable to find on page 49, in a discussion of the "screw threads" or gauges employed by the makers of microscopes, that the general value of the English gauge is admitted, but it is added, "The English thread is not, however, all that we have to say on this matter. In America the *American thread* is also employed, which is considerably greater, and admits the use of lenses with a much larger diameter, *and thus offers certain advantages*. In the first place, the larger the lens the easier it is to make, and consequently the real curvatures approach closer to the calculated curvatures; then the larger the lens the more luminous rays it admits, and this in photography is not to be despised."

To our judgment this statement is a contradiction of the admission made on page 49, quoted above.

The enlargement of the screw for the purpose of putting in larger back lenses to objective combinations was first mooted in America in 1879,[2] when "Mr. Bullock urged the desirability of adopting a uniform objective screw of larger size than the Society screw now in use (1879), as being essential to the efficacy of *low power lenses of high angle*."

This "American gauge" was subsequently introduced and known as the "Butterfield gauge of screw for objectives." [3]

Now, we must remember the date of the introduction of this large gauge for objectives, and its relation to the introduction of the apochromatic system of lenses. We must further remember that the purpose of its adoption was to permit the introduction of larger back lenses than the Society gauge would suffer into an objective combination. This meant giving relatively great apertures to lower powers. But this, carried beyond a certain limit, violated a fundamental law of Abbe's theory.[4] Now it is said that these larger lenses are easier to make (!) and approach more nearly to the calculated curves. But in truth objectives with wide apertures which are low powers, and must therefore have large backs, are most difficult lenses to produce. It was, in fact, to escape the difficulty of giving lower powers larger angles that opticians of the first rank always designated their objectives as of lower magnifying power than they really were. They in fact made a $\frac{2}{3}$rds a $\frac{1}{2}$; a $\frac{1}{2}$ a $\frac{4}{10}$ths; a $\frac{4}{10}$ths a $\frac{1}{4}$; a $\frac{1}{4}$ a $\frac{1}{6}$; and so on.

Since Butterfield's gauge was introduced, long before the days of apochromatism, that is when our ignorance allowed us to over-aperture our low magnifying powers, it was tolerable, because it was evidence of experimental effort to improve the capacity of our lenses. But to-day *with* the society screw we are easily provided with a series beginning with a 1 inch objective of ·3, and a $\frac{1}{2}$ inch objective of ·65 N.A., and we may venture to think that these are the highest ratios of aperture to power that will be accomplished for many a day; and therefore the highest ratios allowable by the Abbe theory of vision, which we now know, at least in this point, to be an enunciation of the established laws of optics.

Moreover, *these* lenses are really difficult to make, with their back lenses easily placed within the diameter of the Society screw. A high ratio of aperture to power always involves great expense in production; and therefore we find that the *low-priced* oil immersions of this immediate time are $\frac{1}{12}$ths and $\frac{1}{8}$ths, not objectives of low magnifying power, and for this reason only.

Since then the Society screw is sufficient for more than double the apertures shown by Abbe to be in suitable ratio to the lower powers, we find it more than difficult to account for the teaching in a treatise intended to be essentially elementary, that the Butterfield screw gauge for objectives provides conditions which "offer certain advantages," when the supreme object of this part of the book is to enunciate fully the nature and qualities of oil immersion achromatic, and especially apochromatic, object glasses, by which we can get larger apertures with the society screw than in the old days of Butterfield's gauge could be got by the use of abnormal backs to objectives. We find also that "penetrating power" is referred to in passing as one of the properties of object glasses (p. 56); but since the diffraction theory of microscopic vision is associated with a special interpretation of what this means, and since it is to Prof. Abbe that we are indebted for placing this hitherto obscure matter on a sound, scientific basis, it somewhat disappoints the reader to find no allusion whatever to the valuable work done on this subject, nor any elementary endeavour to explain the great truth that the actual depth of vision must always be the exact sum of the accommodation depth of the eye and the focal depth of the objective. But there are few matters of more practical importance or that lend themselves more to simple exposition.

In a treatise purporting to be essentially for the beginner we confess to disappointment concerning the instructions as to the "choice of a microscope." What is needed is that the tyro should know the *essentials* of the instrument; the points in it that are of indispensable importance, and a clear account of the manner in which these may—by the uninitiated—be seen to be of inferior or acceptable workmanship. The reader is not even informed that in so important a matter as the *fine adjustment* there is a different value to be attached to several entirely different methods by which this function of the microscope is performed. The bar and lever movement, essentially the best in principle and practice, is only referred to as existing, in the index, which is thus made to serve as a kind of glossary; and even more remarkable is the fact that the patent lever fine adjustment of Swift and Son, the only fine adjustment which, in our judgment, makes the "Jackson Model" microscope (which Dr. Van Heurck evidently affects) at all a practicable instrument, is treated in the same way. So indeed is Campbell's differential screw; and the highest commendation is given to the form adopted in the author's own model. No doubt in its present form it is relieved of many defects incident to the form of fine adjustment to which it belongs; but it must be remembered that we are told that each of the divisions of the milled head of this fine adjustment corresponds to the $\frac{1}{1300}$th of a millimetre. Yet the screw which gives this fine result has to lift the whole "body" of the instrument. In the lever fine adjustments only a nose-piece is lifted, having an inconsiderable weight, and producing in practice no friction, and to this the objective is attached; it certainly appears but reasonable, as it has proved in practice to workers who have employed the several methods for continuous years, that the "wear and tear" upon so fine a screw to which such heavy work is given does not contribute to permanent steadiness, or in constant work, to continued accuracy.

[2] *American Naturalist*, vol. xiii. p. 60.

[3] J. R. M. S., ser. ii. vol i. p. 301.

[4] *Ibid.*, vol. ii. p. 204.

In fact, after careful study of the microscope specialised in this treatise, it is difficult to discover anything really new or distinctive in it save the bringing of the fine adjustment pinion of the sub-stage above the level of the principal stage. The value of this may be variously assessed, but it has the plain disadvantage of preventing the complete rotation of the principal stage; and it may be doubted if it has any advantage which will compensate for this.

There is little, if anything, to enable the reader to distinguish as to the practical value of one form of stand as compared with another, and yet there can be no greater divergence in form than that between the Continental stand on the one hand with its dead weight to produce steadiness, and the two English models known as the Ross and Jackson models respectively on the other. What distinguishes them, in what either of them has superiority over the other, and wherein in any of them what is essential to a first-rate working microscope, is nowhere discussed.

It is true that the models of many makers are presented and beautifully printed; but many of these are not printed in these pages as revealing essential differences important for the reader to observe, but they are placed amongst others simply as the productions, with slight variations, of the same instruments by different makers. We cannot but believe that if some plain directions had been given as to the essentials of a good microscope, and the principal models passed in review showing their conformity or otherwise to these requirements, the "elementary" object of the book would have been more fully accomplished, and the tyro more fully aided in the "choice of a microscope."

Dr. Van Heurck has shown his practical knowledge of the microscope as a manipulator in many ways, in this book, but perhaps this is nowhere more fully seen than in his full appreciation of the *condenser* as an indispensable instrument in bringing out the finest optical possibilities of the most perfectly constructed object glasses. His book may be said to be alone amongst continental treatises on the microscope in this respect. It has been by very tardy steps that the continental makers, or the continental microscopists, have learned to appreciate the immense importance of a condenser in causing optical combinations to give their highest results. It is but recently that so leading a firm as Zeiss has yielded on this point and produced condensers. The first was chromatic, and, as a consequence, proportionately unsatisfactory. Then came the most useful achromatic form of Abbe. But we are glad to observe that Van Heurck recognises that the *apochromatic* immersion condenser of Powell "is the most perfect condenser which exists at present" (p. 85). It is inevitable that with apochromatic objectives it should be. We cannot possibly see how the splendid objectives on apochromatic principles can give their finest results unless they are illuminated by an apparatus which is not only as perfect in workmanship, but of as great a numerical aperture, and with as complete corrections as the objective which is collecting the light and forming the image of the object the condenser is illuminating.

And for this reason, while we admit fully that the plate of photo-micrographs produced in this and other volumes by the very exceptional skill of Dr. Van Heurck with the most remarkable object glass which the manipulative skill of man has yet produced, viz. the 2·5 mm. with N.A. 1·63, is a monument to his manipulative ability, we still contend that he worked under difficulties of no small importance. The only condenser provided for this lens by the great firm which produce it, is one which of necessity has a flint front, but is as wholly uncorrected as the glasses used by Hooke or Bonanni!

Now if it be important to use an apochromatic condenser at all, how much more important to use it on such a lens, with such an aperture and such exquisitely refined corrections. This objective has never yet had its best power revealed, because its illumination has been always a counteraction of its own refinements.

We are surprised that in manipulation the tyro is recommended in this treatise to focus *down* upon the object first, of course with great care, and then to find the actual focal point by withdrawing the tube by either coarse or fine adjustment. A far more elegant and safe method is certainly adopted, and we doubt the preference expressed for daylight as the best constant source of illumination. It is uncertain and always variable and more refractory than the edge of a good lamp-flame, unless we need a monochromatic ray from a sunbeam.

At the close of the book there is a communication which had appeared before in the Journ. Roy. Micro. Soc., from Dr. S. Czapski, which gives a suggestion for the possible enlargement of the practical N.A. of homogeneous object-glasses, which makes an advance to 2·0 possible without the employment of the dense flint and highly refractive media needed by the lens spoken of above. In fact it is plain that true monochromatic light may increase a N.A. of 1·40 to 1·75.

There is a chapter on photomicrography which has the value that is inevitable, coming as it does from one of the most practised and efficient workers; still it can hardly be expected to be exhaustive, and every practical photomicrographer has, and adopts as most perfect, his own methods; and as none will ever become photomicrographers who have not some ingenuity and enthusiasm, it is only needful that they be set to work, and they will undoubtedly find *their own* "best methods."

This treatise is too general to expect from it more than useful and suggestive hints on the subject of the preparation and mounting of objects; and the same may be said as to the history of the microscope, which is nevertheless given in an interesting and useful manner. The book will undoubtedly attract many readers, and it will afford help to many who are seeking it; but we respectfully doubt whether it will enable the elementary reader to fully follow the diffraction theory of microscopic vision, so as to be able to understand its application to the wide range of subjects supposed to be dealt with from that point of view by this sumptuous treatise.

W. H. DALLINGER.

A UNIVERSITY EXTENSION MANUAL.

The Earth's History: an Introduction to Modern Geology. By R. D. Roberts, M.A. (Camb.), D.Sc. (Lond.). With Coloured Maps and Illustrations. (London: John Murray, 1893.)

THIS is not a large book, and a slightly less ambitious title might have been more appropriate. Certainly it is an introduction to the study of modern geology rather than a history of the earth, for the latter is regarded from a limited point of view. But from the page preceding the frontispiece it appears that the volume is one of a series of "University Extension Manuals." It partakes, therefore, of the advantages and disadvantages of this method of disseminating knowledge.

The topics treated by Dr. Roberts are the progress of geological thought: the beginnings of the earth's history: the modifications of its surface due to forces destructive and reproductive: the movements of its crust, including the action of volcanoes. Finally he deals with the formation of rock masses, and attempts to give—though of necessity this subject is very imperfectly treated—some idea of the evolution of the British Islands.

The materials employed by the author are not generally novel, for one text-book must draw from much the same storehouse as another, but Dr. Roberts has a lucid and pleasant method of statement, gained no doubt by his experience in the lecture room. One point, however, though it relates to a well-worn subject, will be fresh to most readers. In speaking of the submergence of the so-called Temple of Serápis at Puzzuoli, Dr. Roberts cites a passage from the Acts of Peter and Paul, an apocryphal booklet, to which attention was drawn a few months since by Mr. Thomson (*Geol. Mag.*, 1892, p. 282). This states that Pontioli (Puteoli, now Puzzuoli) was submerged as a punishment for the martyrdom of Dioscurus. "They all see that city Pontioli sunk into the sea-shore about one fathom, and there it is unto this day for a remembrance under the sea." On which passage Dr. Roberts observes that when the Acts was written, "Puzzuoli was under water, and had been so for so long a time that the memory of the actual events had been lost and replaced by the tradition recorded in the Acts." At first sight this, as he says, seems in favour of the submergence having occurred "between the third and fifth centuries, and probably earlier than the fourth."

This passage certainly makes it probable that the submergence began at a rather early time, but it is no easy matter to fix the date of any passage in these Acts. Parts of the book are believed to be as old as the second century, while others are not earlier than the fifth century. The book, also, was not of Western but of Eastern origin. Had the book been written in Italy then, notwithstanding its other absurdities, some weight might be attached to a topographical reference; but these, as it was compiled at a distance, and by obviously ignorant people, seriously impair its credit. It is also needful to show that this story forms part of the later recensions and is not merely founded on some vague tradition of change of level in the neighbourhood. In any case, Dr. Roberts seems to go a little too far in saying "this would allow about ten centuries, during which the marble columns were under water exposed to the action of the living molluscs." Hardly so; this tradition at most would not take us beyond the first submergence, that indicated by the brackish water deposit at the base of the pillars. Over this came an irregular mass of volcanic ash, which was covered by a calcareous tufa, in places full four feet thick. The former, of course, may have accumulated in a few hours, but the latter must indicate a considerable time. The temple, also, must have been in complete ruin before the showers of ashes fell—which also would require time. So that Dr. Roberts perhaps would have done better to have adhered to the more cautious statement in Mr. Thomson's letter, and not claimed quite so long a period for the maximum submergence.

Within the limits, which the necessities of the case impose, the book is well conceived and well executed: though we cannot help doubting the wisdom of encouraging, by manuals necessarily partial and incomplete, students to imagine that they have really mastered a subject; at any rate, it should be frankly admitted that this, however useful and interesting, is not education.

OUR BOOK SHELF.

The Health Officer's Pocket-Book. By E. F. Willoughby, M.D., D.P.H. (London: Crosby Lockwood and Son, 1893.)

THIS is a work the object of which is to provide a portable and well-bound book of reference, to which the health officer may turn at any moment for most of the facts, formulæ, and data required in his daily practice; and while one cannot give unqualified assent to Dr. Willoughby's contention that such a book is indispensable, one is prepared to acknowledge that it may prove to be useful. It is not easy, however, to conceive the conditions under which a health officer is called upon to take action or to give advice, at a moment's notice, upon points so remote from the routine practice of his duties that he will ever find it necessary to carry about, for consultation, a pocket-book of abstruse sanitary facts and formulæ and legal enactments. If such a work is indispensable, the author would have done well to restrict its bulkiness somewhat, and more especially since he could have achieved this by the omission of a great deal of matter which is, on the face of it, foreign to the purpose of the book. To instance such:—The parts which nitrogenous and non-nitrogenous food stuffs play in the animal economy; the origin and nature of cyclones; a quantity of discursive material upon vital statistics; and a host of elementary hygienic facts with which every sanitarian is conversant,—are none of them points it can ever be necessary for the health officer to carry about with him for hasty reference.

The most useful sections, and those which most justify the *motif* of the book, are the following:—Those which deal with mathematical problems, and set forth useful algebraical and trigonometrical formulæ, together with a few logarithm tables; that upon demography and vital statistics; and the serviceable abstract of sanitary law, in which corresponding or similar sections of the Public Health Act, 1875, and the Public Health (London) Act, 1891, are considered side by side.

There is very little in the book which is not correct and up to date, save that which refers to the subject of water analysis. This contains many errors, and, since the utility of its introduction is very questionable, it is regretable that it mars the all-round accuracy of the work. In this section Dr. Willoughby gives several results of his own analyses, and those who are familiar with the subject will find their experiences much at variance with the writer's.

In what he calls a typical sample of *rain-water* he found 0·63 grains per gallon of nitrates as HNO_3, and 0·114 and 0·172 parts per million of "ammonia" and "albuminoid ammonia" respectively; in *river-water* at Latchford he found no nitrates, not even a fraction of a part per million, and the "ammonia" and "albuminoid-ammonia" were 0·08 and 0·16 (parts per million) respectively. Loch Katrine water is, moreover, credited (and Wanklyn is quoted as the authority) with 0·008 parts per million of "albuminoid-ammonia," and with 0·004 of "ammonia;" and the former is said to correspond to 0·0056 grains per gallon!

While unquestionably the work contains some material which will make it useful to the health-officer, the health student will find much in it which he may peruse with advantage.

Engler's Botanische Jahrbücher für Systematik, Pflanzengeschichte und Pflanzengeographie. (Leipzig: W. Engelmann.)

SINCE Dr. A. Engler's appointment to the post of Director of the Berlin Botanical Garden and Museum, this periodical has become the organ of the very active staff of botanists of that establishment; and the comparatively recent German colonial policy has revived the interest in systematic and economic botany, to which it is devoted chiefly. Vols. xv. and xvi. are being published concurrently. This publication is partly devoted to original work and partly to a review of contemporary botanical literature. The fifteenth volume is largely taken up by contributions to the flora of tropical Africa, in the form of an elaboration by various botanists of the extensive collections made by numerous German travellers. Quite a host of new species are described, but, truth to say, nothing very remarkable in new generic types. *Hybophrynium* is a new genus of Scitamineæ, near *Trachyphrynium*, with which it was generically associated by Bentham and Hooker; and the Aroideæ, elaborated by Engler himself, include two or three new genera. *Pseudohydrosme* is characterised by a large, almost truncate spathe and a spadix without any terminal naked continuation.

Dr. J. Urban, who has been for some years engaged in collecting materials for a general flora of the West Indies, contributes "Additamenta ad Cognitionem Floræ Indiæ Occidentalis," a critical work, both from a botanical and a literary standpoint. No new genera are described.

One of the most interesting articles in the sixteenth volume is by Dr. O. Warburg, on the mountain plants of Kaiser Wilhelm's-Land, New Guinea. The collection of plants dealt with consisted of only fifty-three species, whereof thirty-two were supposed to be endemic, though the material of a few was insufficient for description. Two new genera are described, namely, *Hellwigia pulchra*, a pretty scitamineous plant, and *Zoelleria*, a singular boragineous plant, described as having ten nutlets in the place of the usual four! Among the new species are five rhododendrons, and the most noteworthy feature of the collection was the absence of essentially Australian types.

Another paper of general interest is Dr. Kränzlin's "Beiträge zu einer Monographie der Gattung Habenaria," excluding *Platanthera*, united with *Habenaria* by some botanists, 347 species are described; and they are spread over nearly the whole area inhabited by orchids.

Dr. Carl Bolle's "Botanische Rückblicke auf die Inseln Lanzarote und Fuertaventura" is a pleasantly written essay on the indigenous and cultivated plants of these islands. The "Jahrbücher" contain many other valuable articles. W. B. H.

Descriptive Geometry Models for the use of Students in Schools and Colleges. Designed by T. Jones, M.I.M.E. (Moss Side, Manchester.)

THE models are six in number. They are intended to show a line (1) by its projections, (2) by its traces; the inclination of an oblique plane (3) to the vertical plane, (4) to the horizontal plane; and to determine the angle (5) between two intersecting lines (6) between two planes. They are accompanied by hints for fixing and studying the models, and with a useful list of problems suggested as exercises for students. The clearness of the explanations, the simplicity of the constructive apparatus, and the compactness of the arrangements (all being contained in a handy cardboard box) commend Mr. Jones's work to students of solid geometry.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Lion-Tiger Hybrids.

I HAVE read Dr. Ball's account of this subject in the issue of NATURE for February 23, 1893, and beg leave to call attention to the fact that the University of Cambridge possesses the skeleton and the stuffed skin of an *adult* hybrid between a lion and a tigress. I am able to supply the following information (which I have verified so far as it was possible) with regard to this specimen from a contemporary MS., entitled "Notice of the Lion-tiger which died in Cambridge, March 1833," by J. B. Melson, then an Undergraduate at Trinity College. This MS. no doubt contains the substance of a paper by Mr. Melson, which was communicated by Dr. Haviland to the Cambridge Philosophical Society, May 6, 1833. The paper was unfortunately not printed in the Transactions of the Society.

The Cambridge specimen, like those mentioned by Dr. Ball, was procured from the menagerie of Mr. Atkins. It was about six years old, and for some time previous to its death had been affected with paralysis of its hind quarters, arising probably from a distortion of the lower thoracic region of the vertebral column [which is still a marked feature of the actual skeleton]. Although inferior in size to either of its parents, the animal appeared to have attained its full dimensions. The shape of the head resembled that of the father (the lion), whilst the form of the body was more similar to that of the tigress. The body was faintly striped, while the prevailing shade was "of a dingy lion colour." The animal had neither a mane nor a tuft at the end of its tail.

The specimen was a female, and Mr. Melson states that "all the individuals of this hybrid race have as yet been females." The orifice of the vagina was smaller than in the tigress; and the uterus was "merely rudimentary and nothing more than a membranous tube terminating in the two fallopian tubes." The ovaries were normal in appearance, though very much smaller than those of the full-grown lioness or tigress.

The extreme length of the skull, from the end of the occipital crest to the end of the præmaxillæ, of the specimen now in the Cambridge Museum, is 290 mm.; the distance between the foramen magnum and the end of the præmaxillæ is 235 mm.; and the extreme zygomatic breadth is 190 mm. The ascending process of the maxilla ends at a point 3 mm. in front of the posterior end of the nasal bones, and has a somewhat rounded termination. In these characters the skull of the hybrid resembles that of the lion much more closely than that of the tiger.

Travelling of Roots.

The mode in which roots travel in pursuit of food (moisture) is often remarkable. Innumerable instances have been published. But I think the inclosed is one of the most striking which I have come across. The specimen kindly sent to the Kew Museum by the vicar of Petersham is most extraordinary. The roots seem to have behaved more like the mycelium of a fungus than an ordinary axial structure.

W. T. Thiselton-Dyer.

Royal Gardens, Kew, Feb. 24.

Memorandum by the Rev. W. H. Oxley, Vicar of Petersham, dated February 16, 1893.

Roots of a Wistaria from the dining-room of Eden House, Ham, just demolished.

The root entered the room by a very small chink in the side of the window, near the ceiling, and on removing the paper, which had not been disturbed for many years, from the walls (of the room about 14ft. square) the whole of the plaster beneath the paper was found covered with a fine network of roots spreading all round the room. The specimen is about one-third of the whole roots and the stem where it entered the room. There was not the faintest appearance of anything of the sort on the surface of the wall paper to give rise to the suspicion of these roots being there, and the room was continually inhabited, with fires, &c.

The Flight of Birds.

With reference to an extract from *Science* on the flight of birds, which appeared in your "Notes" of February 16, I agree with the writer of that extract that the rapidity with which the generality of birds travel is often considerably over-estimated.

Some few months ago, whilst crossing, by G.W.R. express, the moors of Bridgewater Level in Somerset, a couple of turtle-doves rose at a distance of about eighty yards from the train, and flew for a considerable distance in a line nearly parallel with the rails.

I observed them with much interest, for I wished to have some comparison of their power of flight with that of some "homing" pigeons in my possession, and perceived that they were being slowly overtaken. They must have flown fairly parallel with the line of rails for at least 500 yards, and finally bore away northward. We must have been travelling at about forty miles an hour at the time, so that their speed would have been a little less than that. I was the more surprised at this as I had had "homing" pigeons, trained by myself, which, on a clear, calm day, had flown from the Quantock Hills to Taunton (a distance of seven miles) in less than eight minutes—a quite superior rate of flight, which, however, I do not think they would continue for a long distance. The Columbacei generally may be considered good flyers; the turtle, however, I believe from observation to be somewhat below the average standard of excellence. It certainly cannot be compared with the Passenger Pigeon of America, which has frequently been killed in the neighbourhood of New York with Carolina rice still undigested in its crop—having probably accomplished a journey of between 300 and 400 miles in about six hours, giving the high record of sixty miles an hour for six hours in succession. My own impression is that there is a great difference in the speeds of various orders and tribes of birds. I have repeatedly observed the fieldfare, which is a fairly strong flyer, overtaken by trains of which I have been an occupant, and which could not have been travelling more than forty miles an hour. On the other hand, I have witnessed the pursuit of a wood-pigeon or cushat by a hawk, in which both birds exhibited powers of flight which might seem incredible to persons unobservant of nature. In this instance I should have estimated the speed of the pigeon, which was straining every muscle to reach the shelter of a belt of timber, to be about sixty miles an hour; whilst that of the hawk, which flew with little effort, could not I think have been less than eighty, during the brief period that they were within my sight. I should be glad to hear from any of your correspondents their opinion as to the rapidity of flight in the Raptores (British).

Herbert Withington.

Taunton, February 22.

The Niagara Spray Clouds.

I do not remember having seen anywhere a reference to the fact that the spray clouds of Niagara exhibit an ice bow in clear frosty weather.

I had an opportunity last week of seeing a very fine complete bow, the inner one, the outer being absent.

There was no trace of the mock suns or of the bands of white light usually present; though I have seen ice bows without the latter, I have never seen one before without any trace of mock suns; these are generally accounted for by supposing the presence of hexagonal ice prisms. I would suggest the inference that the ice crystals in the Niagara spray clouds are not prisms but rhombs.

McGill University, Montreal, February 6.

British New Guinea.

In Nature (vol. xlvii. p. 345) Mr. H. O. Forbes has a lenient review of Mr. J. P. Thomson's "British New Guinea," in which he reproduces a figure of four natives. In the original they are called "native mountaineers" (p. 95). As a matter of fact only the two central men are mountaineers; the two outermost being coast natives who acted as decoys to induce the timid highlanders to submit to being photographed. Mr. Thomson has a reprehensible habit of inserting figures which, while they illustrate the contiguous text, really belong to a different part of British New Guinea than that there dealt with. I fancy Mr. Forbes has been deceived in this respect, for the last figure which appears in the review is entitled by Mr. Thomson "Native Ornaments" (p. 120), and, though occurring in his description of the Fly River district, represent, if I am not mistaken, Papuan Gulf natives, most probably Motu-Motuans.

Alfred C. Haddon.

I quite agree with Prof. Haddon's remarks above, which you have been good enough to submit to me, with regard to the mountaineers of the interior of New Guinea. They enter into details which, in an already over-long review, I had no space for. There is no doubt about the right-hand figure (p. 346) being *not* a mountaineer. I was less confident about the man on the left hand. The *two central figures* recall to me perfectly the people of Uburukara, of whom I took photographs in 1886, the plates of which were ruined during my disastrous march down the Goldie, and it was they who specially attracted my attention. With regard to the "Fly River" natives, I have never had the fortune to see any of them, but I certainly took the central figure to be one, while remarking to myself the likeness of the right-hand man to a Motuan—to men with whom he could be matched in any village indeed between the Gulf and Kerepunu.

104, Philbeach Gardens, S.W. Henry O. Forbes.

Some Lake Basins in France.

I regret that, through some inadvertence on my part, the name of the author of the "Atlas des Lacs Français," mentioned in my letter (p. 341) is wrongly printed. It should be Delebecque. In a letter received from M. Delebecque, he informs me that "the direction of the arrow on the map of Lake Léman is not exactly N., but N. 7° W." He informs me also that the curious funnel-shaped hole at the northern end of the Lake of Annecy, which I suggest may be a submerged swallow hole, is the site of a spring. This fact, however, need not be fatal to my suggestion, because the changes in level might convert what was once a swallow-hole into a spring. At present water at one time flows up from the dolinas of the Julian Alps, at another it drains off down them.

T. G. Bonney.

ON ELECTRIC SPARK PHOTOGRAPHS; OR, PHOTOGRAPHY OF FLYING BULLETS, &c., BY THE LIGHT OF THE ELECTRIC SPARK.[1]

I.

WHEN I was honoured by the invitation to deliver this lecture I felt some doubt as to my ability to find a subject which should be suitable, for there is a prevailing idea that in addressing the operative classes, it is necessary to speak only of some practical subject which bears immediately upon the most important industry of the place in which the lecture is being delivered; but it seems to me that this is a polite suggestion that the audience are unable to be interested by any subject except that particular one which occupies them daily. Now though I am a comparative stranger in Scotland I have heard quite enough, and I know quite enough, of the superiority of the education of you, who have the good fortune to live in this the most beautiful half of Great Britain, to be aware that, as is the case with all highly-educated men, you are able to take a keen and genuine interest in many subjects, and that I had better choose one to which I have specially devoted myself, if I do not wish to expose myself to the risk of being corrected. I will ask you therefore in imagination to leave your daily occupation and come with me into the physical laboratory, where, by the exercise of the art of the experimentalist, problems which might seem to be impossible are continually being solved. I wish as an experimentalist to present to you an example of experimental enquiry.

Let us suppose that for some reason we wish to examine carefully and accurately some moving object travelling, if you will, at so great a speed that, observed in the ordinary way, it appears as a mere blur, or perhaps at a speed so tremendous that it cannot be seen at all. In such a case, in order to get a clear view of the moving body we may either look through an aperture which is only opened for a moment as the body passes by, or we may suddenly illuminate the object by a flash of light when it is in a position in which it may be seen. If in either of these cases the hole is open, or the illumination lasts so short a time that the object has no time to move appreciably while it is in this way brought into view, we get what may in ordinary language be called an instantaneous impression and the object appears clear, sharp, and at rest. In the same way if we wish, with the object of obtaining a permanent record, to photograph a moving body we must either allow the eye of the camera to see through a hole for a moment, *i.e.* we must use a rapid shutter, and many such are well known, or we must, keeping the photographic plate exposed and the object in the dark, make a flash of light at the right time. As before, if the shutter is open or the flash lasts so short a time that the object cannot move appreciably in the time, then, if any impression is left at all it will be sharp, clear, and the same as if the body were at rest. The first method, that of the shutter, I do not intend to speak about to-night, but as, owing to the kindness of Mr. F. J. Smith, I have with me the most beautiful example that I have seen of what can be done by this method, I thought perhaps I should do well to show it. Mr. Smith was in an express train near Taunton, travelling at forty miles an hour, and when another express was coming up in the opposite direction at sixty miles an hour, *i.e.* approaching him at one hundred miles an hour, he aimed his camera at it and let a shutter of his own construction open and shut so quickly that the approaching train was photographed sharply. There is a special interest about this photograph; it shows one of the now extinct broad-gauge engines on the road. However, this is an example of the method which we shall not consider this evening.[2]

For our purpose we require what is called instantaneous illumination,—a flash of light. It is of course obvious that it depends entirely upon the speed of the object and the sharpness required, whether any particular flash is instantaneous enough. No flash is absolutely instantaneous, though some may last a very short time.

For instance, a flash of burning magnesium powder lasts so short a time that it may be used for the purpose of portraiture, and while it lasts even the eye itself has no time to change. The lower part of the second slide (Fig. A) is a photograph of the eye of Mr. Colebrook after he had been some minutes in a dark room, taken by the magnesium flash; the upper part is the same eye taken in daylight. The pupil is seen fully dilated and the eyelid has not had time to come down, and so we might reasonably say that the flash was instantaneous; it was for the purpose practically instantaneous. Yet when I make this large clock-face four feet across revolve at so moderate a speed that the periphery is only travelling at forty miles an hour and illuminate it by a magnesium flash you see no figures or marks at all, only a blur. Thus the magnesium flash, which for one purpose is practically instantaneous, is, tested in this simple way, found to last a long time. Let me now, following Lord Rayleigh, contrast the effect of the magnesium flash with that of a powerful electric spark. At each spark the clock-face appears brilliantly illuminated and absolutely at rest and clear, and if it were not that I could at once illuminate it by ordinary light it would be difficult to believe that it was still in motion.

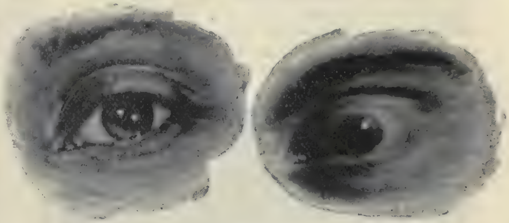

FIG. A.

Lower part. Upper part.

The electric spark has been often used to produce a flash by means of which phenomena have been observed which we ordinarily cannot see. For instance, Mr. Worthington has in this way seen and drawn the exact form of the splash produced by a falling drop of liquid.

Mr. Chichester Bell, Lord Rayleigh, Mr. F. J. Smith, and others have used the illumination produced by an electric spark to photograph phenomena which they were investigating. I am able to show one of Lord Rayleigh's, a breaking soap-bubble, in which the retreating edge, travelling something like thirty miles an hour, is seen with all the accuracy and sharpness that is possible with a stationary object. Mr. F. J. Smith has extended the use of sparks for the purpose of physiological enquiry, taking a row of photographs on a moving plate at intervals that can be arranged to suit the subject, and is thus putting in the hands of the much-abused experimental physiologist a very powerful weapon of research. I had hoped to show one of these series of an untechnical character, to wit, a series taken of a cat held by its four legs in an inverted position and allowed to drop. The cat, as every one is aware, seems to do that which is known to be dynamically impossible, namely, on being dropped upside down to turn round after being let go and to come down the right way up. The process can be followed by means of one of Mr. Smith's multiple spark photographs. However, his cats do not seem to like the experiments, and he has in consequence had so much trouble with them that his results, while they are of interest, are not, up to the present, siutable for exhibition.

---

[1] Lecture delivered at the Edinburgh meeting of the British Association by C. V. Boys, F.R.S.

[2] I have heard that a cannon-ball has been photographed by means of a rapid-shutter, but I have no direct information on the subject.

Let me now return to single spark photographs. We have seen that the magnesium flash, which for the purpose of portraiture is practically instantaneous, yet fails to appear so when so moderate a speed as forty miles an hour (and indeed a far lower speed) is used for the purpose of examining it. Is anything of the kind true in the case of the electric spark? Will the spark, by which we saw the clock-face absolutely sharp, after all fail to give a sharp view when tested by a much higher speed? I have taken such a spark and attempted (though I knew what the result would be) to photograph by its light the bullet of a magazine rifle passing by at the rate of about 2100 feet a second, or, what is the same thing, at about 1400 miles an hour; the result (Fig. 1) shows not a clear sharp bullet but a blur; the spark lasted so long a time that this bullet was actually able to travel half an inch or so while the illumination lasted. Thus we see, that if we wish to examine bullets, &c., in their flight, any electric spark will not necessarily do. We shall have to get a spark which while it gives enough light to act on the plate yet lasts so short a time that even a rifle bullet cannot move an appreciable distance during the time that it is in existence.

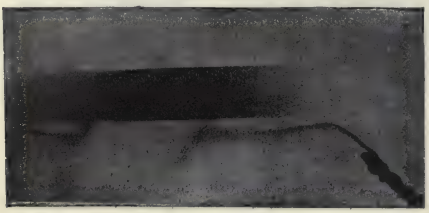

Fig. 1.

A knowledge of electrical principles enables one to modify the electrical apparatus employed to make this spark in such a manner that its duration may be greatly reduced without, at the same time, a very great sacrifice of light; but while this may be done it is important to be able to observe how long the spark actually lasts, when made by apparatus altered little by little in the proper manner. The desired information is at once given by the revolving mirror. For instance, every one is aware how, by a turn of the wrist, one may reflect a beam of sunlight from a piece of looking-glass so as to travel up the street at a most tremendous velocity; but suppose that, instead of being moved by a mere turn of the wrist, the mirror is made to rotate on an axle by mechanical means at an enormous speed; then, just as the rotation is more rapid, so will the beam of light travel at a higher speed. In the particular case that I am going now to bring before your notice, a small mirror of hardened steel was made by Mr. Colebrook, the mechanical assistant in the physical laboratory at South Kensington, mounted so beautifully that it would run at the enormous speed of 1000 turns a second (not 1000 a minute) without giving any trouble. The light from the spark was focussed by the mirror upon a photographic plate. Now if the light were really instantaneous, the image would be as clear and sharp as if the mirror were at rest; if, on the other hand, it lasted ong enough for the image to be carried an appreciable distance, then the photograph would show a band of light drawn out to this distance. The mirror is now placed on the front of the platform, and a beam of electric light is focussed by it upon the screen, from which it is distant about 20 feet. Now that I turn the mirror slowly, you see the spot of light drawn out into a band reaching across the screen, and this is described over and over again as the mirror revolves. Let us suppose that the mirror is revolving once a second, then it is easy to show that the spot of light is travelling at about 250 feet a second. It is not difficult therefore to see that if the mirror is revolving 1000 times as fast, the spot of light will traverse the screen 1000 times as fast also, *i.e.*, about 250,000 feet a second, or 160,000 miles an hour—a speed which is 200 times as great as that of a Martini-Henry bullet, while such a bullet only travels 14 times as fast as an express train. You will see, then, that it is not difficult to observe how long a spark lasts when its image can be whirled along at such a speed as this. I have now started the electro-motor, and the mirror is turning more and more rapidly. Now it gives a musical note of the same pitch as that given by the tuning-fork I am bowing; it is therefore turning 512 times a second. It is now giving a higher note, *i.e.* it is turning faster and faster, until at last it gives the octave, at which time it is turning 1028 turns a second. The band of light on the screen is produced by a spot now travelling at a still higher speed than that which I have just mentioned. I had hoped to have shown with this apparatus the actual experiment of drawing out the apparently instantaneous flash of an electric spark into a band of light, but I found that while it was easy to show the experiment in a small room, the amount of light was not sufficient to be seen in a great room like this. I must therefore be content to show one or two of the photographs which were taken lately in the physical laboratory at South Kensington by two of the students, Mr. Edser and Mr. Stansfield, whom I now take the opportunity of thanking. The next slide shows the drawn-out band of a particular spark made between magnesium terminals by the discharge of a condenser of 2½ square feet of window-glass, the spark being ⅛ inch long. Below the drawn-out band I have drawn a scale of millionths of a second. If the spark had been instantaneous it would have appeared as a fine vertical line. This line, however, has been drawn sideways to an extent depending on the duration of the spark. The spark, except at the ends, is extinct in rather less than one-millionth of a second, but the ends remain alight like two stars, being drawn out in consequence into two lines, which have lasted, as measured by the scale, as long as six or seven millionths of a second. Such a light is, therefore, seen to last when tested with this very powerful instrument so long that it seems absurd to call it instantaneous. It lasts too long for the purpose of bullet photography. In order to get sparks of shorter duration it is necessary to abolish the metal magnesium, in spite of the brilliant photographic effect of the two ends of the spark between knobs of this material, it is well to avoid all easily volatile metals, such as brass, because of the zinc that it contains, and instead to employ beads of copper or of platinum. In the second place, the duration of the spark proper, which in the last case was nearly a millionth of a second, can be reduced by (1) reducing the size of the condenser, but one must not go too far, as the light is reduced also; (2) by replacing any wire through which the discharge may have taken place by broad bands of copper as short as possible, this has the further advantage of increasing the light; and (3) the light may be increased without much change being made in the duration by making a second gap in the discharge circuit, the spark in which, however, must be hidden from the plate. Fig. 2 shows the trail of the best spark for the purpose of bullet

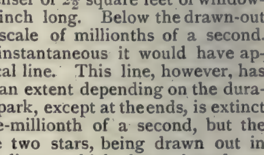

Fig. 2.

photography that I have obtained up to the present. In this case the surface of the condenser is one square foot, and the discharge is taken through bands of copper about two inches broad, and not more than about four inches long apiece. Extra good contact is made between these copper bands and the tinfoil surface by long radiating tongues of copper-foil soldered to the end of the copper bands. The knobs are platinum, but this seems no better than copper. The whole of the light is extinct in less than one-millionth of a second, while the first blaze, which is practically the whole spark, the tail being in comparison of no consequence, does not last so long as a ten-millionth of a second; in other words, it lasts so short a time that it bears the same relation to one second that one second bears to four months; or again, a magazine rifle bullet, travelling at the enormous speed that is now attained by the use of this weapon, cannot go more than one four-hundredth of an inch in this time. Other sparks of still less duration were examined, but this was chosen for the purpose of photographing bullets.[1]

Now, having obtained a suitable flash of light, I must next show how a spark may be used for the purpose of photographing a bullet in its passage This was first done by Prof. E. Mach,[2] of Prague, whose method is illustrated by the diagram Fig. 3. The squares on the right-hand side represent certain electrical apparatus by means of which a Leyden jar (J) is charged with electricity to such an extent that, while it is unable to make two sparks at B and A, it is nevertheless able to, and at once will, make a spark at B when the second gap at A is closed by a bullet or other conductor. The dotted lines represent wires through which the discharge then takes place. The spark at B, magnified by the lens *l* in front of it, then fills the field lens L with light, so that the camera K focussed upon the spark gap A will then receive an image of the bullet as it passes, and thus a photograph is secured. I am able to show two of these which Prof. Mach has kindly forwarded to me, and what I wish to point out is that in each of these photographs—and this is perhaps the most interesting feature which any of these exhibit—there are seen, besides the bullet and the wires which the bullet strikes in its journey, certain curious shades, one in advance of the bullet and one from the tail, while a trail is left behind very like that seen in the wake of a screw steamer. In fact, the whole atmospheric phenomenon accompanying the bullet is not unlike that seen on the surface of water surrounding and behind a steamship. These were seen for the first time, and their visibility by this method was, I believe, predicted by Prof. Mach before he made his first experiment.

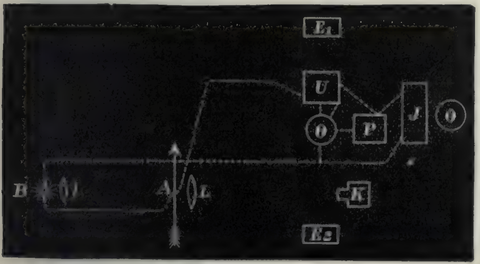

FIG. 3.

The part that I have played in this matter is after all very subordinate. I have attempted to simplify the means, and the results which may be obtained by the modified method which I have devised, are, I believe, in some respects—I don't say in all—clearer and more instructive than those obtained by the more elaborate device of Prof. Mach.

Fig. 4 is a diagram of the apparatus that I have used. C is a plate of window-glass with a square foot of tin-foil on either side. This condenser is charged until its potential is not sufficient to make a spark at each of the gaps E and E′, though it would, if either of these were made to conduct, immediately cause a spark to form at the other. *c* is a Leyden jar of very small capacity connected with C by wire, as shown by the continuous lines, and by string wetted with a solution of chloride of calcium, as shown by the dotted line. So long as the gap at B is open this little condenser, which is kept at the same potential as the large condenser by means of the wire and wet string, is similarly unable to make sparks both at B and E′, but it could, if B were closed, at once discharge at E′. Now suppose the bullet to join the wires at B, a minute spark is made at B and at E′ by the discharge of *c*, immediately C, finding one of its gaps E′ in a conducting state, discharges at E, making a brilliant spark, which casts a shadow of the bullet, &c., upon the photographic plate P. Though this is simple enough, the ends that are gained by this contrivance are not so obvious. In the first place the discharge circuit of C, via E and E′ is made of very short broad bands of copper, a form which favours both the brilliancy and the shortness of duration of the sparks; further, the double gap, of which E′ may be the longer, causes the intensity of the light of either spark to be greater than it would be if the other one did not exist—in a particular case the light of the shorter was increased six or eightfold—at the same time the duration is not greatly affected. For this reason the spark at E may be made very short, so that the shadow is almost as sharp as if the light came from a point. The spark formed at B, which is due to the discharge of *c* only, is very feeble, so that it is unable to act on the plate, whereas, had the discharge of C been carried round by B, the light at this point would hopelessly have spoilt the plate, and at the same time the light at E would have been feebler and would have lasted longer.

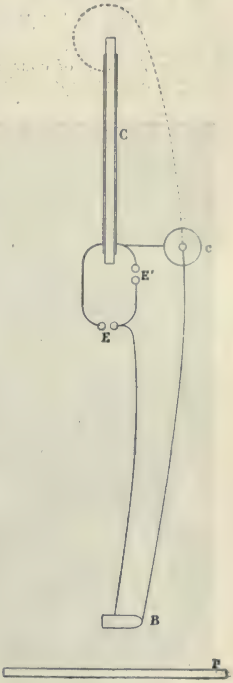

FIG. 4.

---

[1] These sparks were made to go off at the time that the mirror was facing towards the photographic plate by the employment of the same device as that described below in connection with Fig. 4. On the axle of the mirror an insulated tail of aluminium was secured, so as nearly to bridge a gap in the discharge circuit of an auxiliary jar of small capacity, there being a gap common to both circuits. A self-induction coil was used instead of the wet string, as being for this purpose preferable. The length of time that the spark lasted was thus measured without taking the electricity round by the mirror, which would have been quite sufficient to modify the duration of the discharge, and it was easier than making and adjusting a second reflecting mirror, which would have answered the same purpose.

[2] See NATURE, vol. xlii. p. 250.

The wet string, while it is for the purpose of keeping the condenser *c* charged a perfect conductor, is nevertheless, when this discharges at E′ and B, practically a perfect insulator; if it were replaced by wire then C would also wholly or partially discharge itself by B and E′. Finally, in avoiding all lenses one is free from the considerable absorption of the more refrangible rays which sparks provide in great abundance, and which are largely absorbed by glass. On the other hand the photograph is a mere shadow, but this is no drawback, for the bullet itself is on either system a mere silhouette, whereas the atmospheric phenomena are more sharply defined, and their character is more clearly indicated without lenses than is possible when they are employed.

Fig. 5 is a photograph of the apparatus set up in one of the passages in the Royal College of Science, in which the experiments were made. It is apparently of the rudest possible construction. The rifle seen on the left of the figure is of course made to rest freely on six points,[1] in order that its position every time it is fired may be the same. The bullet then traverses precisely the same course, so that wires placed in the line between holes in two cards made by one shot will be hit by the next. The two wires which the bullet joins as it passes by are set up in the box seen in the middle of the figure with the lid propped up so as to show the interior. The photographic plate is on the left-hand side and the spark when made is just within the rectangular prolongation on the right-hand side. Paper tubes with paper ends are placed on each side of the box to allow the bullet to enter and leave, and yet not permit any daylight to fall directly on the plate. All is black inside, and so the small amount of light which does enter the box through these holes is not diffused in any harmful manner. The large box at the back is a case 5 ft. long, filled with bran which stops the bullets gently without marking them. The little condenser is just below the rectangular prolongation of the photographic box, the large condenser is the vertical square sheet seen just to the right. The electrical machine used to charge the condensers is seen on the table. It is a very beautiful 12-plate Wimshurst machine made by Mr. Wimshurst and presented to the Physical Laboratory. This machine not only works with certainty but is so regular in its working that no electrometric apparatus is necessary. All that has to be done is to count the number of turns of the handle which are required to produce the sparks at E and E′ when the gap at B is not joined, and to count the number which are sufficient to produce a spark at E when the gap at B is suddenly closed. Then if the rifle is fired after any number of turns between these, but by preference nearer the larger than the smaller number, the potential will be right, the spark E, inside the box, and the spark E′, which is in sight outside the box, will be let off, and if a plate is exposed a photograph will be taken. If by chance the E′ spark is not seen then there is no occasion to waste the plate, another bullet may be fired after resetting the wires and the result will be as good as if one shot had not failed. When all is in order a failure of this kind is very rare. I also arranged a tube in the side of the box with a pocket telescope fixed in it and focussed on the wires. If a piece of white card or paper is placed in the line of vision and so as to be illuminated by a spark let off as above described but preferably much nearer the card, the bullet will be seen by any one looking through the telescope. I took this down, however, at once, as the photograph showed more than could ever be seen by the eye. The box seen just to the right of the rifle with a coil of wire upon it is the one in which the revolving mirror was fixed, and in which the trails of sparks made near the door at the end of the passage were photographed. The apparatus for photographing

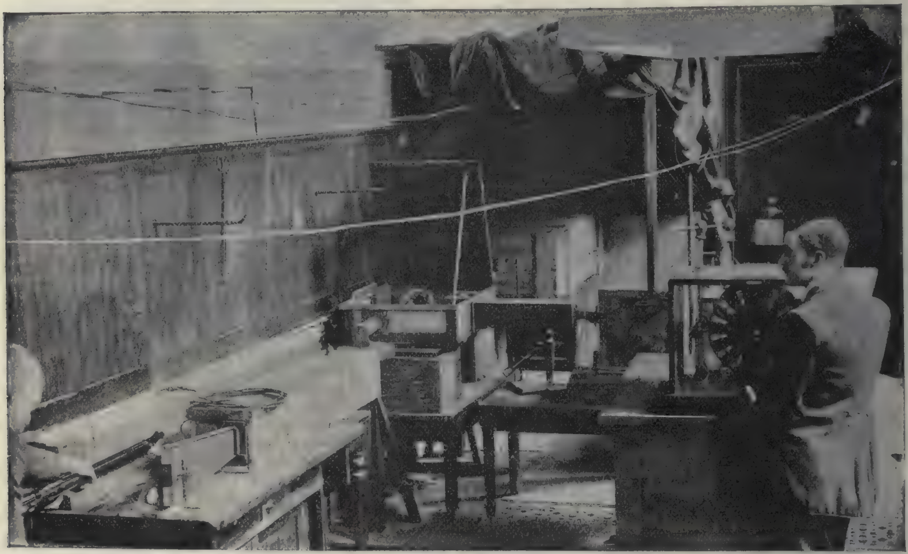

FIG. 5.

---

[1] Six independent points of support are required for a geometrical clamp. In this case a **V** support near the muzzle supplied two, a **V** support near the breach two more points, the rifle was pressed forward until a projection under the muzzle rested against the front **V**, thus allowing freedom of recoil, but otherwise preventing all uncertainty of position except that due to rotation in the V's which is made impossible by the sixth point, that is, the lower end of the stock resting sideways against a leather covered wooden bracket fastened to the same table to which the **V**'s were attached.

the bullets was put together and set up by Mr. Barton, a student, whose very skilful help in the matter and afterwards during the experiments I found of very great value.

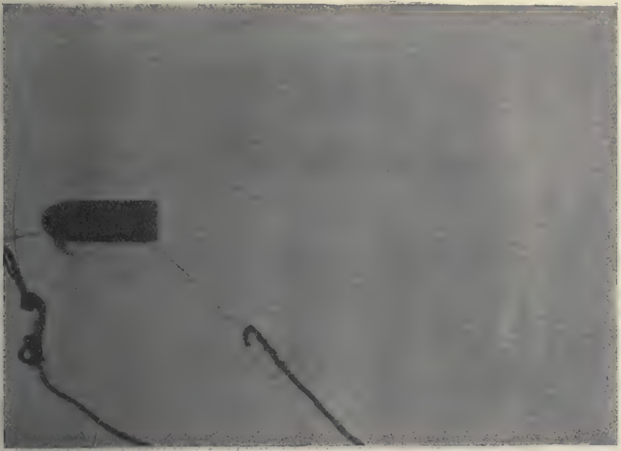

Fig. 6.

The first photograph which I am able to show was taken at Christmas, before the apparatus just described was put together. It was taken to see if the idea would practically succeed, merely using for the purpose bits of wire and other things to be found in any laboratory, which were set up in a dark room in less than an hour. The first shot was successful, but the sharpness of the photograph is not what it might be, owing to the fact that I used, for the sake of the brilliant light, a spark taken between magnesium terminals. However, the bullet is clearly enough defined, as are the wires which it has just struck. This is a photograph of a pistol bullet travelling only 750 feet a second. You will notice that unlike that taken by Prof. Mach, which represented a shot going at a much higher speed, this photograph shows no atmospheric phenomena surrounding the bullet. I would only add, in connection with this photograph, that by some accident the wad remained attached to the bullet in this case forming the enlarged tail. I do not know if this often happens; it must, if it does, seriously disturb the flight of the projectile, and introduce an anomaly that might not easily be accounted for.

The next photograph, Fig. 6, shows a bullet which has just left a Martini-Henry rifle. This is taken with the apparatus in its latest form, and the bullet appears perfectly sharp. There is no sign of any movement whatever in so far as the bullet itself is concerned.

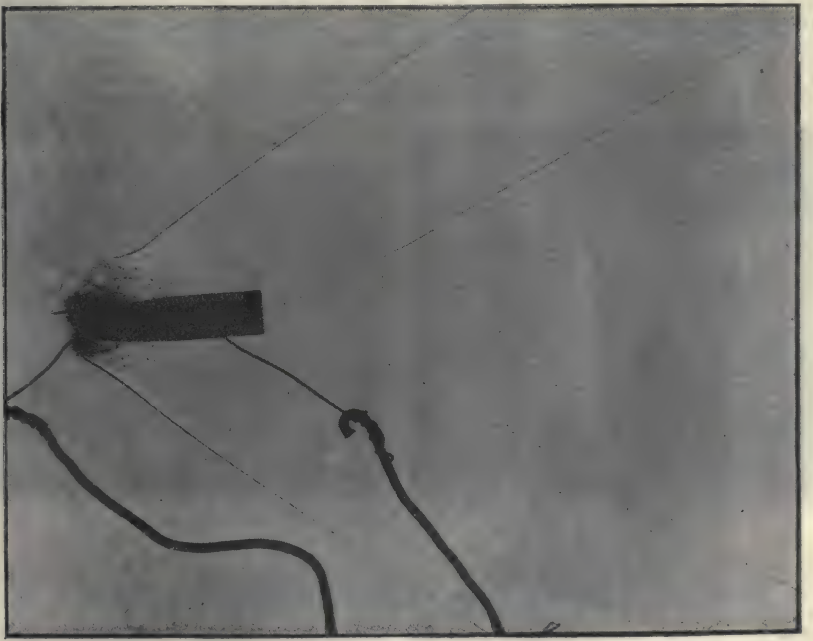

Fig. 7.

But now that we are dealing with a higher speed, namely, 1295 feet a second, there is evidence of the movement of the bullet in the form of a wave of compressed air in front and of other waves at the side of and behind the bullet. I shall explain this in a moment, but I would rather first show another photograph, Fig. 7, of a bullet travelling at a still higher speed, a magazine rifle bullet travelling about 2000 feet a second, in which these air waves are still more conspicuous, and in which a glance is sufficient to make it evident that the waves are much more inclined to the vertical than in the previous case.

Now as it may not be evident why these waves of air are formed, why their inclination varies with the speed, or why existing they are visible at all, a short explanation may not be out of place, more especially as they form the most interesting feature in the remaining photographs that I have to exhibit, which cannot, as a matter of fact, be properly interpreted without frequent reference to them.

I would first ask you to examine some still water into which a needle held vertically is allowed to dip. If you move the needle very slowly not a ripple is formed on the surface of the water; but as the needle is moved more quickly at first a speed is reached at which feeble waves appear, and then as the speed increases a swallow-tail pattern appears, the angle between the two tails become less as the velocity gets higher. Now in the case of water-waves the velocity with which they travel depends on the distance between one and the next, and for a reason into which I must not now enter either very long or very short waves travel more quickly than waves of moderate dimensions. If they are about two-thirds of an inch long they travel most slowly—about 9 inches a second. Now so long as the needle is travelling less quickly than this no disturbance is made; but when this speed is exceeded the swallow-tail appears. Suppose, for example, the velocity of the needle to be double the minimum wave velocity for water, *i.e.* let the needle move at 18 inches a second, and let it at any moment have arrived at the point p, Fig. 8. Then any disturbance, started when it was at the point A, must have travelled as far as the circle aaa in which $\mathrm{A}a$ is half $\mathrm{A}p$, similarly for any number of points BC, &c., between A and p any disturbance must have travelled as far as the corresponding circles bb, cc, &c., the result is that along a pair of lines, $p\mathrm{L}$, $p\mathrm{M}$, touching all the circles that could be drawn in this way, a wave will be found, and it is clear that as the velocity of the point is made greater the successive radii $\mathrm{A}a$ $\mathrm{B}b$, &c., will become in proportion to $\mathrm{A}p$ less, the circles will be smaller, and the angle between $\mathrm{L}p$ and $\mathrm{M}p$ will become less, while when the velocity is made less the reverse happens, until at last $\mathrm{A}a$ $\mathrm{B}b$, &c. = $\mathrm{A}p$ $\mathrm{B}p$, &c., and then when they exceed these quantities no lines $\mathrm{L}p$ $\mathrm{M}p$ can be drawn touching all these circles, there is no wave surface which the disturbances from all the successive points can conspire to produce, and the consequence is there is still water.

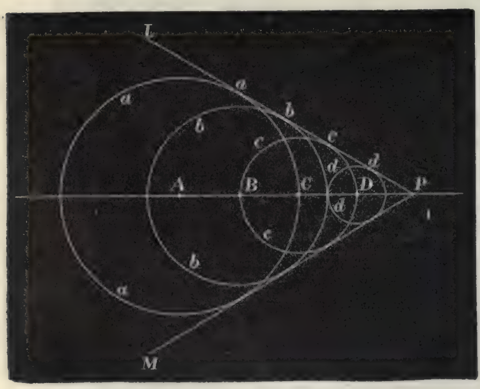

FIG. 8.

Now consider the case of a bullet moving through the air. Here again we are dealing with a case in which a wave cannot travel at less than a certain speed which is obviously the velocity of sound (1100 feet a second under ordinary circumstances), but, as in the case of surface waves on water, higher speeds are possible when the wave is one of very great intensity. The conditions in the two cases are therefore very nearly parallel; if the bullet is travelling at less than the minimum speed no waves should be formed—the pistol bullet at 750 feet a second did not show any—if the bullet is travelling at higher speeds than 1100 feet a second waves should be formed which should include a sharper angle as the speed is made to increase. This was found to be so in the case of the Martini-Henry and the magazine rifle bullet.

The curved form of the wave near the apex is due to the fact that when it is very intense, when the compression is very great, the velocity of travel is greater and, immediately in front of the bullet, the air is compressed to so great an exent that the wave at this part can travel at the speed of the bullet itself.

The reason why the waves should be visible at all is not difficult to follow. Consider a shell of compressed air though which rays of light from a point are made to traverse. These rays travel in straight lines, except where they meet a medium of different density, and the denser this is and the more nearly they meet this at a grazing incidence the more they will be bent towards the perpendicular. In comparison with water or glass a layer of compressed air has very little refractive power, and so rays which strike the shell anywhere except at the extreme edge are practically uninfluenced in their course and strike the plate practically in the same place that they would do if the shell of compressed air had not been traversed. But those rays ab, ab, Fig. 9, which strike the shell of air almost tangentially are bent inwards slightly at b and again at c, having traversed what is equivalent to a wide angle prism, and strike the plate at e, leaving the place d, where they would have gone had they not been refracted, dark; moreover at e they meet other rays which have been hardly at all refracted since they have passed actually into the shell and out again, and therefore e is doubly illuminated. The consequence is that a wave or shell of

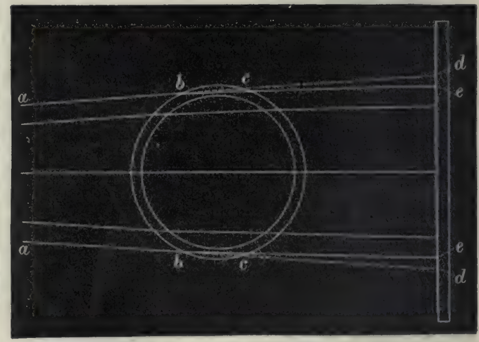

FIG. 9.

compressed air gives rise to an image on the plate, in which there is a dark line and a light line within it. Similarly a wave of rarefaction must produce a light line with a dark one within it.[1] An examination of the photograph Fig. 7 will make it evident that not only is the head wave a wave of compression, but the wave, which starts from the end of a kind of vena contracta behind the bullet, is also a wave of compression. It is a curious fact which requires explanation that the head and tail waves are not parallel to one another, and they do not show any sign that they would become parallel if they were continued indefinitely. This can only be due to either the tail of the bullet travelling considerably faster than the head, or to the actual velocity of propagation of the tail wave being less than that of the head wave. The effect observed is true and is not optical, being neither due to the refractive effect of the outer shell disturbing rays which are tangential to the inner shell, nor to an effect of perspective, for though the projection of a cone from a point upon a plane is only seen of the proper angle, when the perpendicular, dropped from the point upon the plane, passes through the vertex of the cone, yet when, as in the case of Fig. 11, where it passes within both cones, and more within the outer one than the inner one, the effect is to make the projections of both of a greater obtuseness, and of the outer one to a greater extent than the inner one; nevertheless an examination of the amount of this effect of perspective made by Mr. Barton showed that the distortion was not sufficient to be noticeable, as the difference in the acuteness of the cones certainly is.

(*To be continued.*)

NOTES.

ADMISSION to the Croonian Lecture, which Prof. Virchow, as we have already announced, is to deliver before the Royal Society at 4.30 p.m. on the 16th inst., will be by ticket, which may be obtained from the assistant secretary by introduction of a Fellow of the Society.

THERE will be widespread regret at the announcement which we now make that the distinguished geologist, Prof. K. A. Lossen, of Berlin, died there on the 24th ult. He had been ailing for some time, and suffered severely before he entered into his rest. In spite of the deafness which necessarily restricted his intercourse with men of science, he had formed a wide circle of friends who learned to appreciate the simplicity, candour, and geniality of his character, while at the same time they came to respect and admire more and more his wide range of knowledge, and that marvellous and apparently intuitive perception of the true characters of rocks which made him probably the best field-petrographer in Germany.

WE have received news of the death of Cav. Giuseppe Antonio Pasquale, for many years professor of botany in the University of Naples, and director of the botanic garden. Prof. Pasquale was the author of numerous articles on botany and cognate subjects. His earliest works of which we have cognisance were on the flora of Capri (1840), and the flora of Vesuvius (1842). In 1869 he published a more complete "Flora Vesuviana, confronte con quella dell' isola di Capri." He appears to have been appointed to the post of director of the Naples Botanic Garden in 1866, and the following year he published a catalogue of the plants cultivated there, together with a brief history of the garden.

THE German Government has established a biological Institute on the island of Heligoland, and has appointed Dr. Kuckuck its botanical director.

PROF. SCHWEINFURTH landed at Port Said on January 7, for an expedition into Upper Egypt which is intended to extend over several months. Dr. D. Riva, who accompanied Schweinfurth on his last journey, has undertaken an expedition to Eastern Africa in the vicinity of the river Giuba.

THE moss-herbarium of Dr. Rehmann and the Hepaticæ-herbarium of Dr. Gottsche have passed into the possession of the Botanical Museum of Berlin; the Botanical Museum of the University of Vienna has acquired the moss-herbarium of Hoppe; and the Botanical Institute of the German University at Prague the greater part of the valuable library of Prof. Willkomm.

THE Reale Instituto Veneto di Scienze, lettere ed arti proposes the following prize subjects:—(1) A lithological, mineralogical, and chemical investigation of the rocky, sandy, earthy and saline materials brought down under various conditions by one of the chief rivers of Venetia from the Alpine valleys, and deposited at various distances from the base of the Alps to the sea (prize, 3000 lire, date December 31, 1893). (2) A compendium of the history of mathematics, with a mathematical chrestomathy containing extracts from mathematical works of antiquity, the middle ages, the renaissance, and recent times down to Gauss (indicating in each case the reason for introducing the extracts), prize and date the same. Papers may be written in Italian, Latin, French, German, or English, and are to be sent in to the secretary with motto and sealed packet.

SIR ANDREW BARCLAY WALKER, who died on Monday, did much to promote intellectual life in Liverpool. The University College of that city has good reason to remember him as one of its most generous benefactors. He assumed the entire pecuniary responsibility for the erection of the Walker engineering laboratories, which cost about £20,000.

MR. O. M. EDWARDS, who was appointed to investigate the various conditions which have to be taken into account in connection with the proposal for the establishment of a Welsh University, has completed his inquiries and forwarded his report to the Vice-President of the Committee of Council on Education. A writer in the *University Correspondent* says the report is practically a pamphlet of about eighteen octavo pages, containing a short account of the origin and progress of the educational movement in Wales, and intended to supplement the information already possessed by the Department of Education on this head. It contains a succinct epitome of the various schemes proposed—the Shrewsbury Charter, the proposals of Dr. Roberts and Prof. Evans; gives the state of efficiency of Lampeter and the three Welsh colleges; contrasts them with those at Leeds and Manchester; and points out how far, more or less, the Welsh institutions are prepared and adapted, in point of staff, students, accommodation, and appliances, to receive similar powers.

THE Municipal Council of Paris has been giving names to some new streets, and changing those by which various old streets have hitherto been known. The names selected for use are for the most part those of illustrious Frenchmen, and it is significant that among them are some well-known men of science. The Rue du Battoir, for instance, is henceforth to be called the Rue Quatrefages, in memory of the famous anthropologist; and the Rue Claude-Vellefaux becomes the Rue Charles-Robin, in memory of the great physician. A new street is called after

---

[1] It may be worth while to point out that the dark and light lines are, and ought to be, parallel to one another as soon as they are so far away from the shadow of the bullet as to be practically straight lines. For if the thickness of the shell is divided up into a series of elements the ray passing through any one of these will meet with a refractive medium, which is less effective as the diameter of the part of the shell considered is greater, while the refractive angles of the elementary prisms become inclined more so as to compensate for the diminished density.

Ernest Renan. This is only one of many indications of the respect in which science is held in France. We shall probably have to wait some time before it is decided by the municipal authorities of London that streets shall be known by the names, say, of Darwin and Joule.

THE atmospheric disturbance referred to in our last issue as crossing this country on Tuesday, February 21, reached the English Channel on the following day; afterwards its progress eastwards was unusually slow, and north-west winds belonging to the rear of the disturbance were experienced. Frost occurred during the night of the 22nd in many parts, and towards the close of last week the daily maxima fell below 40°, except in the extreme west and south-west, while in the midland counties frost continued throughout the day, and hail and snow occurred in many places. After a temporary improvement in the south and south-east districts on Saturday, a deep depression reached our south-west coasts from the Atlantic, causing strong gales on Sunday, and very severe snowstorms in Scotland, with heavy rain in other parts of the country, the fall exceeding an inch and a quarter on the north-east coast. By Sunday evening the disturbance had reached the north-east of England, where the barometer had fallen to 28·6 inches; this depression was preceded by severe frost in Scotland, the minimum temperature recorded at Nairn being as low as 11°. On Monday a north-westerly gale was blowing in Scotland, accompanied by snow, and on the same day a new depression arrived over the south-west of England, accompanied with further heavy rainfall in the southern half of the kingdom, and strong winds and gales in the English Channel; frost also occurred in many parts. After these gales had subsided, the weather still remained in a very disturbed and unsettled condition. The *Weekly Weather Report* issued on February 25 showed that the temperature for that week was generally 1° to 2° below the mean in Great Britain, and 3° to 4° below in Ireland; also that the rainfall was much in excess of the average in the southern and eastern parts of England.

THE Report of the Meteorological Council for the year ending March 31, 1892, just presented to Parliament, reviews the work of the office under four heads: (1) *Ocean Meteorology*. The charts for the Red Sea were in an advanced state, and the extraction of data for the current charts of the Atlantic, Pacific, and Indian Oceans, and of data referring to the southern ocean, was being actively carried on. In this branch of the work the supply of instruments to ships is supplemented by the supplies to remote stations, when favourable opportunities occur. (2) *Weather Telegraphy and Forecasts*. An important station has been established at the North Foreland, and the work generally in this branch continues to increase; both the Daily and Weekly Weather Reports have been extended and improved. Weather forecasts are prepared three times daily; the total percentage of success of the 8h. 30m. p.m. forecasts which appear in the morning newspapers was 80, being 2 lower than in 1890-91. The results were best in England south, and worst in Scotland west. The percentage of success of the forecasts issued during haymaking was 89 per cent. Although these forecasts are issued solely for the benefit of farmers, the Agricultural Department does not at present aid in their dissemination. (3) *Land Meteorology of the British Isles*. Under this head are included all observatories, anemograph stations, and volunteer stations, necessary for the study of the periodic variations of the meteorological elements, and of climatology. Among the publications we may specially mention the "Harmonic Analysis of the Hourly Observations at British Observatories," which is probably the first systematic publication of the description that has hitherto been brought out by any of the established meteorological institutions. (4) *Miscellaneous*. This head gives an account of the various researches now in hand, among which are included investigations relating to rainfall, sunshine, fog, &c. It also contains particulars relating to the work done in cataloguing books and pamphlets, and also a classified summary of expenditure. A special note contains an account of the anemometer comparisons carried out by Mr. W. H. Dines, with the aid of a grant from the Council.

THE Meteorological Council have just issued a summary of the *Weekly Weather Report*, 1892, containing, among much other information of importance to agricultural and hygienic meteorology, an appendix showing the rainfall and mean temperature for the 27 years 1866 to 1892, for each of the 12 districts into which the United Kingdom is divided for the purpose of weather forecasts. The values show that the average rainfall for the whole of the British Islands is 34·9 inches; in the wheat-producing districts the average fall for the year is 28·2 inches, while for the grazing, &c., districts it is 41·6 inches. The wettest district is the west of Scotland, where the average annual rainfall is 45·5 inches, and the driest is the east of England, where the average amount is 25·8 inches. The values for the year 1892 varied considerably in different localities; the wettest district during the year was the north of Scotland, where the fall was 5·6 inches in excess of the average, while in the south-west of England the deficiency was 12·5 inches. As regards temperature, the average for the whole area for the 27 years (omitting the Channel Islands) was 48°·4, and the mean difference of temperature between the wheat-producing and grazing districts scarcely amounted to a degree. The average value for the whole area during 1892 was 1°·6 below the mean for the 27 years; there was a deficiency in every district during that year, the greatest amount being 2°·3 in the east of Scotland, and the least, 0°·9 in the south of England; in fact, it was the coldest year experienced since 1879.

AN electrical actinometer was used by Messrs. Elster and Geitel, of Wolfenbüttel, in their measurements of the sun's ultraviolet radiation. The instrument, as described in *Wiedemann's Annalen*, was based upon the action of ultraviolet light in accelerating the dissipation of an electric charge from a cathode of amalgamated zinc. By exposing a plate of the metal to the light from a stream of sparks from an induction coil at various distances, and determining the dissipation of a negative charge imparted to it, this was proved to be a linear function of the light intensity. In its portable form the instrument consists of a cylinder which can be directed towards the sun, and into which a charged sphere of amalgamated zinc is introduced by means of an insulating handle. The fall of potential during a few seconds' exposure is determined by means of an Exner electroscope. Messrs. Elster and Geitel have made observations for each month in the year, and found the ultraviolet radiation to exhibit an inverse relation to atmospheric electricity. Comparisons were also made of the results at various heights above the sea-level, the stations being the summit of the Sonnblick (3100 m.), Kolm-Saigurn, in the adjoining valley (1600 m.), and Wolfenbüttel (80 m.). It was found that 40 per cent. of perpendicular ultraviolet rays from space reached the level of Sonnblick, 23 per cent. of these were absorbed before reaching the next station, and only 47 per cent. of the remainder arrived at the level of Wolfenbüttel.

TEN years ago there was some correspondence in NATURE on the subject of snow-rollers. The phenomenon does not seem to occur very often, so that some interest attaches to a communication in *Science* (February 3), describing an instance noted last year at Milledgeville, Ohio. Mr. W. S. Ford says that on the morning of January 30, 1892, the clean level fields surrounding that town were covered with balls of snow, varying in size from three to five inches long and from one to two inches wide.

Wheat-fields and meadows abounded with these balls, and suggested, at first sight, that a troop of school-boys had been having a battle with the snow. Two fields, of thirty acres each, that came under Mr. Ford's observation (one a new-sown wheat-field and the other a meadow) were literally covered with these "snow-rollers," there being at least 500 on the acre. Road-sides and lots contained a few, and he noticed them on house-tops and straw-ricks. On close investigation, he found the balls to be uniformly light and fragile, so that to lift one and preserve its form was impossible. Some were oblong, some almost spherical, while others resembled a tea-cup or small bowl. There were no tracks behind them, or, if these had been made, the falling snow had obliterated them. The accompanying weather conditions were as follows:—The ground had been covered with snow for three weeks. A crust had formed on the top, thick and firm enough in places to bear up a person. This thawed a little during the afternoon of the 29th. The ensuing night was warm, the mercury registering 40° F. By ten o'clock a brisk wind was blowing, which increased in velocity, and soon the snow began to fall in large, moist flakes. The morning showed that about a half-inch had fallen on the crust, and on this lay the balls. The phenomenon was reported from several places in the vicinity, chiefly in the Fayette County, and from Clinton County, which adjoins it on the west, but nowhere did the rollers extend uninterruptedly over any great area.

IN November last, according to a writer in the Journal of the Straits Branch of the Royal Asiatic Society, there was in Singapore one of the largest specimens of the Mias or Orang-Utan ever captured; it was a male, and probably of the species known as *Simia satyrus*, Linn., or the Mias Pappan of the Dyaks. The animal was captured in Borneo, and bought by a native dealer in Singapore, who eventually sold him to a German ship's captain, by whom he has been, it is believed, taken to Germany. As far as the writer could judge, his height must have been close on 4 feet 5 inches. The cage in which he was confined was 4 feet 2 inches or thereabouts in height, and he could easily touch the top of it with his head without standing erect. His face was immensely broad, the cheeks being flattened out sideways into a sort of disc. The hair was long (about 4 inches) and thick and of a bright red colour, and he had a distinct short pointed beard. The eyes were dark brown.

A WRITER who signs himself "Tutuila" contributes to the current number of the Journal of the Polynesian Society some interesting notes on the races known as the Tokelaus, or Line Islanders, called by themselves the Kai-n-Abara, which means "people of our land." The Kai-n-Abara inhabit all the islands of the Gilbert Group, Nanumea, and Nanumanga in the Ellice Group, and Banapa or Ocean Island. They are apparently of the Micronesian type, but although they have long straight hair, and are more of a copper colour than brown, they are not pure Micronesian. They are intelligent, can reason inductively, are brave, having a very respectable share of courage, and are extremely pugnacious, both sexes fighting like fiends on the least provocation. In every township there is a large house called "maneabau," in which the members of each family of "aomata" or "gentry" have a certain space allotted to them. All the social government is carried on in this house, and everything of a public nature is discussed in it. Decision is given by general vote, the majority carrying their point. The older and wealthier landowners have most influence where there are no nobles, but do not seem to have more votes than any one else. A woman can vote and speak as well as a man, and in general the women decide the question, unless it is one of war against another island.

MR. A. J. CHITTY records in the new number of the *Entomologist's Monthly Magazine* that in the neighbourhood of Forres, Morayshire, where he spent six weeks last autumn, he found that Coleoptera were very abundant. He captured specimens of a good many species new to the district, and one or two which had not, he believes, been recorded before from Scotland.

A LIST of the Batrachia in the Indian Museum, by W. L. Sclater, has been issued by the trustees of the institution. The arrangement and nomenclature are formed on Mr. Boulenger's work in the British Museum catalogues, and the Reptiles and Batrachia in the "Fauna of British India" series.

AN interesting paper on the were-wolf in Latin literature, by Kirby W. Smith, is printed in the new number of the Johns Hopkins University Circulars. The were-wolf is a person who, either from a gift inborn or from the proper use of certain magic arts of which he has learned the secret, can change himself into a wolf of unusual size and ferocity; or, furthermore, the transformation may be unavoidable, owing to the curse or charm of some outside power, and not to be got rid of until a fixed period has elapsed or various conditions, more or less difficult, have been complied with. Such enchantments are common in the folk-lore of all nations, but, on Roman ground, they do not appear in connection with the were-wolf story. Mr. Smith mentions the were-wolf story told by Petronius, who describes how the companion of the freedman Niceros took off his clothes, and, becoming a wolf, began to howl and took to the woods. Niceros tried to pick up the clothes, but found they had all turned to stone. The wolf was wounded in the neck with a spear, and afterwards Niceros found his comrade in bed, while his neck was being dressed by a doctor. Here the transformation is attributed to a power born in the person, and Mr. Smith thinks that this may be the nearest approach to the original form of the superstition, because "among savages, these modern types of early humanity, just such stories are more or less common." The other class of Roman were-wolf stories—those in which the change is effected by means of a charm—simply form one of a large number of different transformations, the theory and methods of all being practically the same.

WE have received the first part of the new *Contributions from the Botanical Laboratory of the University of Pennsylvania*. It contains papers by Dr. J. T. Rothrock on a monstrous specimen of *Rudbeckia hirta*, and on a nascent variety of *Brunella vulgaris*; by Dr. J. M. Macfarlane, contributions to the history of *Dionæa muscipula*; by Mr. J. W. Harshberger on an abnormal development of the inflorescence of Dionæa; by Mr. H. Trimble on Mangrove tannin; by Dr. W. P. Wilson on *Epigæa repens*, and on the movements of the leaves of *Melilotus alba*.

THE paper by Dr. Macfarlane on Dionæa is of great interest and confirms the statement previously made by him that, to produce closure of the leaf, two distinct stimuli are required, which may be communicated to the same hair, or to different hairs on the same half, or to hairs on opposite halves of the leaf. He regards the leaf, previous to secretion, as in a state of tetanic contraction, resulting from a series of stimuli, which may either be partially or entirely mechanical, thermal, luminous, chemical, or electric. The so-called "hairs" are not true hairs, but emergences, and their structure is described in detail. Each consists of three distinct regions, the joint, the base, and the shaft. While previous observations, such as those of Darwin and Prof. Burdon Sanderson, have been made on plants of Dionæa under abnormal conditions of cultivation, Macfarlane's are especially valuable as having been made on the plant in its native condition; and this is also the case with those of Mr. Bashford Dean, contributed to the Transactions of the New York Academy of

Sciences. Mr. Dean states that there is a marked difference in the irritability of different leaves; that the leaves usually fail in capturing the larger and more active insects; that even small insects constantly escape; and that the leaf repeatedly closes on inorganic and vegetable objects.

MR. W. SAVILLE-KENT'S book on "The Great Barrier Reef of Australia" will be ready for publication before the end of the present month. It will include a series of photographic views of coral reefs of various construction from several selected localities, with similar and also coloured illustrations and descriptions of the living corolla, coral-polyps, and other marine organisms commonly associated on the reefs. Meanwhile, Messrs. W. H. Allen and Co., who are to publish the book, have issued enlarged and very beautiful copies of some of the principal illustrations. These are intended for the use of museums, colleges, and natural history societies, and will certainly be highly appreciated wherever they may happen to be introduced.

A TRANSLATION of Prof. Weismann's "Das Keimplasma," recently reviewed in NATURE, has been issued in "The Contemporary Science Series" (Walter Scott). The translators are Prof. W. N. Parker and Harriet Rönnfeldt, who have done their work carefully. In the preface Prof. Parker explains that in the case of special technical terms which have no recognised English equivalents he has added the German words in brackets the first time they are used. He has had the great advantage of being able to consult Prof. Weismann personally with regard to many of the more difficult passages.

THE County Council of Northumberland has issued a valuable pamphlet, by Dr. W. Somerville, giving an account of experiments made last season throughout Northumberland with a view of gaining practical information regarding some points connected with the economic manuring of the turnip crop.

MESSRS. METHUEN AND CO. have added to their "University Extension Series" a volume on "The Mechanics of Daily Life," by V. P. Sells. The author makes no attempt at the mathematical treatment generally adopted, but seeks rather to use the subject "as a means of scientific training, and as an illustration of the method of examining nature by reasoning and experiment."

MESSRS. CASSELL AND CO. are publishing in monthly parts a new issue of Dr. Robert Brown's "Our Earth and its Story," with many coloured plates, maps, and upwards of 700 illustrations.

TWO important papers upon the ready preparation of large quantities of the more refractory metals by means of the electric furnace are contributed by M. Moissan to the current number of the *Comptes Rendus*. The "electric furnace" is simply a small furnace constructed of lime, so arranged that it can be intensely heated by a very powerful electric arc. A quantity of magnesia, which M. Moissan finds to be perfectly stable even at this high temperature, is first placed in the cavity of the furnace, and upon this the crucible of retort-carbon containing a mixture of powdered carbon and the metallic oxide to be reduced. When the metal is volatile a current of hydrogen is passed through the furnace, and the vaporised metal is condensed in a comparatively cool receiver. In this manner M. Moissan has succeeded in rapidly preparing considerable quantities of the metals of the alkaline earths, calcium, strontium, and barium. If the metal is not sensibly volatile it is left in the crucible after the reduction in the form of an ingot. The rare metal uranium, and the metals manganese and chromium belong to this category, and their preparation forms the subject of M. Moissan's two communications.

METALLIC uranium was prepared with great difficulty, and only in small quantities by Peligot, by reducing the oxide with an alkali metal. At ordinarily procurable temperatures the various oxides of uranium are practically irreducible by carbon. This no longer obtains, however, at the extremely high temperature of a very powerful electric arc. The nitrate of uranium is first calcined in a porcelain crucible, whereby a reddish-coloured mixture of the sesquioxide and of the green oxide U_3O_4 is obtained. This mixed oxide is then well ground with a very slight excess of powdered carbon, and the whole tightly packed in the crucible of retort-carbon, which is afterwards placed in position in the lime furnace. Upon submitting the mixture in the crucible to the action of the arc produced by a current of 450 ampères, the reduction is completely effected in a few minutes. The ingot of uranium thus produced exhibits a brilliant fracture and great hardness. It possesses the peculiar property of sending forth a shower of incandescent sparks when struck against a piece of porcelain, or when fragments of it are shaken about in a glass flask, reminding one of the combustion of particles of freshly-reduced iron when allowed to fall through the air. The yield of the metal is very considerable; thus in one experiment of twelve minutes' duration an ingot weighing over two hundred grams was produced. The metal is not quite free from carbon, the amount of the latter depending upon the excess used. M. Moissan is now engaged in perfecting a ready mode of refining it.

IN order to prepare metallic manganese the protoxide is mixed with carbon as in the case of uranium, and the mixture submitted to the arc produced by a current of 300 ampères. The reduction is completely effected in five or six minutes, an ingot of 120 grams being readily obtained. The comparatively weaker arc derived from a current of only 100 ampères gives the same yield in 10–15 minutes. Any large excess of carbon is to be avoided as carbides of manganese are then produced. If an excess of the oxide is employed the metallic manganese obtained is almost pure, and may be preserved unchanged in open vessels. The carbides, however, are rapidly attacked by the moisture of the atmosphere, and if thrown into water evolve a gaseous mixture of hydrogen and various hydrocarbons. Chromium has always been found hitherto to be much more difficult to reduce than manganese, but complete reduction occurs in 8–10 minutes in the electric furnace, employing a mixture of the sesquioxide and carbon and a current of 350 ampères, the yield being an ingot of 100 grams. A current of only 30 ampères, however, is sufficient to produce ten grams of the metal in half an hour's time. Moreover, it is possible to refine the somewhat impure (from carbide) metal by a simple repetition of the process in presence of a fresh quantity of the sesquioxide. The pure chromium thus obtained is completely transformed into the volatile chloride when heated in a stream of chlorine. The reduction in the electric arc succeeds equally well with crude chrome iron ore, an alloy of iron and chromium being obtained from which the chromium may very readily be converted into chromate by projecting it into fused nitrate of potash or soda and subsequent extraction with water.

NOTES from the Marine Biological Station, Plymouth.—During the past week ephyræ of *Aurelia* have become quite plentiful in the Sound. The Anthomedusæ have been represented by numbers of the charming *Rathkea octopunctata* of Haeckel; and the Leptomedusæ (which are still scarce) by isolated examples of several species, including the *Thaumantias octona* of Forbes. Ctenophore ova and several larval and young Ctenophores have been noticed. The proportion of Polychæte larvæ and of Cirrhipede *Nauplii* remains fairly constant; while there has been an appreciable increase in the numbers of Brachyurous Zoœæ. The Hydroid *Sertularia argentea* and Actinian *Cereus pedunculatus* (=*Sagartia bellis*) are now breeding.

THE additions to the Zoological Society's Gardens during the past week include a Mozambique Monkey (*Cercopithecus pygerythrus*, ♂) from East Africa, presented by Mr. R. Hughes; a Bonnet Monkey (*Macacus sinicus*, ♀) from India, presented by Mr. W. Yeoman; two Herring Gulls (*Larus argentatus*) British, presented by Mr. J. S. Williams; an Ariel Toucan (*Ramphastos ariel*) from Brazil, presented by Mr. Ellis Edwards; a Great Eagle Owl (*Bubo maximus*) European, presented by Commander E. G. Rason, R.N.; two Spengler's Terrapins (*Nicoria spengleri*) from Okinawa Shima, Loo Choo Islands, presented by Mr. P. Aug. Holst; two Tuatera Lizards (*Sphenodon punctatus*) from New Zealand, presented by Capt. Worster; a Spiny-tailed Mastigure (*Uromastix acanthinurus*) from Algeria, presented by Miss Rigley; a Cuming's Octodon (*Octodon cumingi*) from Chili, deposited; an Eland (*Oreas canna*, ♂), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

COMET BROOKS (NOVEMBER 19, 1892).—The following ephemeris has been computed by Ristenpart (*Astronomischen Nachrichten*, 3154) from five normal places of this comet, using the elements—

$$T = 1893, \text{ January } 6{\cdot}529304 \text{ M.T. Berlin.}$$

$$\left.\begin{array}{rl} \omega = & 85^\circ\ 12'\ 51''{\cdot}0 \\ \Omega = & 185\ \ 36\ \ 29{\cdot}0 \\ i = & 143\ \ 51\ \ 45{\cdot}9 \end{array}\right\} 1890{\cdot}0$$

$$\log q = 0{\cdot}0774148$$

12h. Berlin M.T.

NOVA AURIGÆ.—Last week we mentioned that Mr. Fowler's observation of this nova consisted of two bright nebula lines situated near wave-lengths 5006 and 4956, the former being only slightly brighter than the latter. In *Astronomischen Nachrichten*, No. 3153, Mr Huggins, in a note dated February 11, writes with respect to his observations on February 7, 8, and 10, using a 4-inch Rowland grating (14,438 lines to the inch) and the second order, that the band was "resolved into a long group of lines extending through about 15 tenth-metres. The lines appeared more or less bright upon a faintly luminous background which could be traced a little beyond the lines at both ends of the group. Two lines, the brightest in the group and about equally bright, formed the termination of the group towards the blue; and a line nearly as bright as these was seen about the middle of the group. The group is therefore brighter at the blue end, but it does not possess any of the features of a fluting. No contrast in the spectroscope could well be more striking than that which this extended group of lines forms with the narrow and defined principal line in the nebula of Orion."

HYDROGEN LINE Hβ IN THE SPECTRUM OF NOVA AURIGÆ.—Owing to the curious appearance of the Hβ line in the spectrum of Nova Aurigæ, this line first appearing double and then afterwards quadruple, various explanations have been put forward to account for this peculiarity. From the hypothesis of two bodies, which did not agree with the facts observed, that of three and more bodies was suggested, until at last it was supposed that six bodies in all were in question. This supposition seemed most improbable, and since then the matter has been allowed to lie dormant. With reference to the behaviour of this line in the spectrum of vacuum tubes, Herr Victor Schumann (*Astronomy and Astrophysics* for February) has made some very interesting experiments, taking great care to use the hydrogen in as dry and pure a state as possible. We will here only refer to the most important part of the paper, leaving the reader to refer to the article itself for the apparatus, &c., employed. The photographic plates employed were made by himself according to the "silveroxydammonmethode" of Dr. Eder, of Vienna. Working with pressures from 1 to 100 mm. of mercury, the results obtained at those of 65, 80, and 100 gave the following results:—At 65 mm. Hβ and Hγ were most prominent, and in the negatives they were well defined, "although the sharpness of their edges is injuriously affected by broad, hazy fringes of considerable intensity, which shade off into the background from both sides of the line." Under a pressure of 80 mm. Hβ lost most of its definition, and close to it on each side were observed two fine thin lines, the fringe also being present but a little wider than before. Hγ, although increased in breadth, has lost its definition. With a pressure of 100 mm., "the more refrangible component of the pair of lines just mentioned as belonging to Hβ, has disappeared, and in its place has appeared Hβ itself, broad, but very weak; near by on the lower side one observes a thin line twice." With reference to the fringe of Hβ he says, it has now "spread itself out more towards the blue than the red, thus displacing the middle of it towards the blue." Hγ remains a very weak line. These observations showed that of all the hydrogen lines Hγ was the only one that showed reversal as well as displacement, and he concludes with the remark that "if it be asked whether the phenomena of reversal as observed in my hydrogen spectra furnish in themselves an explanation of the reversal of the lines in the spectra of Nova Aurigæ, the answer must be decidedly in the negative."

COINCIDENCE OF SOLAR AND TERRESTRIAL PHENOMENA.—Since Prof. G. E. Hale commenced his solar researches at the Kenwood Observatory, much has been added by him to our knowledge of the physics of the sun. Faculæ, for instance, which were supposed to be scattered only here and there on the solar surface, are now found, by means of the fine spectroheliograph, to occupy largely both hemispheres, and sometimes to extend in almost unbroken belts across the disc. This fact has led him to consider the question of the probability of chance coincidence between terrestrial magnetism and spots and faculæ (*Astronomy and Astrophysics*, for February), his attention being especially brought in this direction through a paper communicated to the Paris Academy of Sciences by M. Marchaud. M. Marchaud, in summing up his results after an examination of both solar and magnetic observations, says, with reference to the curve of magnetic intensity, that "each of these maxima sensibly coincides with the passage of a group of spots or a group of faculæ at its shortest distance from the centre of the disc." From an examination of 142 photographs of the sun, obtained between January 25 and December 3, 1892, at the Kenwood Observatory, Prof. Hale finds that no less than 132 show "one or more groups of faculæ on the central meridian, *i.e.* at their shortest distances from the centre of the solar disc." The chances, therefore, that at any given time one or more groups may be located at the central meridian, he finds as 0·93. This value, as he remarks, will be reduced for periods of decreased solar activity, but "coincidences noted in epochs like the present can hardly be regarded as of great importance."

"ASTRONOMICAL JOURNAL" PRIZES.—In addition to the prizes already offered, and to which we have previously referred (NATURE, vol. xlvii., Astronomical Column, p. 282), two extra ones, subject to the same conditions, are now to be presented. The first is to be given to "the observer making, by Argelander's method, the best series of determinations of maxima and minima of variable stars during the two years to 1895, March 31." The sum in this case is two hundred dollars. It is stated that "a principal basis for the award is to be the extent to which the determinations will contribute to our better knowledge of the periodic variables by furnishing the largest number of maxima or minima of the largest number of stars, having especial regard to stars whose characteristics are at present not very well known." The award of four hundred dollars will be given for the "most thorough discussion of the rotation of the earth, with reference to the recently discovered variations of latitude." The manuscript (which will be returned to the author) is to be transmitted to some one of the judges not later than March 31, 1895.

For the award of these prizes the judges are Messrs. Asaph Hall, Seth C. Chandler, and Lewis Boss.

GEOGRAPHICAL NOTES.

THE Liverpool Geographical Society has issued its first annual report, which, although not showing a very cordial reception of the new society by the public, is not without some promise of future growth. The Earl of Derby is President, there are twenty-two Vice-Presidents, a substantial Council, and a staff of honorary officials. Staff-Commander E. C. Dubois Phillips has been appointed Secretary. The second year of the society was inaugurated by a lecture on the Discovery of the Alps, by Mr. D. W. Freshfield, President of the Alpine Club, and one of the Secretaries of the Royal Geographical Society. Other lectures have been arranged for, and it is to be hoped that the membership of the society will rapidly increase.

THE tenth German Geographentag is announced to meet in Stuttgart on April 5, 6, and 7. The programme includes (1) The special geography of Würtemberg and the researches on the lake of Constance; (2) Recent geographical investigations with special reference to desert phenomena; (3) Cartography; (4) Economic or applied geography; and (5) School geography. An exhibition will be held at the same time, mainly of objects illustrative of the geography of Würtemberg.

PROF. PENCK has a long paper in the March number of the *Geographical Journal*, describing in detail his scheme for a map of the world on the scale of 1 : 1,000,000. The importance of having maps of every country on one scale has long been recognised by working geographers; but, with the exception of the little atlas on gnomonic projection by the late R. A. Proctor, we do not know of any effort having been made to place such maps before the public. The minute scale of the work referred to reduced its value to a minimum. Prof. Penck's scheme is one of great magnitude. He would allocate the production of the map to the Governments or public bodies of each country. On this principle, 769 sheets would be required to represent the land-surface of the globe, each sheet containing 5° square between the equator and 60°, and between 60° and the poles 5° of latitude and 10° degrees of longitude. The British Empire would be responsible for 222 sheets, Russia for 192, United States for 65, France 55, Scandinavia 54, China 45. Five countries would have from 20 to 30 sheets each, six more would have over 10, and ten countries would require a smaller number, Belgium, Switzerland, and Greece having only one each. One advantage of the proposed scale is that it corresponds within the limits of the shrinkage of paper with the 16 miles to an inch Survey of India maps (1 : 1013760) and with the 25 versts to an inch Russian maps (1 : 1050000).

MONGOLIA AND CENTRAL TIBET.

AT the meeting of the Royal Geographical Society on Monday Mr. W. Woodville Rockhill gave an interesting account of a journey in Mongolia and Central Tibet. Leaving Peking on December 1, 1891, Mr. Rockhill travelled to the frontier town of Kalgan, then, entering Mongolia, he passed through the pasture-lands of the Ch'ahar Mongols. After a few days spent at Kuei-hua Ch'eng, the traveller continued westward, and crossing the Yellow River on the ice at Ho-k'on, he crossed the Ordos Mongols country, and afterwards Alashan. Again entering China proper the route led through Ning-hsia, Lanchou, and Hsi-ning, the westernmost town in China, on the high road to Tibet. On March 14 Mr. Rockhill left for Tibet by an unexplored route, passing south of the Koko nor and along the foot of the mountains to the south side of the Ts'aidam, making several excursions on the way, one of special importance from the Mongol village of Shang to Tosu Nor to determine by astronomical observations the position of this sheet of water discovered by him in 1889. Mr. Rockhill's party consisted originally of five Chinese, but one had to be invalided home a few days after leaving Kumbum, and two others deserted him at Shang. He was able to hire at this place an old Chinese trader, and with these three men, assisted for a while by a Mongol and then by a Tibetan guide, he travelled till he reached China again in October, 1892. On May 27 the final start for Tibet was made from the Naichi gol in western Ts'aidam, and a general south-westerly direction was followed until July 7, when a point some 30 miles from the north-west corner of the great central Tibetan lake, called Tengri nor by the Mongols, was reached. Between the Naichi gol and the Ts'aidam the party had to endure great hardships, the great altitude ranging from 14,000 to 17,000 feet above sea-level, terrible daily snow and hail-storms, fierce winds and frequent absence of fuel, and towards the end starvation. The route, moreover, led them through vast salt marshes, bogs, and across numerous rivers, in which quicksands were frequently found. The geographical results of this portion of the journey were important. (1) The determination of the limits of the basin of the Murus (the great Yang-Tzŭ Kiang of China) and the discovery of the sources of the main branch of this river in the snow-covered flanks of the great central Tibetan range of mountains known as the Dangla. (2) The discovery of the eastern limit of the lake-covered Central Asian plateau which becomes some 600 miles west of the route Mr. Rockhill followed the Pamir, but is in the section he crossed of it called Naktsang, and sometimes, though apparently erroneously, Chang T'ang or "Northern Steppe."

Game was scarce in the great part of this region, and so wild that it could not be approached.

On July 2 the last provisions were eaten, and from that date to the 7th the party subsisted solely on tea. On the latter day a small encampment of Tibetans was reached, and a little food purchased. The next day a valley was entered dotted over with tents; it was the pasture lands of the Namru Tibetans and Lh'asa governed territory. The headman refused to give the party food unless Mr. Rockhill agreed to await the arrival of the head chief, who would decide as to whether he should be allowed to proceed southward, or be sent back to the north.

After six days' discussion with the chief and several officials from Lh'asa a compromise was effected; and Mr. Rockhill, with an escort of ten Tibetan soldiers, started eastward to reach the frontier port of Nagchuká, on the highroad to Lh'asa from the Koko nor.

On July 27 Mr. Rockhill crossed the Dangch'u and found himself on the territory of Jyadé, or "The Chinese Province," which is governed by native chiefs appointed by the Chinese Minister, resident at Lh'asa (or Lh'asa Amban). This important province was separated from Lh'asa by the Chinese in the seventeenth century, in view of the enmity existing between its people, who profess the Bonbo religion, a form of the devil worship or shamanism, though now mixed up with lamaism to such an extent, that it is hardly distinguishable from it, and the followers of the yellow and red sects of Buddhism living on Lh'asa soil.

Passing to the south of the city of Ch'amdo, to which town Mr. Rockhill, like his predecessor, Captain Bower, was refused admittance, the high road to China was reached at Pungdé (two stages south of Ch'amdo), and from this point to China a Chinese escort was given the traveller, and he was able to enjoy (!) all the luxuries of Chinese travel. Stopping at Draya, at Gartok, Bat'ang and Lit'ang, Ta-chien-lu, in Ssŭ-ch'uan, was reached on October 2. Here, on the eastern border of Tibet the journey was practically ended, for, though several thousand miles still separated Mr. Rockhill from the seaboard, they could be travelled in comfort and rapidity. Leaving Ta-chien-lu on October 5, he was in Shangai on the 29th, exactly eleven months from the time he had left it. "In that time I had travelled about 8000 miles, surveyed 3417, and during the geographically important part of the journey crossed sixty-nine passes, all of them rising over 14,000 feet above sea-level, and not a few reached 18,000. I had taken series of sextant observations at a hundred points along the road, determined one hundred and forty-six altitudes by the boiling point of water, taken three hundred photographs, and made important ethnological and botanical collections. For two months we had lived at an altitude of over 15,000 feet, soaked by the rains and blinded by the snow and hail, with little or nothing to eat, and nothing to drink but tea, and yet not one of us had a moment's illness from the day we left till we reached our homes again."

GASES IN LIVING PLANTS.[1]

PLANTS are permeated by the same gases that make up the atmosphere surrounding them: oxygen, carbon dioxide and nitrogen. Nitrogen in the form of a gas is neither used nor generated by any part of plants, unless we except the tubercles of certain roots, and so it occurs in about the same percentage inside the plant as outside of it. On the other hand, both oxygen and carbon dioxide enter into combination with, and are liberated from, the plant tissues in varying amounts at different times. The percentage of these two gases in the cavities of the plant vary through a considerable range. In a series of determinations made by Lawes, Gilbert, and Pugh, in England, the oxygen ranged from 3 to 10 per cent., and the carbon dioxide from 14 to 21 per cent. in plants which had been for some time in the dark, while plants which had been standing in sunlight reversed these figures, and gave 24 to 27 per cent. of oxygen and 3 to 6 per cent. of carbon dioxide. The two gases, therefore, bear a somewhat reciprocal relation, their sum usually being about 25 to 30 per cent. of the total gas in the plant.

The variations in the relative amount of oxygen and carbon dioxide are due to two independent processes incident to the life of plants. One of these processes is assimilation, by which all green cells of plants in the presence of sunlight, or its equivalent, such as a strong electric light, absorb carbon dioxide and liberate oxygen. This process goes on with great rapidity in healthy cells, but is entirely checked upon the withdrawal of light, or when it reaches a certain low intensity. Of course it never takes place in roots, flowers, the central portion of large stems, or other parts which are not green, nor in any fungi or other plants not possessed of green colouring matter.

The other great cause of disturbance in the relation of oxygen and carbon dioxide in the plant is the process of respiration.

Respiration in plants is essentially the same as in animals, and consists in a fixation of oxygen and the liberation of carbon dioxide. It takes place in every living cell, whatever the kind of plant, whatever the part of the plant, and whatever the conditions of active existence. The rate of respiration varies with the temperature, the age of the cell, and the nature of the chemical transformations. In normal respiration the amount of oxygen absorbed is approximately the same as the amount of carbon dioxide evolved. There are, however, certain modified forms of respiration in which this does not hold true.

If living plants be placed in a vacuum, or in an atmosphere deprived of oxygen, it is found that they can still carry on life processes for some time, accompanied with an evolution of carbon dioxide. The oxygen necessary for this process is obtained from the breaking up of compounds in the cells, and it is therefore called intramolecular breathing.

The germination of seeds, which contain a large amount of oil, is somewhat the opposite of this last process. In order to convert the fat into a more directly serviceable food material for the plant, a large amount of oxygen enters into the new combination, for which there is no equivalent amount of gas liberated. It consequently comes about that oily seeds in germinating absorb a far larger amount of oxygen than they liberate of carbon dioxide. This is known as vincular breathing.

Another variation from normal respiration is known as insolar breathing, and which, with still some other modifications, I need not stop to explain. To this brief statement of plant respiration must be added that much yet remains to be discovered regarding the details of the processes.

Assimilation and respiration are the two great causes which disturb the relative volume of the two variable gases in plants.

We shall now turn to the movement of the same two gases, oxygen and carbon dioxide. There has never been a disposition as in the case of many other plant phenomena, to explain the movement of gases upon any other than purely physical principles. We have therefore to do simply with the question of the aids and hindrances to the establishment of an equilibrium between the gases inside and outside the plant, irrespective of whether the cells are alive or dead.

It has already been stated that the relative amounts of oxygen and carbon dioxide inside the plant are usually very different, and that within a few hours the relation of the two may be completely reversed. To this may be added that the pressure of the gases inside the plant is sometimes more, sometimes less than that of the atmosphere outside the plant, almost never the same. Hales observed in his early work that a mercury gauge connected with the inside of the trunk of a tree showed an internal pressure when the hot rays of the sun warmed the trunk. This was largely due, undoubtedly, to an expansion of the gases in the trunk, by the heat. Such an excess of pressure in water plants is very common, although due to other causes. It may readily be shown by breaking stems under water, when bubbles of gas will be liberated, as undoubtedly many have noticed in gathering water lilies, or other water plants.

On the other hand, the pressure of the gas inside the plant may be less than on the outside. This has long been recognised, but was best demonstrated by Von Höhnel in 1879, to whom it occurred to cut off stems under mercury. In doing so the mercury rose to a considerable height in the vessels of the stem, and as mercury is without capillarity, this can only be ascribed to the greater pressure of the outside air, or in other words, to a partial vacuum in the plant.

An observation was made by Hales, which we may use to illustrate how such a negative pressure, as it has been called, can be brought about. He cut off a branch, fastened an empty tube to the cut end, and plunged the other end of the tube into a liquid. He found that as evaporation of moisture from the leaves took place, the liquid was drawn up into the empty tube. This phenomenon can now be explained more satisfactorily than could be done at that early day. By evaporation the liquid water inside the plant escapes in the form of vapour, and the space it occupied is filled by the gases, thus rarifying them. This rarifaction may go on in uninjured plants until the internal pressure is greatly reduced. But in the experiment, the pressure is equalised by the rise of the liquid in the tube. A later modification of Hales' experiment is to use a forked branch, place the cut end in water to give a continuous supply of moisture for transpiration, and attach the empty tube to one of the side forks of the stem, cut away for that purpose.

It is self-evident that such condensation and rarifaction of the gases in the plant could not take place if the cell walls were readily permeable to gases. Thus it comes about that one of the most important topics in connection with the movement of gases in the plant, is the permeability of tissue walls of various kinds, and especially those constituting the surface covering of plants.

I shall not attempt to conduct you through the tangle of supposition and fact, errors in experiments, correct and incorrect conclusions, and the general confusion which has come from the labours of physicists, chemists and botanists for the last twenty-five years, during which the subject has received particular attention. The results of the later work have been to cast grave doubts upon the correctness, or at least the interpretation of some of the experiments most relied upon heretofore. Nevertheless many points still lie open for verification, and untouched parts of the subject await investigation.

In the earlier days it was found that the leaves and young stems of plants have their epidermis more or less well supplied with minute openings, called stomata, or breathing pores, which communicate with small air cavities inside, which in turn branch out among the cells into a network of minute passages rarifying throughout the plant. This intricate network of intercellular passages affords an air communication throughout the whole plant, and connects directly with the outside atmosphere through the stomata. Subsequent to the discovery of stomata, it was ascertained, that in stems more than one year old, the stomata are replaced by another kind of opening, known as lenticels, which in some form are doubtless to be found in the bark of shrubs and trees of whatever age.

Gases stream into and out of the plant through the stomata and simpler lenticels, according to the law governing the movement of gases through minute openings in thin plates. The rate of movement is accordingly proportional to the square roots of the density of the mixing gases. Such a movement of gases is known as effusion.

The movement by which gases pass from one part of the plant to another, through the intercellular spaces, is governed by other laws. It was at first thought that the rate of movement would correspond to that in capillary tubes, according to the well-known law of Poisenille, that it is proportional to the fourth power of the diameter, divided by the length of the tube. But upon testing the matter two years ago, Wiesner found that owing to the extreme minuteness of the intercellular spaces, and their zigzagged and branched condition, this law does not hold, neither does the movement prove to be proportional to the density of the gases. The discovery of the law of the rate of movement of gases in intercellular spaces, that is, the transpiration of gases, is, therefore, yet to be discovered, together with other interesting facts pertaining to the subject. Poisenille's law does, however, hold good for the movement of gases in the woody ducts, but here it is of limited application, for these do not connect with one another, with the intercellular spaces, or with the exterior of the plant.

---

[1] Reprinted from the *American Naturalist* for February.

The walls of most cells, ducts, and surface covering of plants, except as already mentioned, are imperforate, that is without any openings that can be demonstrated by the microscope. If gases pass through them, it must be in accordance with some law of diffusion, or osmosis. Many experiments in this line have been tried, and the results have been of the most diverse character. It is impossible to give a fair idea of the subject in the time at my disposal, and it must suffice to mention a few bare facts.

The most astonishing and important results were obtained by Wiesner, in experiments conducted at Vienna, two years since. It would be a most natural interpretation, it seems to me, to think that the gases are forced from one cell to another, through the cell walls by differences in pressure. Wiesner found, however, that it is impossible to force gases through cell walls of any kind whatever, by any pressure they will stand, acting for any length of time. For instance, a bit of grape skin held up a column of mercury, 70 centimetres high, for seventy-five days, and a piece of cherry skin withstood a pressure of 3 atmospheres for twenty-four hours. Similar experiments were tried with cuticularised, suberised, liquefied and simple cellulose tissues from many sources, and with uniformly the same results, whether the tissues were moist or dry, alive or dead.

But in the same set of experiments it was found that if gases cannot be forced through cell walls, they will readily pass through by simple osmotic diffusion. All cells permit the passage of gases by diffusion when moist, dependent upon the coefficient of absorption and the density of the gas. Cuticular and corky formations also permit the passage of gases when dry. Thus we see that gases may be forced through the stomata, or breathing pores, by varying pressure, but can only pass through the epidermis and bark of plants by diffusion. We therefore arrive at the conclusion that the gases inside and outside of the plant are brought to an equilibrium by direct interchange through the stomata and intercellular spaces, aided by the comparatively slow process of diffusion through the whole surface of the plant, both above and below ground.

J. C. ARTHUR.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The Curators of the Hope Collections will proceed to the election of a Hope Professor in Trinity Term 1893. Candidates for the Professorship, of which the emoluments are £480 per annum, are required to send in their applications, together with such evidence of their qualifications as they may wish to submit to the Curators, on or before May 1, 1893, to the Registrar of the University, Clarendon Buildings, Oxford. The duties of the Hope Professor are, to give public lectures and private instruction on zoology with special reference to the Articulata, to arrange and superintend the Hope collection of annulose animals, and to reside in the University for the term of eight months in every academical year between October 1 and July 15.

Physiological Department.—It is satisfactory to note that the number of students in this department is greater than in any previous corresponding term. The increase is due not only to the larger number of candidates for the M.B. degree, but also to a larger number of candidates for honours in Physiology in the Honour School of Natural Science. The course of study during the term has comprised lectures on the general subjects of the Honour School by the Waynflete Professor on the physiology of nutrition, by Dr. J. S. Haldane; and on the nervous System, by Dr. E. Starling. Mr. Leonard Hill has undertaken the course of lectures on elementary physiology. Practical instruction has been carried on under the superintendence of Dr. Haldane and Mr. M. S. Pembrey.

SCIENTIFIC SERIALS.

Bulletin of the New York Mathematical Society, Vol. ii. No. 4 (New York, 1893).—The contents of this number are an abstract of a paper (read before the Society, June 4, 1892) by Prof. W. Woolsey Johnson, entitled "On Peters's Formula for Probable Error" (pp. 57–61). A clear abstract of Engel and Sophus Lie's Theorie der Transformationsgruppen, by C. H. Chapman (pp. 61–71), and a similar account of U. Dini's work on the theory of functions of a real variable, by J. Harkness (pp. 71–76). Notes and new publications complete the number.

Bulletin de l'Académie Royale de Belgique, No. 12.—An unpublished corollary of Kepler's laws, by F. Folie. A deduction of Dewar's empirical formula for the ratios of the mean velocities of the planets from Kepler's third law.—On the common cause of surface tension and evaporation of liquids (preliminary note) by G. Van der Mensbrugghe. The author endeavoured to show in 1886 that the particles of a liquid are at distances apart which increase as we approach the surface, and that therefore the tension is greatest at the surface. Following up this view, he regards surface tension as the elastic force due to tangential displacement of surface particles, and evaporation as produced by molecular displacement beyond a certain limit in a direction normal to the surface. He predicts that a liquid of high surface tension will be able to evaporate across another liquid which has a lower density and surface tension, and does not mix with the former.—On a new optical illusion, by M. J. Delbœuf.—On the reduction of invariant functions in the system of geometric variables, by Jacques Deruyts.—Construction of a complex system of straight lines of the second order and the second class, by François Deruyts.—Contribution to the study of diastase, by Jules Vuylsteke.—Pupine, a new animal substance, by A. B. Griffiths.—Two experimental verifications relative to refraction in crystals, by J. Verschaffelt. Billet has calculated that if refraction takes place on a cleavage face of a crystal of Iceland spar, the angle of refraction for the extraordinary ray corresponding to normal incidence is 6°12′, and that the ray is normal with an incidence of 9° 49′. M. Verschaffelt has determined these angles experimentally, and found them to be 6° 9′ and 9° 45′ respectively, thus showing a close agreement with the theoretical values.—On the bacterian fermentation of sardines, by M. A. B. Griffiths.—On prejudices in astronomy, by M. F. Folie.—On the constitution of matter and modern physics, by P. de Heen.

Ann. dell' Ufficio Cent. Meteor e Geodinamico, ser. secund., part iii. vol. xi. 1889. Roma, 1892.—Fumo di Vulcano veduto dall' Osservatorio di Palermo durante l'eruzione del 1889, by A. Ricco.—From the obervatory terrace (72m. above sea level) the summits of some of the Lipari islands are visible, but that of Vulcano (140km. distant) is not so. Any smoke or vapour that exceeds 300m. in height can, however, be seen. The author was not successful in either photographing or measuring the dimensions of the smoke cloud, which were, however, estimated by comparison with the size of Alicuri, which had been carefully determined. At the commencement of the observations (January 6, 1889) the smoke column reached a height 10½km. and had the form of the pine tree. Several drawings are given, and the form assumed in some cases is very curious. The paper terminates with some thermodynamical calculations, which are very interesting, but unfortunately based on false premises. The author supposes that the eruption was caused by the access of the sea-water. He supposes this to be at sea level, and calculating the pressure at this point, concludes the vapour was produced from water heated to 196° C. only. He seems to be unacquainted with the solution of H_2O in the fluid volcanic glass, the vesiculation and escape of vapour from it, involving so many data with which the physicist has not yet supplied us, as to make any calculations of such a nature of a highly romantic rather than of practical use.

Mem. Soc. degli Spettroscopisti Ital. vol. xxi. 1892.—La Grandissima Macchia Solare del Febbrajo 1892, by A. Ricco.—This memoir is a description of an enormous sun-spot which developed from some small ones that had been noticed during three rotations before January 17. On February 5, they made their grand entry on the solar face on the east side, and by the 7th could be seen by the eye aided only by a smoked glass. The whole spot was composed of a very large one surrounded by smaller ones, and composed of great tongues of flame extending in towards the nucleus, sometimes arranged in a spiral manner. It attained its maximum on February 11, when the whole patch measured, in earth diameters, as follows: Total length, 20; total breadth, 8; the more compact extended 8 in each direction. After this the breaking up of the spot proceeded at a rapid rate, and by rotation the spot passed out of sight on the 18th. On the next rotation the diminution was much more marked. The author gives six observations of latitude, eight drawings, and several spectroscopic observations on the flames.

SOCIETIES AND ACADEMIES.

London.

Royal Society, February 23.—"On the Mimetic Forms of certain Butterflies of the Genus *Hypolimnas.*" By Colonel C. Swinhoe, M.A. Communicated by Prof. E. Ray Lankester, F.R.S.

The object of this investigation is to study the changes undergone by the species of a small group of butterflies as they are traced from one locality to another, and to ascertain the bearing of these facts upon the theory of mimicry.

We find the representatives of the Indian *Hypolimnas bolina* in a long list of localities in Malaya, Polynesia, and Africa: the local representatives differ from each other and from the Indian form, but they agree in possessing in one or both sexes a more or less superficial resemblance to some conspicuous species belonging to a specially defended group and inhabiting the same locality; the same is true of the three forms of the female of *Hypolimnas misippus.*

The facts afford the most convincing evidence of the truth of the theory of mimicry enunciated by H. W. Bates.

The study of these numerous but closely-related forms belonging to the genus *Hypolimnas* also throws light upon such interesting questions as:—

(1) The special liability of the female to become mimetic.

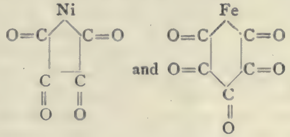
(2) The ancestral form from which the various mimetic varieties have been derived.

(3) The mimetic resemblance to different species in the same locality.

(4) The divergent conditions under which mimicry appears in closely-related species.

(5) The relation between selection and variation in the production of mimetic resemblance.

Physical Society, February 10.—Annual general meeting.—Mr. Walter Baily, Vice-President, in the chair.—The reports of the Council and Treasurer were read and approved, copies of the balance-sheet being distributed to members. From the former it appears that the society now numbers 371 ordinary members and 12 honorary members, and during the past year the society has lost six members by death, viz. the Rev. T. Pelham Dale, Dr. J. T. Hurst, B. Loewy, C. E. Walduck, G. M. Whipple, and P. W. Willans. Obituary notices accompany the report.—The treasurer's statement shows the financial condition of the society to be satisfactory. A cordial vote of thanks to the Committee of Council on Education for the use of the rooms and apparatus of the Royal College of Science was proposed by Mr. Shelford Bidwell, seconded by Mr. Blakesley, and carried unanimously. A similar vote was accorded to the auditors, Mr. H. M. Elder and Mr. A. P. Trotter, on the motion of Dr. Gladstone, seconded by Prof. S. P. Thompson. Prof. Ramsay proposed a vote of thanks to the officers of the society for their services during the past year; this was seconded by Prof. Fuller, and carried. Prof. Perry responded. The following gentlemen were declared duly elected to form the new council:—President: Prof. A. W. Rücker, F.R.S. Vice-Presidents: Walter Baily, Major-General E. R. Festing, F.R.S.; Prof. J. Perry, F.R.S.; Prof. S. P. Thompson, F.R.S. Secretaries: H. M. Elder, 50, City Road, E.C.; and T. H. Blakesley, 3, Eliot Hill, Lewisham, S.E. Treasurer: Dr. E. Atkinson, Portesbery Hill, Camberley, Surrey. Demonstrator: C. Vernon Boys, F.R.S., Physical Laboratory, South Kensington. Other members of Council: Shelford Bidwell, F.R.S., W. E. Sumpner, Prof. G. Fuller, J. Swinburne, Prof. J. V. Jones, Rev. F. J. Smith, Prof. G. M. Minchin, L. Fletcher, F.R.S., Prof. O. Henrici, F.R.S., James Wimshurst.—In response to invitations for suggestions regarding the working of the society, Prof. S. P. Thompson said all must appreciate the efforts of the late Council, and particularly of the honorary secretaries, in making the society better known. But he could not help thinking that there were many persons amongst teachers of physics and scientific amateurs whose active sympathies it was desirable to engage, who were not yet associated with the society. Perhaps the time of meeting was not convenient for all, but he thought much might be done by freely circulating particulars of what was going on at the meetings. The daily papers merely announced the meetings, but said nothing as to the place of meeting or the papers to be read. In his opinion the society did not take the position in the scientific world to which it was entitled, and he wished to inspire members with a determination to bring its claims prominently forward.—Mr. Blakesley pointed out that almost all the scientific and technical papers gave full announcements of the meetings and of the papers to be read.—Mr. W F. Stanley said Friday afternoon was not convenient for scientific men engaged in trade.—The meeting was then resolved into an ordinary science meeting.—Dr. J. H. Gladstone, F.R.S., read a paper on some recent determinations of molecular refraction and dispersion. The paper relates to the new metallic carbonyls, the metals indium and gallium, sulphur, and to liquefied oxygen, nitrous oxide, and ethylene. The carbonyls were found to be extremely refractive and enormously dispersive. For iron pentacarbonyl, $Fe(CO)_5$, the molecular refraction for the line α of hydrogen was found to be about 68·5, and the molecular dispersion between γ and α of hydrogen 6·6. For nickel tetra-carbonyl, $Ni(CO)_4$, the corresponding numbers are 57·7 and 5·93. In discussing the results it was pointed out that if the molecular refraction of CO be taken as 8·4, the value expected in organic substances, then the atomic dispersions of nickel and iron come out greatly in excess of the known values as determined from solutions of their salts. The author considers the most probable explanation of the excessive refractions and dispersions of the carbonyls is to be sought in the peculiar arrangement of the CO, and on optical as well as chemical grounds accepts the ring formulæ indicated by Mr. Mond in his lecture at the Royal Institution, viz.:—



On this supposition the molecular refraction of CO comes out 11·9 from the nickel compound and 11·3 from the iron ore, whilst the molecular dispersion (γ—α) is about 1·3 in each case. For indium and gallium the atomic refractions calculated from latest data are 13·7 and 11·6 respectively. Sulphur has been examined in the states of solid, liquid, and gas, and also in simple chemical combination and in solution, all the resulting numbers for its atomic refraction being remarkably concordant. For the line C this is about 16. The dispersions in all the different states are also in close agreement. Numbers relating to carbon and chlorine are also given. The specific refractions of oxygen, nitrous oxygen, and ethylene in the liquid states had been recently determined by Profs. Liveing and Dewar. For liquid oxygen the refraction equivalent (3·182) differs little from that deduced from gaseous oxygen at ordinary temperatures (3·0316), and also corresponds fairly closely to the 3·0 obtained by Landolt from organic compounds. Liquid nitrous oxide gave 11·418 and 11·840 as the molecular refractions for the red ray of lithium and the line G respectively. In discussing these numbers it was pointed out that nitrogen in nitrous oxide was not in the same condition as nitrogen in ammonia. The latest determinations with liquid ethylene gave the molecular refraction for the line A as 17·41, the theoretical value being 17·40, thus showing very close agreement.—Mr. E. C. C. Baly made a communication on separation and striation of rarefied gases under the influence of the electric discharge.

Chemical Society, February 3.—Dr. W. H. Perkin, Vice-President, in the chair. The following papers were read:—The connection between the atomic weight of the contained metals and the magnitude of the angles of crystals of isomorphous series, by A. E. Tutton. The author has made a detailed goniometrical investigation of twenty-two salts belonging to the $R_2M(SO_4)_2,6H_2O$ series of double sulphates containing as the alkali metal R potassium, rubidium or cæsium, and as the dyad metal M magnesium, zinc, iron, manganese, nickel, cobalt, copper, or cadmium. On classifying the salts into three groups according to the alkali metals which they contain, it is found that the geometrical and other properties of the salts containing rubidium as the monad metal, lie between those of the corresponding potassium and cæsium salts. Thus the cæsium salts show the greatest power of crystallising, those of potassium the least, whilst the salt containing rubidium occupy an intermediate position in this respect. Similar behaviour is observed with regard to the crystalline habits of the various salts; each of the three groups is characterised by the possession of a distinctive habit. The crystalline habit of the salts containing potassium is widely different from that of the salts containing cæsium; the specific characteristic habit of the rubidium salts is of an intermediate nature. There is a difference of some two degrees or so between the axial angles (β) of the potassium and cæsium salt crystals containing the same dyad metal; the magnitude of the angle β in the corresponding rubidium salt is approximately the mean of these two. The differences between the axial angles are hence approximately proportional to the differences between the atomic weights of the contained alkali metals if the dyad metal remain the same. The magnitudes of all the angles between the faces of the crystals of the salts of this series containing rubidium as the alkali metal lie between, though not ordinarily midway between, the magnitudes of the corresponding angles upon the crystals of the potassium and cæsium salts containing the same dyad metal. The alkali metals exert a preponderating influence upon the geometrical form of the crystals, the magnitudes of the angles being altered on displacing one alkali metal R by the next higher or lower to an extent attaining a maximum, in certain angles, of more than a degree, whilst the displacement of the dyad metal M by any other of the same group is unattended by any material change in the angular magnitudes.—The preparation of phosphoric oxide free from the lower oxide, by W. A. Shenstone and C. R. Beck. Phosphoric oxide may be freed from the lower oxides by distilling it over platinum sponge in presence of excess of oxygen.—Contributions to our knowledge of the aconite alkaloids: Part iv., on isaconitine (napelline), by W. R. Dunstan and E. F. Harrison. The authors have examined the alkaloid isaconitine $C_{33}H_{45}NO_{12}$, which occurs together with its isomeride aconitine in the roots of *Aconitum napellus*. It is present to as great an extent as aconitine, and is obtained in the pure state as a colourless, friable, varnish-like mass. Its alcoholic solution is feebly dextrorotatory. The salts somewhat resemble the corresponding aconitine salts in physical properties. On attempting to prepare an aurichloride, aurochlorisaconitine, $C_{33}H_{44}(AuCl_2)NO_{12}$, results. Isaconitine is gradually hydrolysed by mineral acids or water yielding the same products as does aconitine, viz. aconine and benzoic acid

$$C_{33}H_{45}NO_{12} + H_2O = C_{26}H_{41}NO_{11} + C_7H_6O_2.$$

Whilst aconitine is a most violent poison, even in excessively minute doses, relatively large quantities of isaconitine must be administered to small animals in order to produce a toxic effect, which effect is the result of a physiological action in the main distinct from that of aconitine. It seems doubtful whether isaconitine would prove toxic to man, except when given in very large doses.—Contributions to our knowledge of the aconite alkaloids: Part v., the composition of some commercial specimens of aconitine, by W. R. Dunstan and F. H. Carr. The great differences in toxic power exhibited by different samples of aconitine have led the authors to examine sixteen specimens of "aconitine from *A. napellus*." Most of the samples were amorphous; these contained little or no aconitine, but were chiefly composed of aconine, isaconitine, and homoisaconitine, all of which appear to be very slightly, if at all, toxic. Of the crystalline specimens examined, only two were pure, most of them being contaminated with more or less amorphous alkaloid. Hence it is not surprising that great differences have been observed in the mode of action and toxic power of commercial "aconitine."—Synthesis of oxazoles from benzoin and nitriles, by F. R. Japp and T. S. Murray. The authors find that nitriles and benzoin interact with elimination of water when a mixture of the two compounds is dissolved in concentrated sulphuric acid, an oxazole being formed in which the hydrocarbon radicle attached to the cyanogen of the nitrile occupies the *meso*-position. Thus acetonitrile yields in this manner $\alpha\beta$-diphenyl-μ-methyloxazole

$$\begin{array}{l}Ph.CH.OH\\ \quad|\\ Ph.CO\end{array} + NC.Me = \begin{array}{l}Ph.C.O\\ \quad\|\\ Ph.C.N\end{array}\!\!\!\!> C.Me + H_2O.$$

A number of instances of this reaction are cited. The above oxazole, when treated with ammonia, is converted into the corresponding imidazole identical with Japp and Wynne's methyldiphenylglyoxaline.—The action of nitrosyl chloride and of nitric peroxide on some members of the olefine series, by W. A. Tilden and J. J. Sudborough. Ethylene dichloride alone results from the interaction of ethylene and nitrosyl chloride. Propylene and butylene yield with nitrosyl chloride a mixture of dichloride and nitrosochloride, whilst trimethylene (amylene) is almost entirely converted into nitrosochloride.—Piperazine, by W. Majert and A. Schmidt. The authors correct certain erroneous statements regarding the physical and chemical characters of piperazine. They have prepared the following series of hydrates of piperazine, the hexhydrate, which crystallises from dilute aqueous solutions, being the most readily formed:—

$C_4H_{10}N_2$, H_2O	m.	p.	75°
,, , $2H_2O$	,,	,,	56°
,, , $3H_2O$	,,	,,	39-40°
,, , $4H_2O$	,,	,,	42 43°
,, , $5H_2O$	,,	,,	45°
,, , $6H_2O$	,,	,,	48°

Linnean Society, February 16.—Prof. Stewart, President, in the chair.—Mr. Clement Reid exhibited and gave an account of some seeds of *Paradoxocarpus carinatus*, an extinct Pliocene and Pleistocene plant from the Cromer fossil bed. Mr. Reid also exhibited and described some examples of *Potamogeton headonensis*, a new type of pond weed from the Oligocene strata of Hordle Cliff in Hampshire. His remarks, which were listened to with great interest, were elucidated with the aid of diagrams, and were criticised by Mr. W. Carruthers and others.—Mr. J. E. Harting exhibited some dried plants of a so-called Greek tea (*Sideritis theezans*, Boissier), which during a recent visit to Thessaly he had found to be extensively used there, as an infusion in lieu of tea. He also exhibited some photographs of Thessalian scenery, showing the geological and botanical character of the country bordering the great plain of Larissa.—Dr. Otto Stapf pointed out on the map the scene of Bornmueller's recent botanical explorations in Persia, and gave some account of the flora of that region as far as has at present been ascertained.—On behalf of Mr. C. B. Plowright, a paper, communicated by the President, was read on the life history of the Æcidium on *Paris quadrifolia*.—On behalf of Mr. J. C. Willis, who was unfortunately prevented by illness from attending, a paper was read entitled "Contributions to the natural history of the flower." This paper, the first of a series, dealt with the fertilisation by insects of plants belonging to the genera *Claytonia*, *Phacelia*, and *Monarda*.—Some observations on British worms, by the Rev. H. Friend, were read on his behalf by the Secretary.

Royal Meteorological Society, February 15.—Dr. C. Theodore Williams, President, in the chair.—The following papers were read:—Report on the phenological observations for 1892, by Mr. E. Mawley. The Royal Meteorological Society has for a number of years past collected observations on natural periodical phenomena, such as the date of the flowering of plants, the arrival, song, and nesting of birds, the first appearance of insects, &c. These observations were supervised and discussed by the Rev. T. A. Preston until 1888, since which time they have been under the direction of Mr. E. Mawley. The year 1892 was on the whole very cold and backward. The frequent frosts and dry weather during the first five months greatly retarded vegetation, and consequently all the early wild flowers were very late in coming into blossom. Bush fruits and strawberries were, as a rule, good and fairly plentiful. Plums and pears were almost everywhere a failure, and apples were considerably under the average. The wheat crop was a very light one, owing in part to the attacks of blight brought on in many places by the frost in June. Oats, beans, and peas were much under the average, while barley was the chief crop of the year. Potatoes, turnips, and mangolds were above the average. During August butterflies were very numerous, the clouded yellow butterfly being exceptionally abundant.—Relation between the duration of sunshine, the amount of cloud, and the height of the barometer, by Mr. W. Ellis. This is a discussion of the observations made at the Royal Observatory, Greenwich, during the fifteen years 1877-91, from which it appears that in the months from February to October there is, on the whole, a distinct probability of increased sunshine and correspondingly less cloud with increase of barometer reading. The winter in all conditions of the barometer is uniformly dull. Mr. Ellis says that it is evident that high barometer in summer presages increased sunshine, that the effect is less pronounced in early spring and late autumn, and that it becomes slightly reversed in winter.—Winter temperatures on mountain summits, by Mr. W. Piffe Brown. In this paper the author gives the lowest winter temperature on the summit of Y Glyder fach, four miles E.N.E. from Snowdon, and 3262 feet above sea level, as recorded by a minimum thermometer during the last twenty-five years. The lowest temperature registered was 9° during the winter 1891-2.

Zoological Society, February 14.—Osbert Salvin, F.R.S., Vice-President, in the chair.—The secretary read a report on the additions that had been made to the Society's menagerie during the month of January 1893.—Prof. G. B. Howes exhibited and made remarks on an abnormal sternum of a Marmoset (*Hapale iacchus*) in which the mesosternal elements of the opposite sides were distinct, and alternately disposed, and discussed its probable bearings upon the sternum of the Anthropomorpha, particularly as represented by the orang.—Prof. T. Jeffrey Parker, F.R.S., read a paper on the cranial osteology, classification, and phylogeny of the *Dinornithidæ*. The author gave a detailed description of the skull in various genera and species of Moa, founded upon the examination of more than 120 specimens. A detailed comparison with the skulls of the other Ratitæ followed, as well as an extensive series of measurements.—The bearing of the facts ascertained upon the classification of the family was discussed. The author recognised five genera of *Dinornithidæ*, arranged in three subfamilies as follows: Subfamily DINORNITHINÆ, genus *Dinornis*; subfamily ANOMALOPTERYGINÆ, genera *Pachyornis*, *Mesopteryx*, and *Anomalopteryx*; subfamily EMEINÆ, genus *Emeus*. The phylogeny of the group was then discussed. *Mesopteryx* was considered to be the most generalised form, while *Dinornis* and *Emeus* were both highly specialised, but in different directions. Of the other Ratitæ, *Apteryx* came nearest to the Moas in the structure of its skull, and strong affinities were shown to the New Zealand genera by *Dromæus* and *Casuarius*. *Struthio* and *Rhea*, on the other hand, showed no special affinities, so far as the skull is concerned, either to the Australasian forms or to one another.—Mr. R. Lydekker read a paper on the presence of a distinct coracoidal element in adult sloths, and made remarks on its homology. It was shown that in two skeletons of sloths in the British Museum the shoulder-girdle exhibited a distinct coracoidal element. This element, like the coracoid process of the human scapula, was correlated with the precoracoid of the lower vertebrates; and the question was then discussed as to the name by which it should properly be called.—A communication was read from Dr. G. Radde, containing an account of the present range of the European bison in the Caucasus.

OXFORD.

Junior Scientific Club, Feb. 17.—In the Morphological Laboratory.—The President in the chair.—Mr. A. L. Still gave an exhibit of a variety of a common pheasant, which was shot near Croydon. This proved to be an extremely light-coloured young cock.—Mr. H. Balfour gave an exhibit of some modern Klepsydræ, such as are now used in guard rooms in many parts of Northern India and Burmah. He also showed some water clocks from Burmah, one of which was of interest as having come from the Imperial Palace of Mandalay, where it was the public standard of time.—Dr. Leonard Hill read an account of his researches on the gas evolved from muscles.—Mr. H. V. Reade read a paper on consciousness, and the unconscious, citing several cases of dual personality, and showing that memory could be explained by purely physiological reasoning.

EDINBURGH.

Royal Society, February 6.—Sir Arthur Mitchell, K.C.B., Vice-president, in the chair.—Mr. John Aitken read a paper on the particles in fogs and clouds. In a paper read some time since on the water particles in clouds, Mr. Aitken came to the conclusion that there was a relation between the density of the clouds and the number of water particles present. In May last year he made further observations, and got results opposite to the former. Instead of the density being nearly proportional to the number of water particles present, it was much short of proportionality, and the particles were small in size. Mr. Aitken points out that the size of the particles of water changes with the age of the clouds, and concludes that his first observations were made upon old clouds, while the latter series were made upon newly-formed clouds. He also considered the question of the persistence of fog-particles. There are two kinds of fog. In one the particles tend to persist, in the other they do not. That is, in one case, change of size of the particles takes place rapidly; in the other it does not. In town fogs it is not so much the number of dust particles that is of importance as their composition. If town dust were composed of particles having an affinity for water the fogs would have shorter duration.—Sir Douglas Maclagan described and explained an apparatus designed by Mr. J. Buchanan Young, Public Health Laboratory, Edinburgh University, for counting bacterial colonies in roll cultures.—A note, by Prof. Anglin, on properties of the parabola, was read.—Mr. A. J. Herbertson read a preliminary note on the hygrometry of the atmosphere at Ben Nevis. He finds that the observations already made agree well with the formula $y = a x + b w + c$; where y is the difference between the readings of the dry and wet bulbs, x is the temperature of the dry bulb, w is the weight of moisture per litre, and a b c are constants.

DUBLIN.

Royal Dublin Society, January 18.—Prof. W. J. Sollas, F.R.S., in the chair.—Dr. J. Joly, F.R.S., read a paper on the cause of the bright colours of Alpine flowers. The conditions of insect life upon the higher Alps are referred to in this paper as bearing upon the question. Observations made by the author show that many thousands of bees and butterflies frequently perish in the cold of night-time on Swiss glaciers and firns. The author advocates the view that the scarcity of fertilising agents promotes a struggle for existence in the form of a rivalry to attract the attention of the fewer fertilisers by vivid colouring.—Prof. G. A. J. Cole read a paper on *Hemitrypa hibernica*, M'Coy.—A paper was read on a suggestion as to a possible source of the energy required for the life of bacilli, and as to the cause of their small size, by Dr. G. Johnstone Stoney, F.R.S., Vice-President.—Prof. W. J. Sollas, F.R.S., read a paper on the law of Gladstone as an optical probe.

February 22.—Prof. W. J. Sollas, F.R.S., in the chair.—Mr. Thomas Preston read a lecture note on the principle of work, showing that since the virtual work of a force is equal to the movement of an equal force at right angles to it, the principle of virtual work follows immediately as a corollary to the theorem of movements.—Prof. D. J. Cunningham, F.R.S., communicated a paper by Prof. A. M. Paterson on the human sacrum.—Prof. A. C. Haddon communicated a paper by Miss Florence Buchanan on *Eunice phylocorallia*, n. sp., commensal with *Lophohelia prolifera*.

PARIS.

Academy of Sciences, February 20.—M. de Lacaze-Duthiers in the chair.—Description of an instrument to show the small variations in the intensity of gravitation, by M. Bouquet de la Grye. The instrument, which has been set up in a cellar of the Dépôt de la Marine, consists of an iron tank containing hydrogen confined over mercury, with three tubes leading out through the bottom. Two of these tubes are bent upwards to about 40 cm. above the ground. One of them is used for filling the tank with mercury, the other for letting in the hydrogen, which is accomplished by letting mercury run out through the third pipe at the bottom. The second pipe ends in a horizontal tube made of glass, through the walls of which the fluctuations of the column of mercury sustained by the elastic force of the hydrogen can be observed. By means of an alcohol thermometer immersed in the mercury on the top of the tank, changes of temperature of one-thousandth of a degree are indicated by a movement of 1 mm. The column oscillates with each change of temperature and each variation of gravitation, but is not affected by changes of pressure, since the tube is kept closed at the top. Under these circumstances, the instrument in question is capable of indicating the change of gravitational force due to the change in the position of the moon by a displacement of 0·46 mm. The apparatus is difficult to set up, and will require some improvement before it can give trustworthy results.—Observation on the conditions which appear to have obtained during the formation of meteorites, by M. Daubrée. The heterogeneous structure of meteorites, the innumerable iron granules disseminated through the stony matrix, so different from the well-defined and voluminous crystals obtained by the fusion of the constituent minerals in the laboratory, and M. Stanislas Meunier's success in imitating meteorites by means of gaseous reactions, lead to the conclusion that they have not been produced by fusion, but by a sudden precipitation of different gases into the solid state.—On the preparation of uranium at a high temperature. Rapid preparation of chromium and manganese at a high temperature, by M. Henri Moissan (see Notes).—On stereochemistry, by M. C. Friedel.—On the benzoates and metanitro-benzoates of diazoamidobenzene and para-diazoamidotoluene, by MM. A. Haller and A. Guyot.—High atmospheric pressures observed at Irkutsk from January 12 to 16, 1893, by M. Alexis de Tillo. During four days the barometer remained above 800 mm., and on January 14 the highest value known up to the present, 807·5 mm., was reached, the temperature being − 46°·3 C.—M. Callandreau was elected Member in the place of the late Admiral Mouchez; and M. Kékulé Correspondent in the place of the late M. Stas.—Summary of solar observations made at the royal observatory of the Roman College during the last quarter of 1892, by M. P. Tacchini.—On the terms of the second order resulting from the combination of aberration and refraction, by M. Folie.—On the essential singularities of differential equations of a higher order, by M. Paul Painlevé.—Remarks on the preceding communication, by M. É. Picard.—On uniform integrals of linear equations, by M. Helge von Koch.—Generalisation of Lagrange's series, by M. E. Amigues.—On the part played by the steam jacket in multiple expansion engines, by M. A. Witz.—A direct-reading stereo-collimator, by M. de Place.—Hysteresis and dielectric viscosity of mica for rapid oscillations, by M. P. Janet. A comparison of differences of potential and resulting charges during rapid oscillations, determined by means of the apparatus described last year, reveals a lagging of the charge behind the potential, both increasing and decreasing, and a curve plotted with the values obtained for a mica condenser suggests some analogy with Ewing's curves of magnetic hysteresis.—Optical field, absolute, and relative field of view of the human eye, by M. C. J. A. Leroy.—On the achromatism of semicircular interference fringes, by M. G. Meslin.—A new system of atomic weights, partly founded upon the direct determination of molecular weights, by M. A. Leduc.—Decomposition of the alkaline aluminates by carbonic acid, by M. A. Ditte.—On mixtures of ether and water, by M. L. Marchis.—On the heat of formation of arragonite, by M. H. Le Chatelier.—On the crystalline forms of chromium and iridium, by M. W. Prinz.—Ammoniacal fermentation of earth, by MM. A. Muntz and H. Condon.—On the composition of the salts employed as condiment by the people about the Oubangui, by MM. J. Dybowski and Demoussy.—Oxyhæmatine, reduced hæmatine, and hæmochromogen, by MM. H. Bertin-Sans and J. Moitessier.—On the histological alterations of the cerebral cortex in certain mental diseases, by M. R. Colella.—On the structure and growth of the calcareous shell of the barnacle (*B. tintinnabulum*), by M. Gruvel.—On the causes of the green colour of oysters, by M. S. Jourdain.—Geological remarks on the diamond-bearing meteoric irons, by M. Stanislas Meunier.

AMSTERDAM.

Royal Academy of Sciences, January 28.—Prof. van de Sande Bakhuysen in the chair.—Mr. Kapteyn dealt with the distribution of stars in space. It has been long known that the mean proper motion in the galaxy is smaller than elsewhere. A thorough investigation of the proper motion of *all* the stars of the Draper catalogue observed by Bradley in both co-ordinates (2357 stars) shows, that this fact is due to an excess of insensible or very small proper motion in the milky way. Those exceeding 0″·055 show no aggregation towards that zone. As far as the evidence goes, it further proves, by means of the angle subtended by the solar motion in space, that stars with equal proper motion *in* and *out* of the galaxy have nearly equal distances. These two facts taken together prove that Struve's theory of the arrangement of the stars in space must be abandoned. In order to find what arrangement must be substituted Mr. Kapteyn has considered the stars of the first and second spectral type separately, and arrives at the conclusion that the latter are very strongly condensed about a centre not far from our system, approximately in the direction of 0h. R.A. and +42° of decl., whilst the stars of the first type are more nearly evenly distributed in the proximity of our sun. Notwithstanding this difference in arrangement Mr. Kapteyn thinks that probability points to the conclusion that the two types belong to one and the same system:—(1) Because the centre of condensation of the second type stars coincides very nearly with the apparent centre of the milky way (which seems to consist mainly of first type stars). (2) Because the stars with *insensible* proper motion of *both* types are strongly condensed towards the plane of the milky way. (3) Because groups of stars, which undoubtedly form stellar systems (*e.g.* Hyades) contain stars of both types.—Mr. van Bemmelen, in pursuing his inquiry on colloidal hydrates, spoke at the meetings of November 26, 1892, and of January 28, 1893, on the constitution and composition of the hydrogels of S_1O_2 and of CuO, as these result from his determinations of their tension of vapour (at 15°), changing in a continuous way with their tenure of water.—Mr. Kamerlingh Onnes showed the isodynamics of a new physical laboratory at Groningen, mapped under Prof. Haga's direction with the localvariometer by Mr. Wind, proving the excellent constancy of the magnetic field. A new theory of the localvariometer points to another ratio of distances of the deflecting magnet-pairs than that given by Kohlrausch as preferable.—Mr. Schoute treated of "the uniform representation of a cubic surface on a plane." Indication of the number of points common to two curves on F^3, the plane representations of which are given. Application as to the position of the twenty-seven lines with respect to one another.

THEORY OF THE SUN.

Théorie du Soleil. By A. Brester, Jz., Docteur ès Sciences. (Amsterdam: Johannes Müller, 1892.)

DR. BRESTER'S preliminary account of his new theory of the sun has already been noticed in our columns (NATURE, vol. xxxix. p. 492). The present volume is a communication to the Amsterdam Academy of Sciences, and gives a complete statement of the principles and their application to the various solar phenomena. The author is careful to point out that he has not contributed a single fact of observation himself, but is content to rely on the work of others. Nevertheless, he is evidently a most careful student, and if his theory cannot be accepted, some of its points are well worth the attention of solar physicists.

Starting with the sun as a mass of incandescent vapours, it does not seem unreasonable to regard, with Dr. Brester, the conditions of such a mass of vapour from a purely chemical point of view. At certain temperatures combinations of some substances will become possible, heat will be developed, and various phenomena may be produced. Dr. Lohse[1] has already suggested that this kind of action might be the cause of the outburst of a new star.

Dr. Brester appears to unreservedly accept Mr. Lockyer's view, that many of the substances with which we are familiar in our laboratories are dissociated into their finer constituents at solar temperatures.

In accordance with the generally accepted notion, he also assumes the sun to be gaseous, and regards the photosphere as a shell of partially condensed matter. He rejects, however, the idea that the sun is in an almost constant state of agitation. Indeed, the unique point of his theory is that the sun is always in a state of perfect tranquillity, and that the so-called "eruptions" do not really indicate the actual displacement of matter, but simply the translation of the luminous condition. He boldly declares (p. 4) that "the solar eruptions do not exist," and looks to the known facts of chemistry to explain the multitudinous phenomena with which students of solar physics have to deal.

What Dr. Brester calls "New Astrochemical Principles" are stated as follows:—

> *Principle I.*—All incandescent celestial bodies are tranquil in themselves, and their quiet interiors are such that the molecules of different densities, arranged by gravitation in concentric spheres, never lose their stratification.
>
> *Principle II.*—The continued cooling of stars generally produces in their exterior layers an intermittent transformation of chemical energy in the form of heat, and thus produces periodical eruptions of heat.

Let us see how, with these premises, Dr. Brester treats some of the problems of solar physics.

The Formation of Spots.—According to the new theory, spots are openings in the photosphere produced by the heat developed in the chemical combination of dissociated molecules, part of the photosphere being evaporated when such an "eruption of heat" occurs. On this supposition the spot has the same temperature as the photosphere itself, the condition of things being somewhat similar to that of small pools of water in a mass of ice. Dr. Brester shows how this view gives an explanation of the proper motions and other phenomena of spots, but we must needs refer those interested to the book itself for full details.

The Stratification of the Sun's Atmosphere.—All solar physicists agree that in the solar atmosphere there is a stratification of some sort, but there are different views as to the exact nature of it. The old idea was that each vapour extended from the photosphere upwards, reaching to a height depending upon its density. This view had its birth in the observations showing that all the bright lines of the chromosphere appear to reach the photosphere, but Mr. Lockyer showed,[1] that as we have not to deal with a cross section in the observations, the same result would be obtained if the vapours were arranged in true shells. Mr. Lockyer follows up this important fact with the suggestion that the various layers are really concentric shells arranged according to their heat-resisting power, any particular substance finding its level where the temperature is just below that of dissociation for the vapour in question. Dr. Brester, however, goes back to the old view that the layers are arranged in the order of their specific gravities, but modifies it by supposing, with Mr. Lockyer, the vapours to lie in shells. Further, accepting the dissociation hypothesis, he regards some of these layers as finer constituents of what the chemists call elements.

Dr. Brester imagines that Mr. Lockyer's view demands that the most dissociated, and therefore the lightest molecules, should be found in the layers nearest to the photosphere, while the least dissociated, and therefore the heavier molecules, should appear in the outer layers. This, however, is not the case, according to our author; the lighter vapours, such as the hypothetical *helium* and hydrogen being furthest removed from the photosphere; while the heavier, such as iron, appear only in the lower levels. The whole subject has been very fully discussed by Mr. Lockyer in his "Chemistry of the Sun," and space does not here permit all the arguments to be restated. It may be mentioned, however, that, as Mr. Lockyer points out (p. 172), there is no evidence that the various metals are arranged according to densities; the case of magnesium and sodium is instanced, the heavier metal always showing the longer lines.

In a foot-note on p. 17 Dr. Brester states that the various elements need not always appear exactly in the order of their specific weights, "Car la hauteur où seront encore visibles les molecules d'une matière quelconque ne dépendra pas uniquement de leur poids mais de leur nombre aussi." It is by this bare statement that he attempts to explain the great height to which the H and K lines of calcium have been shown by recent photographs to extend, and presumably also such cases as that of magnesium and sodium, which has already been referred to. It is unnecessary to say more on this point, as Dr. Brester practically renounces this point of his theory

---

[1] *Berlin Akad. Monatsb.*, 1877, p. 826.

[1] "Chemistry of the Sun," p. 305.

The problem of the stratification of the sun's atmosphere does not, therefore, appear to have been advanced by his discussion of the various observations.

Dr. Brester's view of the solar surroundings leads him to suppose that the concentric layers which he postulates are ellipsoidal, so that the photosphere cuts different shells in different latitudes. The fact that there is an equatorial extension of some sort is abundantly demonstrated by eclipse photographs. In the application of this view to the explanation of some of the phenomena presented by the sun Dr. Brester displays considerable ingenuity, and we may refer to some of them, as they suggest points which may have to be taken into consideration in other theories.

The Solar Rotation.—It is a matter of common knowledge that the equatorial regions of the sun, as indicated by the spots, rotate more rapidly than the regions in higher latitudes. On Mr. Lockyer's hypothesis, which supposes sun-spots to be produced by the fall of condensed materials from the cooler regions of the atmosphere, this is explained by the fact that such atmosphere is highest at the equator, and the spot-forming matter thus having a greater forward velocity previous to its descent, will have a greater angular velocity on reaching the photosphere. Dr. Brester's view is a modification of this. Taking for granted that the solar layers are ellipsoidal, and that the photosphere is an independent partially condensed shell, he points out (p. 44) that when the matter of any particular layer condenses to form a part of the photosphere, the increase of density will cause it to descend towards lower layers, and as it will retain its initial velocity, the angular velocity in its new position will be increased. In this way he explains the law of solar rotation, but on account of the absence of knowledge of the densities of the vapours near the photosphere, the question cannot be treated mathematically. On Dr. Brester's view this law applies only to the photosphere itself, the ellipsoidal layers all having the same angular velocity.

This he further applies to the reconciliation of the spectroscopic determinations of the velocity which have been made by Dunér and Crew. Dunér's observations practically confirm the law derived from the observations of spots, while those of Prof. Crew show no change of velocity with change of latitude. Dr. Brester points out that most of the lines observed by Crew have been seen bright in the chromosphere, while those observed by Dunér have not been so recorded. Hence he concludes that the lines observed by Dunér are produced by the absorption of vapours actually lying in the interstices of the photosphere—and therefore indicating the same velocity—while those observed by Crew show only the uniform angular velocities of the ellipsoidal shells.

Changes in the Spectra of Sun-spots.—Dr. Brester's theory also gives an explanation of differences in the spectra of sun-spots at different parts of the spot-period. Observations have shown that at maximum the lines which are most widened in spot-spectra are chiefly lines of unknown substances, while at minimum they are chiefly lines of iron and other known substances. When it is remembered that there is a progression in latitude with the advance of the spot-period, Dr. Brester's view can readily be understood; the photosphere in each latitude will have a different composition, and hence change of latitude will be accompanied by change of spectrum. It is only fair to say that the exact nature of this change has not yet been fully investigated, and hence the explanation offered cannot strictly be put to the test. Broadly speaking, however, it is evident from what has already been said, that if Dr. Brester's view be correct, there must be a layer of unknown vapours cutting the photosphere about latitude 15° (the latitude of spots near maximum), and layers of the vapour of iron, or some of its constituents, cutting the photosphere about latitudes 5° and 30° (the latitudes of spots at minimum). Before the view can be properly tested, it is clear that we must have further knowledge as to whether the iron lines widened in spots of high latitude at the beginning of a sun-spot period are identical with those widened in spots near the equator towards the end of the period, and, so far as we know, information on this point is wanting.

The Periodicity of Solar Phenomena.—Dr. Brester first of all dismisses the suggestion of planetary disturbances as the phenomena usually seen are too irregular to be consistent with orbital motion; and other views are also found wanting. He then shows how the second of the astrochemical principles already referred to appears to him to give the necessary explanation. As in our notice of his first essay, we may say that the main idea is that during eleven years the integrated effects of the various chemical combinations which have taken place are such as to very nearly restore the conditions which had existed at the commencement of the period. Slight differences would be produced each time, so that after a long interval wide differences might be expected.

Many other problems are discussed, and Dr. Brester has satisfied himself that his theory is competent to explain them all. Want of space, however, will not permit further reference.

The volume will be a valuable one, if only for the fact that it brings together a great mass of work which has been done in connection with the sun—over 300 authors being quoted—and although we are not prepared to accept his theory in all its points, it is fair to say that some of his arguments are extremely suggestive, and may help in time to unravel some of the mysteries of our central luminary.

In subsequent communications Dr. Brester will extend his theory to the phenomena presented by variable stars, comets, and other celestial bodies. A. F.

ELEMENTARY BIOLOGY.

A Course of Practical Elementary Biology. By John Bidgood, B.Sc., F.L.S. (London: Longmans, Green, and Co., 1893.)

THIS book deals with certain of the types of animals and plants which are included in other elementary works on the same subject. The forms selected are yeast, protococcus, bacteria, mucor, penicillium, chara, fern, flowering plant, amœba, vorticella, paramœcium, hydra, mussel, crayfish, and frog. The author states that "the subjects dealt with cover most elementary biological courses, but apparently do not exactly fit any." The work has, therefore, at any rate, the merit of not having been written merely from the point of view of any particular examination syllabus. A certain amount of originality is also seen in the attempt to combine a more general treatment of the subject with practical directions.

General instructions with regard to the microscope, microtome, and reagents, are given in the introduction; these, however, do not indicate a very wide personal acquaintance with the ordinary laboratory requirements, and the methods of preparation, &c., are mainly copied from Lloyd Morgan's "Animal Biology" and Howes's "Atlas of Practical Elementary Biology." The student is referred to a number of well-known text-books for further information, but it is curious that no mention is made of certain excellent elementary works treating more especially of the types described.

The part dealing with plants, which occupies rather more than half the book, is on the whole more satisfactory and contains fewer mistakes than that relating to animals. Most of the woodcuts in the former are taken from well-known sources, and a number of original figures are given of *Aspidium* and of *Lamium album*, which latter is selected as a type of the Phanerogams; the author has evidently worked out the structure of these forms with some care. In the zoological part many of Lloyd Morgan's diagrams have been utilised, and figures are also taken from various other text-books, such as Milnes Marshall's "Frog," Wiedersheim's "Comparative Anatomy," and Quain's "Anatomy." Most of those from the last-named work, with the corresponding descriptions, naturally do not refer to the frog at all, but this fact is not stated. Some of the drawings of invertebrates made by the author are very fair, though they do not indicate much originality; one or two others, such as that of an undischarged nematocyst of hydra, on p. 221, are bad. The sources from which borrowed figures are taken is not mentioned in all cases, although the contrary is stated in the preface.

The author shows very little power of selecting his facts, or of drawing conclusions from them in such a way as to clearly illustrate the general principles of the subject. Many of the details, moreover, are incorrect, and errors of the most serious character occur. It will be sufficient to refer to a few of these in order to indicate the author's looseness of expression and want of acquaintance of parts of the subject with which he deals.

The remarks on the structure and functions of the nucleus, and on the pulsating vacuole in protococcus (pp. 46 and 47) are, to say the least, misleading. This organism may, it is said, "be looked upon as a closed bag with a double wall—the outer of cellulose, and the inner of protoplasm" (p. 50), and the movements of its cilia "probably" drive it through the water (p. 48). The investment of the "spermocarp" of chara is called a "pericarp," and the pro-embryo a "prothallium" (pp. 88 and 89). The description of karyokinesis (p. 108) does not show much knowledge of recent observations. On p. 90, line 10 from top, the word "sexual" has by an oversight been printed as "several." The oosphere is confused with the fertilized ovum on p. 133, although the term oosperm is correctly used on previous and subsequent pages. The description of the part played by the nucleus in the processes of reproduction and conjugation in vorticella on pp. 211 and 212 is somewhat incomprehensible. One gathers on pp. 220 and 221 that it is comparatively easy to distinguish the nerve cells in hydra in preparations simply traced up in water and stained with methyl-blue, and in optical sections of the entire animal prepared with osmic acid. We may mention that it has recently been shown by Albert Lang that the bud in hydra is *not* "a product of both ectoderm and endoderm" as stated on p. 223. The Metazoa are said to be *all* "characterized by . . . the possession of a digestive cavity (*enteron*)" (p. 224). On p. 234 we read that the "kidneys (nephridia)" of the mussel are "sacculated organs whose walls carry a mass of tubules," and one gathers that the small irregular opening leading from the kidneys into the "ureter" is quite easy to recognise. Fig. 194A, representing the brain of the frog, is taken from the old figure by Ecker, in which the "olfactory lobes" are separated by a cleft, and the primary fore-brain is said to be the same thing as the thalamencephalon (p. 333). We do not see the object of introducing a description of the complicated human auditory apparatus in the chapter on the frog. The account of the processes of maturation, fertilization, and segmentation of the ovum of the frog is extremely incomplete and inaccurate, and one might even infer from one sentence on p. 331 that the nucleus was quiescent during the division of the egg! We are told that the ectodermic invaginations which give rise to the "nares" become "continuous with the mesenteron" (p. 335). The description of the development of the lungs (p. 334), together with the figure copied from Wiedersheim, refer to the mammal, and not to the frog. In the account of the development of the body-cavity (p. 335), it is said that the latter, "extended upwards through the lateral mesoblastic plates, nearly meets in the middle line beneath the notochord, and so pinches the alimentary canal with its glands into the body cavity"; and on page 333 it is stated that the notochord "pierces the mesoblast and divides it into right and left halves." The numbering of the *five* aortic arches given in Fig. 225, and that of the *three* mentioned in the text is incorrect (p. 336). We learn that metamorphosis begins soon after the development of the gills (p. 336). The account of the development of the urinogenital ducts on p. 338 is quite incorrect as applied to the frog. In Chapter XVIII. one gathers that the processes of digestion in all the Cœlomata are quite similar to those which occur in the higher forms, which are then briefly described.

Even if we accept the author's dictum that "he will know a good deal of botany who knows Chara and Lamium thoroughly," and give him full credit for having worked up some parts of the subject practically, we must remind him that a wider knowledge than this implies is advisable before attempting to write a book on general biology. After reading the preface and introduction, one is led to expect that the high ideal set up by the author as regards actual personal observation would at any rate have led him to examine carefully and accurately all the types described; it is very disappointing to find that this has not been the case. In conclusion we venture to repeat Darwin's advice as quoted on p. 200 of this book: "Give full play to your imagination, but rigidly check it by testing each notion experimentally."

VAN'T HOFF'S "STEREOCHEMISTRY."

Stéréochimie. Nouvelle Edition de "Dix Années dans l'Histoire d'une Théorie." Par J.-H. van't Hoff. Rédigée par W. Meyerhoffer. (Paris: Georges Carré, 1892.)

THE second edition of this work was very fully reviewed in these columns in 1887 (vol. xxxvii. p. 121), and we will therefore content ourselves with noticing briefly the new matter contained in the present edition.

We must, however, premise that the stereochemistry of the carbon compounds is based on the assumption that the four monad atoms or groups satisfying the four affinities of a carbon atom are situated at the solid angles of a tetrahedron, the centre of which is occupied by the carbon atom itself, and on the allied conception of the "asymmetric" carbon atom—"asymmetry" arising when the four attached atoms or groups are dissimilar, in which case two enantiomorphic arrangements are possible for any given set of four such atoms or groups (see the notice already referred to). In the first French edition, which bore the title "La Chimie dans l'Espace," the author discussed the greatly increased possibilities of isomerism to which this new theory led. Since then chemists have used the theory as a guide in the search for cases of isomerism, and numerous new isomeric compounds have been discovered, the existence of which could not have been predicted as long as the old constitutional formulæ written in one plane were employed. The history of this branch of organic chemistry has, during the past seven or eight years, been one continuous triumph for the theory. One of the most striking proofs of the value of these stereochemical views is to be found in Emil Fischer's well-known researches on the sugar group. In the group of the glucoses of the aldehyde-alcohol type, for example, the presence of four asymmetric carbon atoms has to be assumed, and the theory predicts the existence of no fewer than sixteen isomerides with a normal carbon chain, as compared with the one form admissible under the older view. Several of the predicted forms have been prepared, and the relative distribution of the positive and negative asymmetric carbon atoms within the molecule has been determined by E. Fischer. This and other work confirmatory of the theory, is described and discussed in the present volume.

The theory of the asymmetric carbon atom owes its origin to the difficulty of otherwise explaining the optical rotatory power of various organic compounds. Quite recently, P. A. Guye has suggested that the numerical value of this optical rotatory power is dependent upon the relative masses of the substituting atoms or groups attached to the asymmetric carbon atom, and that if two of the four different substituting radicles are of equal mass the rotatory power will cease. He was unable to verify this view in all strictness, since, in the cases of this kind which he studied, such as that of methyl-ethyl-aldehyde $(C_2H_5)(CH_3)CH(COH)$, in which $C_2H_5 = COH = 29$, there was optical activity. The probable explanation is, that, as suggested by Guye, not only the masses of the groups, but also the interatomic distances, of which the atomic volume is a measure, come into play here. However, by varying the weight of a given group attached to an asymmetric carbon atom—thus, by substituting successively different homologous radicles—it was found possible to produce a concomitant variation in the rotatory power of the compound, to make it increase or decrease at will, and even to change its sign. This variation is shown in ascending the series of the esters of tartaric acid and its di-acetyl and di-benzoyl derivatives. But whereas the weight of the alkyl-group in the esters determines the amount of the rotatory power, no such influence can be perceived in the case of the metallic salts of tartaric acid, all of which display in solution the same rotatory power, irrespective of the atomic weight of the metal. The clue to this anomaly is furnished by the electrolytic dissociation theory of Arrhenius, according to which the dissolved salts are present in the form of their dissociated ions, so that, in the case of the dissolved metallic tartrates, it is the ion $CO_2(CH.OH)_2CO_2$ which is alone responsible for the rotation. Arrhenius's theory thus receives striking confirmation from an unexpected quarter.

The subject of compounds containing closed chains is fully discussed in the present edition, and the "cis" and "trans" isomerism discovered by von Baeyer is described.

The relative position of the substituting groups in the stereo-isomerides is also discussed.

The concluding chapter deals with the stereochemistry of nitrogen—a question which had not emerged when the previous edition was published. Some of the information given under this heading is rather meagre; but doubtless the omissions are intentional and they are largely compensated for by a very complete bibliography of the subject.

The work is in every sense authoritative, and we cordially recommend it to all interested in the most recent developments of organic chemistry.

F. R. J.

OUR BOOK SHELF.

Die Fossile Flora der Höttinger Breccie. By R. von Wettstein. With 7 plates. (Vienna: Imperial Printing Office, 1892.)

THE Höttinger Breccia is a formation about 50 feet thick in the neighbourhood of Innsbrück, and situated about 1200 metres above sea-level. The upper part consists of about 35 feet of coarse conglomerate, with fossils chiefly confined to a bed some 3 feet thick, while the remainder is occupied by alternating beds a foot or two in thickness of white or reddish sandstones and breccias, which are for the most part very fossiliferous. It has been well known to collectors of fossil plants for upwards of thirty years, and though at first regarded as of tertiary age, is now uniformly recognised as quarternary, possibly inter-glacial, or more probably post-glacial. The lower part is characterised by the occurrence of many herbaceous plants, such as the violet, strawberry, coltsfoot, Prunella, &c., which are replaced above to some extent by *Cornus sanguinea*, *Rhamnus Frangula*, an alder, willow, &c., indicating, perhaps, a change in the forest growth without necessarily implying any considerable interval of time. The flora is almost wholly of existing species, and in the main does not differ essentially from that which might be found in a similar situation at the present day; but six of the species no longer flourish at such an altitude, and a few others, like the box, are absent in Northern Tyrol, while there are also indications in the relative sizes of the leaves of others that the climate was milder. Perhaps the Alps were less elevated and the sea nearer at the time, but interest is given to the problem by the undoubted presence of *Rhododendron ponticum*, which at present only flourishes in a much warmer climate far to the east, but, from its discovery in other localities, was evidently thoroughly indigenous in the Alps. The author regards the flora as a relic of the "steppe-flora" which then spread over the greater part of Europe, and of which numerous traces still exist, especially in Switzerland and Lower Austria, where plants of Oriental facies, such as the yew, box, holly, Ephedra, Sumach, hornbeam, feather-grass, maidenhair, &c., are its lingering remains.

The work is carefully prepared, doubtful determinations, except in the case of the Arbutus and a new buckthorn allied to *Rhamnus latifolia* of the Canaries, are eschewed, and the photographic illustrations, pencilled over by the artist, are extremely satisfactory. J. S. G.

Observational Astronomy. By Arthur Mee, F.R.A.S. (Cardiff: Daniel Owen and Co., 1893.)

THIS small book should serve the purpose for which it is issued; the object being to provide the beginner with an inexpensive treatise to enable him to become familiar with and interested in the practice of observational astronomy. For this reason the author limits himself to the purely descriptive side of astronomy, dealing with the sun, planets, comets, and meteors, giving numerous references where necessary. Short chapters are given on eclipses, transits, occultations, and "the sidereal firmament," the latter treating of double and coloured stars, &c. The chapter on the telescope contains many practical hints, besides numerous woodcuts, while that devoted to the moon is very pleasant reading, and gives a good account of the more general features. The illustrations, as will be gathered from the above, are very numerous, many of them being from the pen of the author himself. With respect to these, we must add that the one given on p. 72 of the Orion nebula does not remind us of the most beautiful object in the heavens, while on p. 66 Donati's comet is depicted minus the two long streamers which made this object so striking. The book concludes with a short obituary of the Rev. T. W. Webb and an appendix containing brief contributions from Denning on comets and meteors, Gore on variable and temporary stars, Seabroke on double star measurement, and a few others.

W. J. L.

Mechanics and Hydrostatics for Beginners. By S. L. Loney, M.A. (Cambridge University Press, 1893.)

THIS is the latest addition to the series of elementary text-books recently launched by Mr. Loney. The same high standard of excellence is maintained, and the author must again be congratulated on his efforts to place in the hands of a beginner a book which will give him correct ideas of the laws and principles which are included in a study of mechanics.

It consists of three parts, statics, dynamics, and hydrostatics, each part containing the usual chapters. If the reader should fail to understand the chapter on the laws of motion, he must attribute it either to his want of ability or the nature of the subject, for we fail to see how the author could improve his remarks on this part of the subject. We are glad to observe that the words "rate of change" find their way into the statement of the second law, for its definiteness is increased thereby. More than the usual care appears to have been devoted to the selection of suitable examples; some of them are exceptionally good, and thus add to the usefulness of the book. Occasionally the trigonometrical ratios are used, but their definitions will be found in the appendix; we are afraid, however, that the suggestion that their values for certain angles should be committed to memory is not a wise one. G. A. B.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Glacier Theory of Alpine Lakes.

THE letter of the Duke of Argyll against the theory of the formation of alpine lakes by glacial action shows such an amount of misconception of the theory itself, and so completely ignores the great weight of evidence in its favour, that a few words on the other side seem desirable.

The Duke says that glaciers "do not dig out," do not "act like a ploughshare," but, when moving down a slight incline do "scoop," as well as rub down and abrade. No observer of glaciers has ever stated, so far as I know, that they do "dig out," and it is equally erroneous to say that they "scoop," for that implies that it is the end of the glacier that acts. But the end is its weakest point, where it is melting above and below, and where consequently it can do practically nothing. The whole action of a glacier is a grinding action, and its grinding power is greatest where it is thickest, and where, consequently, it presses on the rocks with the greatest weight. The result of this grinding is seen in the muddy stream issuing from all existing glaciers; while the well-known "till" is the product of the rock grinding mill of ancient glaciers and ice-sheets.

Notwithstanding the Duke's disbelief in ice-sheets I venture to think that their former existence has been demonstrated both in Scotland and Ireland; but leaving this point, I wish to make a few remarks on the extreme inadequacy of the earth-movement theory to account for the facts. In the first place it is certain that no alpine lake can possibly have a long life, geologically speaking. In the course of a few thousands of years, certainly in less than a hundred thousand, all alpine lakes would be filled up by the sediment brought into them. It follows that all the existing lakes must have been formed about the same period, and that, geologically, a very recent one, and corresponding approximately with that of the well-known glacial epoch. But if these lakes were all formed by earth movements, either just before the glacial epoch came on, or during its continuance, or afterwards we have to explain the remarkable fact that such movements only occurred within the limits of glaciation, never beyond those limits. In Wales, Cumberland, and Scotland, in the Alps, in Scandinavia, in Finland, in the northern United States and Canada, in Mongolia and Thibet, in Tasmania and New Zealand, we have thousands of rock-basin lakes, amid palpable signs of glaciation. But the moment we pass beyond the glaciated districts, mountain lakes abruptly cease. There are hardly any in Spain, none in the Great Atlas, none in Sardinia or southern Italy, except in the volcanic areas and away from the mountains, none in any of the West Indian islands with their fine mountain-ranges, none in the peninsula of India or in Brazil. And there is exactly the same distribution of fiords. We have them in Norway, in West Scotland, in Alaska, in South-West America, and in New Zealand, all characterised by deeper water within than at their outlets, and all in glaciated countries, but nowhere else in the world.

Now it is simply impossible to believe that at a very recent period there should have been earth-movements of such a character as to produce lakes, but always in glaciated districts and never beyond them, unless the movements were a result of the glaciation. This has not, I believe, been yet suggested; but, in view of the modern theory that any considerable loading of the surface produces subsidence, it is at least a possible explanation. But there are some important facts that seem more in favour of the grinding out of the lake-basins by the enormous weight of ice accumulated over their sites during the height of the ice-age. Looking at a geological map of the Alps it will be seen that most of the lakes are more or less bordered by tertiary or secondary rocks. Lakes Annecy and Bourget are in miocene and eocene; the lake of Geneva on the north side is miocene or jurassic; the lake of Neuchatel, miocene; lakes Thun and Brienz, eocene or jurassic; lake Lucerne, eocene and miocene; lakes Zug and Zurich in miocene; lake Constance miocene; lake Maggiore is mostly in gneiss, but it is very suggestive that it is here comparatively shallow, but becomes suddenly deeper and reaches its maximum depth in its lower portion where it is bordered on the east by the jurassic beds; lake Como also has its greatest depth in triassic rocks, the upper portion, where gneiss prevails, deepening gradually southward as in a submerged valley. Equally suggestive is the fact that in the eastern Alps of Tyrol and Carinthia, where gneiss, porphyry, and the older stratified rocks prevail, and where glaciers are not now so extensive, there are hardly any lakes, except on the northern borders, where a considerable number occur in eocene, cretaceous, jurassic, or triassic formations.

These various facts as to the distribution of alpine lakes—their almost total absence in all parts of the world outside of glaciated districts, and within glaciated districts their prevalence in the newer and more easily denuded rocks—are what have to be explained by the advocates of the theory of earth-movements, and this, so far as I am aware, they have never attempted to do. Equally important, and equally difficult to explain on the earth-movement theory, is the fact that alpine lakes are almost always situated just at those spots where, by means of converging valleys, the glaciers would become heaped up and attain their maximum thickness, or where there is good evidence that they have been very thick; and it is the grinding power of this enormous weight of ice, acting differentially as regards the softer and harder rocks, that has worn out hollows in pre-existing valleys now occupied by lakes. In almost every case, too, it will be seen that there is a constriction or narrowing of the valley towards or beyond the lower end of the lake, which, by preventing the free escape of the ice, has increased its thickness and grinding power.

In the presence of such important series of facts as those here referred to, mere opinions, or even small and detailed cases of difficulty, can have no weight; but there is yet another consideration, which most geologists will admit is antagonistic to the earth-movement theory. The whole tendency of geological observation is in favour of the usually very slow rate of earth-movements, while it is equally in favour of the comparatively rapid action of denudation by running water. But in order that earth-movement could form a lake, it would be necessary that the rate of elevation or depression should be so great that the river could not keep pace with it by cutting down its channel; and, considering that all the rivers in question are rapid mountain streams carrying great quantities of sediment, this will be admitted to be a very improbable supposition. But when we add to this the still greater improbability that such rapid earth movements have occurred in scores and hundreds of cases, all at about the same time, geologically speaking, and all just in those spots where it can be shown that during the glacial period ice must have accumulated, and where the rocks were of such a character as to admit of being ground away; and yet further, that no similar earth movements producing similar results have recently occurred in any part of the globe beyond the limits of glaciation, the whole assumption becomes so hugely improbable as to render the theory of lake-formation by ice-grinding easy in comparison.

Sir Charles Lyell considered that the gravest objection to the glacial-erosion theory was the entire absence of lakes where they ought apparently to exist; and he instanced the valley of Aosta and the Dora Baltea, the glacier of which produced the enormous moraines of Ivrea. The valley of the Rhone above Martigny may be adduced as another example of the absence of lakes where they might be expected. But this kind of difficulty will apply to many other valleys, and can only be answered by general considerations. In both these cases the valleys are comparatively broad and open, and have a rather rapid descent. It is probable, therefore, that the ancient glacier in both was of a nearly uniform thickness, so that its wearing action on the floor of the valley would be tolerably uniform. To produce a lake we require essentially a differential action. There must be much more rapid degradation in one part than in another, due either to greater ice-accumulation or to softer rocks in one part than in another. In both the valleys referred to there is much uniformity in the rock-formations throughout, and even if some lakes or chains of lakes had been formed, the enormous amount of debris still brought down may well have filled up and altogether obliterated them. The absence of lakes in certain valleys cannot be considered an argument of any value until it is ascertained by borings that none have been formed and filled up again. It must also be shown that the whole conditions are such as to produce that amount of differential grinding down, without which no lake can be expected to have been formed.

It certainly seems to me that all the facts, all the probabilities, all the converging lines of evidence, are in favour of the glacial theory, to which the only serious objection is the assumption that glaciers cannot move uphill. But that they can do so, and have done so, is now admitted by most students of glacier-motion. Mr. Jamieson, and other Scotch geologists, have proved that glaciers, over 2000 feet thick, have travelled up lateral valleys, and up the slopes of many hills and mountains; and when we consider that the Rhone glacier was 5000 feet thick just above the lake of Geneva, and more than 2000 feet thick where it abutted against the Jura, we can have no difficulty in admitting that it might have travelled up the very gentle slope of the lake bottom, which appears to be less than 100 feet in a mile in its steepest parts. ALFRED R. WALLACE.

Waves as a Motive Power.

HAVING frequently observed the swimming motions of the fishes in our Aquarium—and occasionally of porpoises in the open sea—I have tried to make use for propelling boats of the same principle of locomotion, as exemplified particularly in the tail-fin.

I fixed a fin (blade) of elastic material like a helm to the end of a canoe; moving that fin laterally to and fro, the same went forwards. I have since learned that this "motor" was used already twenty-five to thirty years ago by Ciotti, a Sicilian; it is of course only an exact version of the method of sculling with one oar, familiar to all boatmen. Whilst trying my canoe and models of boats I soon became convinced that a boat ought to move forward if elastic fins are fixed to it, directed backwards, in such a manner that their flat sides are pressed against the surrounding water, when the boat rolls and pitches. The elastic fins, whilst overcoming the resistance of the water, curve like the fins of a fish, driving the water backwards and consequently pushing the boat forwards.

The canoe was provided with two horizontal fins at the stern and two vertical ones at the keel, total surface 0·2 square metres; speed against rather sharp wind and waves estimated at 25 metres per minute. I was unable to take exact measurements, as the canoe was accidentally sunk before the experiment was complete.

I then provided another boat, three metres long, at each of the two pointed ends with a horizontal fin (later on two), and at the keel with two vertical fins; these were all made of steel sheet, 1 – 0·8 mm. thick, subsequently replaced with aluminium bronze. The boat covered, against a gentle sea and wind, the distance of 900 metres in 25 minutes. Putting the fins obliquely the boat turned towards the right or left; directing one group of the fins forward, and another of equal surface backward, their action was paralysed, and in similar manner it was easy to make the boat turn round on the spot or to move backward.

The changing of the surface of the fins (0·3 to 0·6 square metres) caused very little difference in the speed produced. The same movements of the boat take place if the rocking is caused artificially.

I undertook a series of trials, in which I wish to acknowledge with thanks the kind assistance of Mr. Nelson Foley. The first result was that the *rolling* yields so little power, (very little energy being sufficient to prevent rolling,) that the vertical fins as a source of power may be nearly neglected in the calculations.

As to *pitching*, the power resulting from the action of the waves against gravity is proportioned to (weight of boat with crew) × (number of undulations) × (height of waves). But only a small portion of the energy developed in moving the boat up and down acts upon the fins (surface of boat in water-line three square metres, surface of fins 0·3 to 0·6 square metres), and of this remaining available force a considerable portion is lost by the low efficiency of the fins. Supposing, for the sake of argument, the efficiency to be 25 per cent., the propelling capacity in a moderate sea works out to the fraction of a man's power.

Considering these circumstances it seems doubtful, even with considerable rocking and using boats of more advantageous forms than mine, if it will be possible to have a much higher speed than 2000 metres per hour. It appears also that the available force will be hardly sufficient to struggle successfully against strong winds and currents.

I do not therefore prognosticate too confidently any practical value to the motor, but should be very glad if some of your readers would inform me as to any similar experiments which may already have been made. H. LINDEN.

Zoological Station, Naples, February 19.

Blind Animals in Caves.

As a reader of Mr. Herbert Spencer's writings and a disciple of his, I shall be very glad to lift Prof. Lankester's glove. In the first place I would point out that the process he describes is not natural selection in the ordinary sense; natural selection is the death of the unfit and the survival of the fittest. In the suggested process neither the animals with perfect eyes, nor those with imperfect, are destroyed in the struggle for existence; they are simply segregated. But this is of minor importance. The question is whether there is any foundation for the hypothesis suggested.

Prof. Lankester supposes that the individuals born with defective eyes have remained in the dark places, while those with perfect eyes have followed the glimmer of light and escaped. But he has overlooked the fact that blind cave-animals are *born or hatched at the present day with well-developed eyes*. It is clear, therefore, as in every other case to which the law of recapitulation applies, that the variations to which the evolution is due occurred at a comparatively late period in the life of the individual. Why did not all the individuals escape when they were young, and could still see without spectacles? When the imperfection of the eyes did occur, what ground is there for assuming that it was a congenital variation? It seems to me perfectly certain that it was a deterioration of the eyes caused by the fact that the individual had lived in the dark all its life. In short, I hold that the law of recapitulation in development, the law of metamorphosis, or biogenetic law, as Haeckel called it, is itself a sufficient proof of the inheritance of acquired characters. This argument has never been met or even considered by any of those who talk of congenital fortuitous variations without defining them.

The evidence for the statement I have made is, I confess, not quite complete, but it is sufficient for my present purpose. In Semper's "Animal Life," p. 80, there is an account of *Pinnotheres Holothuriæ*, based on the author's direct observations. This species lives in the respiratory trees of Holothurians, and in the adult the eyes are degenerate and invisible on the exterior of the animal. The young is hatched as a zoæa with perfect typical eyes; even when it enters the host it retains its eyes, but afterwards the eyes degenerate and become covered over by the carapace. In the common mole, to take an instance among mammals, the optic nerves are degenerate in the adult, so that there is no connection between eye and brain; but in the embryo both eyes are connected with the brain by well-developed optic nerves. I am not at present acquainted with any observations on the young of Proteus, or the blind fish Amblyopsis, or the blind Crayfish of the mammoth cave, but I am quite confident that the young in all these cases have relatively well-developed eyes. At any rate Prof. Lankester to support his theory must prove that they are blind from the beginning; for if they are not then it is clear that the variations which we have to consider took place during the life of the individual living in the dark, and consequently the support of Prof. Lankester's suggestion vanishes. Prof. Lankester again writes of the deep sea as though it were as destitute of light as the mammoth cave, or the subterranean home of the Proteus, but this is notoriously not the case. With regard to fishes, Dr. Günther says that below the depth of 200 fathoms small-eyed fishes as well as large-eyed occur, the former having their want of vision compensated for by tentacular organs of touch, whilst the latter have no such accessory organs, and evidently see only by the aid of phosphorescence; in the greatest depths blind fishes occur with rudimentary eyes, and without special organs of touch. Dr. Günther mentions fifty-one species of fishes living at depths beyond 1000 fathoms, and among these only three *Aphyonus gelatinosus*, *Typhlonus nasus*, and *Ipnops Murrayi* are blind. It is, I think, sufficiently evident that the biology of the deep sea is quite different from that of subterranean caves or habitats. J. T. CUNNINGHAM.

Plymouth, February 27.

BESIDES panmixia and emigration of the more perfect-eyed individuals, as explained by Prof. E. Ray Lankester, allow me to suggest another cause for the dwindling of the eyes in cave-dwelling animals.

Prof. Weismann says that the degeneration "can hardly be of direct advantage to the animals, for they could live quite as well in the dark with well-developed eyes." I submit, however, that in a place permanently dark the eye is not merely useless, but, as a delicate and vulnerable part, it becomes a positive source of danger to the animal. No longer helping the creature to avoid obstacles or danger, it is, in proportion to its size, exposed to injury, destructive inflammation, and the attacks of parasites in a manner which must not seldom lead to the death of the individual. As other senses become more acute, and the eye recedes, this danger diminishes, and when the eye has become a mere rudiment, "hidden under the skin," its presence ceases to be a disadvantage, and so degeneration does not proceed to complete suppression.

It is a wonder that Mr. H. Spencer should have overlooked Prof. Lankester's explanation, for the English editor of Prof. Weismann's fifth essay has not failed to call attention to it.

Mirfield, February 27. A. ANDERSON.

[Darwin has himself drawn attention, in regard to burrowing animals, to the conditions pointed out in the above ("Origin of Species," 6th edition, p. 110).—ED.]

Foraminifer or Sponge?

I AM glad to find that Mr. Pearcey agrees with me in regarding *Neusina Agassizi*, Goës, as identical with *Stannophyllum zonarium*, Hæckel. But with respect to its systematic position I do not as yet see sufficient reason to differ from Prof. Hæckel in regarding it as a sponge, although I have never observed flagellated chambers and cells any more than he. The large masses of foreign bodies always present in this organism offer very serious difficulties in sectionising it, and as long as we are not absolutely certain about its cellular structure we are justified in thinking with Hæckel that general appearance and the presence of oscula, pores, subdermal cavities, horny skeleton, &c., are sufficient to characterise the form as a sponge.

Mr. Pearcey mentions six genera of Foraminifera which he thinks approach closely to *Stannophyllum*. I am sorry I cannot see much similarity. The chitinous lining in the tube-like body of some Foraminifera certainly bears not the slightest resemblance to the distinct fibrous stroma of *Stannophyllum*, which reminds me much more of the filaments of the true horny sponge *Hircinia*. If anything tells in favour of Mr. Pearcey's view, it is the concentric lines of *Stannophyllum*, which recall the foraminiferal rather than the sponge type of growth.

The final decision of this question can of course only be expected from an examination of the cell-structure.

University College, Liverpool, R. HANITSCH.

A Magnetic Screen.

DURING the last vacation St. John's College, Oxford, has been lit with the electric light, and a transformer of the dynamomotor type, weighing over seven tons, has been placed within about sixty feet of the electrical testing room of the Millard Laboratory, which is furnished with several reflecting galvanometers. I greatly feared that the instruments would suffer much from the magnetic field of the large transformer. When it was found that no other space could be given up for the machine, I devised a method of construction which the Oxford Electric Lighting Company very kindly carried out for me when building their dynamo house. My method is to construct a wall of scrap iron round the three sides of the dynamo nearest to our laboratory. The iron wall is about eight inches thick, and is made by building two brick walls parallel to one another, and filling the interspace with scrap-iron; a delicate magnetometer used for testing the field at unprotected and protected points equidistant from the magnets, when the machine is in action and not so, shows that the iron wall is an effective barrier to the magnetic influence. I venture to make known this method of shielding off a magnetic field, because in these days of electrical invasion it may be of use in protecting physical instruments from being seriously disturbed, and rendered useless for any but the roughest determinations. FREDERICK J. SMITH.

Trinity College, February 28.

ON ELECTRIC SPARK PHOTOGRAPHS; OR, PHOTOGRAPHY OF FLYING BULLETS, &c., BY THE LIGHT OF THE ELECTRIC SPARK.[1]

II.

GOING back now to the photographs, the next one was taken with the view of illustrating the effect on the inclination of the waves of the velocity of the bullet. In this case the bullet was aluminium ; it was only one-seventh the weight of the regulation bullet. In consequence of its lightness it travelled about half as fast again as the ordinary bullet (not $\sqrt{7}$ times as fast as it would have done if the pressure of the powder-gases had been the same in the two cases), and in consequence of the higher speed the inclination of the waves is still greater than in the previous case. Further, in this case the bullet was made to pierce a piece of card shortly before it was photographed. The little pieces that were cut out were driven forward at a high speed, but, being lighter than the bullet, they soon lost a large part of their velocity ; they had in consequence lagged behind when they were photographed, but though travelling more slowly (they were still going at more than 1100 feet a second) they yet made each its own air wave, which became less and less inclined as the bits lagged more and more behind ; each, moreover, produced its own trail of vortices like that following the bullet. The well-known fact that moving things tend to take the position of greatest resistance, to avoid the effect of which the bullet has to be made to spin, is also illustrated in the photograph. The little pieces that are large enough to be clearly seen are moving broadside on, and not edgeways, as might be expected.

In order to illustrate the other fact that the angle of the waves also depends on the velocity of sound in the gas, I filled the box with a mixture of carbonic acid gas, and the vapour of ether, a mixture which is very dense, and through which sound in consequence travels only about half as fast as it does in air, and which will not explode or even catch fire when an electric spark is made within it, or directly act injuriously upon the photographic plate. The increased inclination of the waves is very evident in Fig. 10.

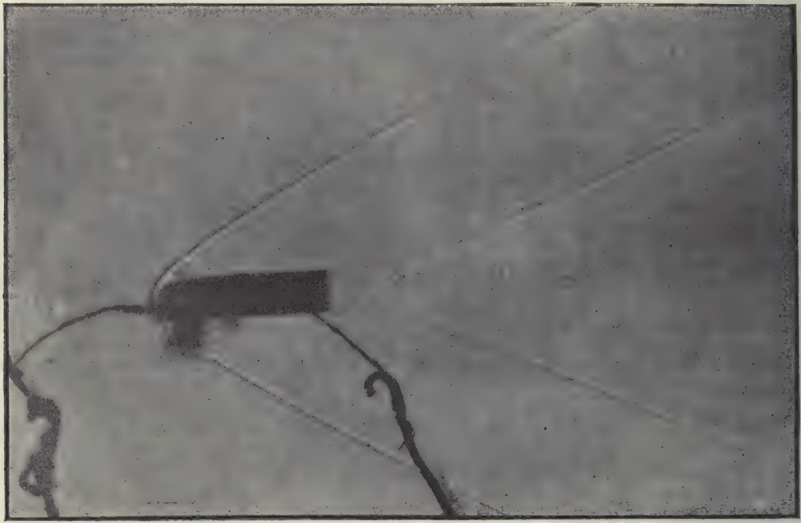

Fig. 10.

These waves, revealed by photography, have a very important effect on the flight of projectiles. Just as in the case of waves produced by the motion of a ship, which, as is well known, become enormously more energetic as the velocity increases, and which at high velocities produce as a matter of fact an effect of resistance to the motion of the ship of far greater importance than the skin friction, so in the case of the air waves produced by bullets ; in its flight the resistance which the bullet meets with increases very rapidly when the velocity is raised beyond the point at which these waves begin to be formed. This being the case, I have thought it might be interesting to see whether the analogy between the behaviour of the two classes of waves might be even nearer than has already appeared, and on turning to the beautiful researches of Mr. Scott Russell, published in the Report of the British Association for the year 1844, in which he gives a very full report on water waves and their properties, I found that he had made experiments and had given a diagram showing what happens when a solitary wave meets a vertical wall. The wave, as would be expected, is, under ordinary conditions, reflected perfectly, making an angle of reflection equal to the angle of incidence, and the reflected and incident waves are alike in all respects. This continues to be the case as the angle gets more and more nearly equal to a right angle, *i.e.* until the wave front, nearly perpendicular to the wall, runs along nearly parallel to it. It then at last ceases to be reflected at all. The part of the wave near the wall instead gathers strength, it gets higher, it therefore travels faster, and so causes the wave near the wall to run ahead of its proper position, producing a bend in the wave front, and this goes on until at last the wave near the wall becomes a breaker.

In order to see if anything similar happens in the case of air waves, I arranged the three reflecting surfaces of sheet copper seen in Fig. 11, and photographed a magazine rifle bullet when it had got to the position seen. Below the bullet two waves strike the reflector at a low angle, and they are perfectly reflected, the dark and the light lines changing places as they obviously ought to do. The left side of the V-shaped reflector was met at a nearly grazing incidence; there there is no reflection, but, as is clear on the photograph, the wave near the reflector is of greater intensity, it has bent itself ahead of its proper position as the water wave was found to do, but it cannot form a breaker, as there is no such thing in an air wave. The same photograph shows two other phenomena which are of interest. The stern wave has a piece cut out of it by the lower reflector, and bent up at the same angle. Now if a wave was a mere advancing thing the end of the bent-up piece would leave off suddenly, and the break in the direct wave would do the same. But according to the view of wave propagation put forward by Huygens, the wave at any epoque is the resultant of all the disturbances which may be considered to have started from all points of the wave front at any preceding epoque. The reflector, where it has cut this wave, may be considered as a series of points of disturbance arranged continuously in a line, each, however, coming into operation just after the neighbour on one side and just before the neighbour on the other. The reflected wave is the envelope of a series of spheres beginning with a point at the place where the wave and the reflector cut, growing up to a finite sphere about the end of the reflector as a centre; beyond this there are no more centres of disturbance, the envelope of all the spheres projected upon the plate, that is, the photograph of the reflected wave, is not therefore a straight line leaving off abruptly, but it curls round, as is very clearly shown, dying gradually away to nothing. The same is the case, but it is less marked, at the end of the direct wave near the part that has been cut out.

---

[1] Lecture delivered at the Edinburgh meeting of the British Association by C. V. Boys, F.R.S. Continued from page 421.

The other point to which I would refer is the dark line between the nose of the bullet and the wire placed to receive it. This is the feeble spark due to the discharge of the small condenser which clearly must have been on the point of going off of its own accord. The feeble spark precedes—or is to all intents and purposes simultaneous with, it cannot follow—the main spark which makes the photograph. The feeble spark heated the air, and the light from the main spark coming through this line of heated air was dispersed, leaving a clear black shadow on the plate. One spark casts a shadow of the other. Now it is evident that if the spark at the nose of the bullet had followed instead of having preceded the main spark by even so much as a three-hundred-millionth of a second, the time that light took to travel from one to the other, it would not have been able to cast a shadow. We have the means of telling, therefore, which of two sparks actually took place first, or perhaps the order of several, even though the difference of time is so minute. Perhaps this method might be of some use in researches

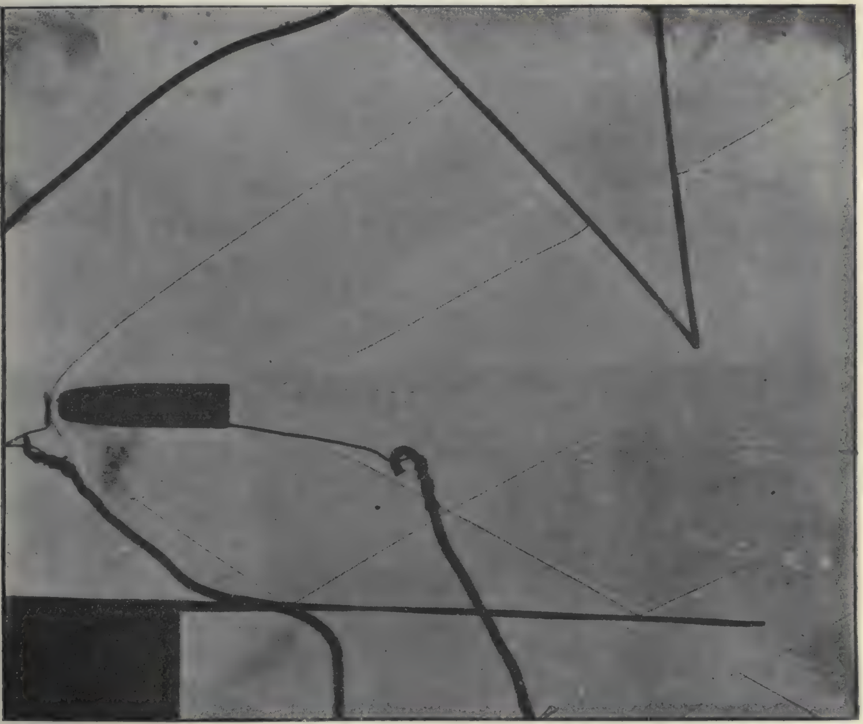

Fig. 11.

now attracting so much interest in connection with the propagation of electrical waves.

On returning to the non-reflection of the air wave in the upper part of the figure we have here, I imagine, optical evidence of what goes on in a whispering gallery. The sound is probably not reflected at all, but runs round almost on the surface of the wall from one part to another.

We are now in a position to see how the reflection or non-reflection of air waves produced by a passing bullet, when they meet with some solid body, may produce a practical result which might be of importance in some cases. Suppose a bullet to be passing near and parallel to a wall. Then if the velocity of the bullet and its distance from the wall are such that the head wave meets the wall at an angle at which it can be reflected, especially, as in the case of Fig. 11, if the reflected ray can only return into the path of the bullet after it has gone, then no influence whatever can be exerted upon the bullet by its proximity to the wall. If, however, the head wave would, if undisturbed, meet the wall at such an angle that it could not be reflected, as for instance, in Fig. 12, when the head wave can be reflected by neither of the walls between which the bullet is passing, obviously the wave will become stronger and the resistance which it offers will, I imagine, become greater, and if in this case the upper plate be removed this extra resistance will be one-sided and must tend to deflect the bullet. This is quite distinct from the well-known effect of a bayonet upon the path of a bullet; when a bayonet is fixed the rush of powder gases between the bullet and the bayonet is quite sufficient to account for the deflection which every practised marksman allows for.

I have devised a method by which a problem of some difficulty, about which authorities are, I believe, by no means in accord, may be solved with a fair degree of certainty. The problem is this, to find what proportion of the velocity of a bullet is given to it after it has left the barrel, or, what comes to the same thing, to find the position in front of the barrel at which the speed is a maximum. The cause of this is evident. When the bullet has left the muzzle the imprisoned powder gases, under enormous pressure, rush out, making a draught past the bullet of the most tremendous intensity tending obviously to drive it forward. While this draught does most assuredly hurry the bullet on its forward course, it does not tend to make it spin round any faster. Now if the bullet were not hurried on at all after it left the muzzle it would, travelling as in a screw of the same pitch all the way from the breach of the rifle up to the point at which it is photographed, have turned round a certain number of times which depend upon the distance travelled and the pitch of the screw. If, however, the longitudinal motion is hurried and the rotational is left unaltered the pitch will be lengthened outside the barrel and the rotation will have been less for any position than it would have been if the bullet had not been accelerated in this way. If, therefore, we can find to what extent the bullet has turned actually at the place at which it has been photographed, we can find the apparent rotational lag and so working backwards get a measure of the velocity acquired after leaving the muzzle. In order to accomplish this I drilled a series of holes transversely through the bullet, each one at an angle to the previous one, the whole series being such that to whatever extent the bullet had twisted, one at least, and perhaps two, would allow the light of the spark to shine through it upon the photographic plate. Then from the photograph it is easy to see through which hole the light shone, and knowing in what position this was in the breach, it is easy to find what fraction of half a turn over or above any whole number of half turns the bullet has twisted. Strictly the measure should be made at different distances to eliminate all uncertainty, but the only shot I have taken was sufficient to show that there was a rotational lag equivalent, according to the measure made by Mr. Barton, to something under a two per cent. acceleration outside the barrel. I do not attach any importance to this figure; the experiment was made with a view to see if the method was practicable and this it certainly is. I would recommend, where accuracy is required, that having found as above about how much the

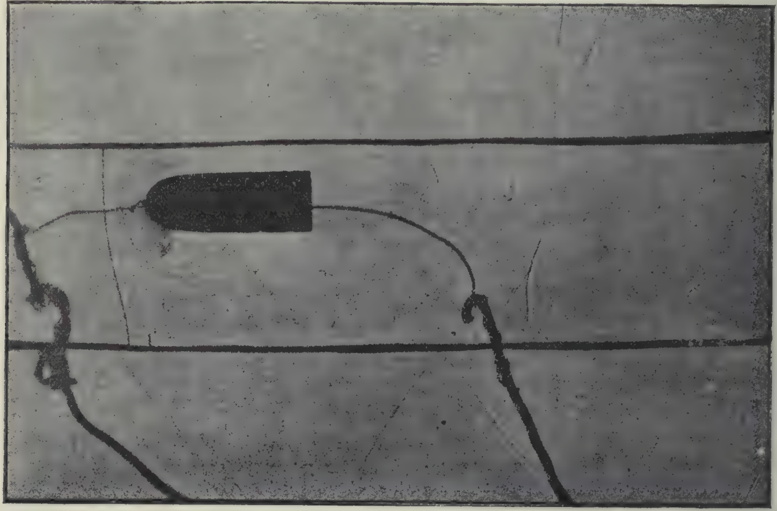

Fig. 12.

bullet has turned, that a second bullet should be drilled with a series of holes at about the corresponding position differing very slightly from one another in angular position, so that several would let the light through and thus give a more accurate measure of the rotation.

There is a point of interest to sportsmen which has given rise to a controversy which the spark photographs supply the means of settling. The action of the choke bore has been disputed, some having held that the shot are made to travel more compactly altogether, while others, while they admit that the shot are less scattered laterally, as may be proved by firing at a target, assert that they are spread out longitudinally, so that if this is the case the improved target pattern is no criterion of harder hitting, especially in the case of a bird flying rapidly across the direction of aim.

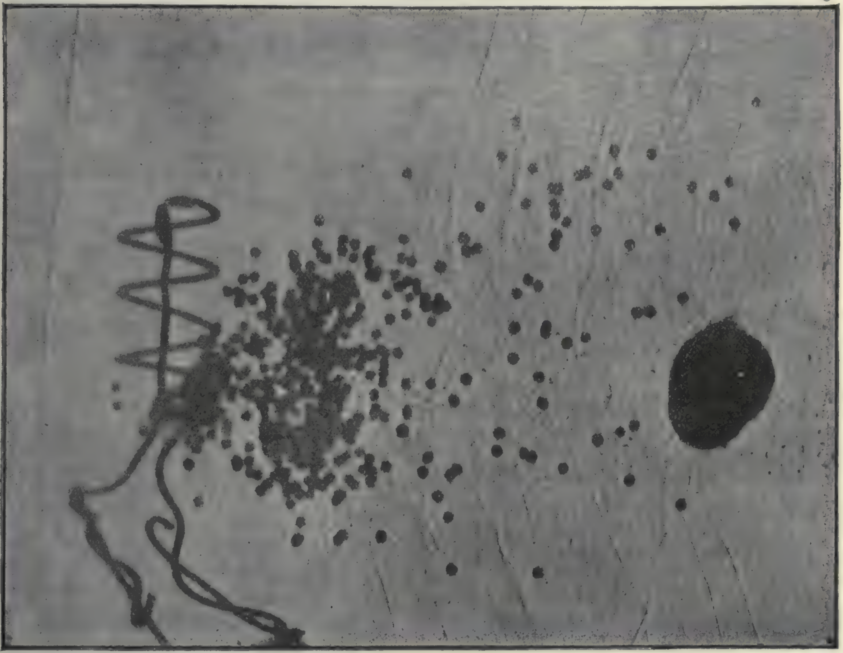

Fig. 13.

I was unfortunately not able, in the limited space and time that I have been able to employ, to take photographs of the shot at a reasonable distance from the gun, but I have taken comparative photographs at three or four yards only in which every shot is clearly defined, and in which it is even easy to see on the negative where the shot have been jammed into one another and dented. The difference in the scattering at this short distance is not sufficient for the results to give any information beyond this, that shot are as easily photographed as bullets, and that no difficulty need be apprehended in attempting to solve any question of the kind by this method. The photograph, Fig. 13, represents the shot from the cylindrical or right-hand barrel. The velocity now is so low that individual waves are no longer formed by each shot. The whole space, however, occupied by the shot is filled with air waves of the greatest complexity. They are not due to the cause already explained, but are, I believe, formed by the imperfect mixture of air with powder gases still accompanying the shot. The imperfect mixture of the two gases causes light to be deflected in its passage, thus producing striæ just as at the first mixing of whisky and water, striæ are seen (sometimes attributed to oil !), which disappear when the mixture is complete. I would mention, for the benefit of any one who may be tempted to continue these experiments, that a pair of wires such as are found to do so well when bullets have to be caught are not suitable, as one is sure to be shot away before such a bridge of shot is made between them as will allow a spark to pass. However, by using thick copper wires, one bent in the form of a screw, with the other along the axis, no such failure can occur and every shot that I have taken in this way has been successful. One can of course test the action of any material mixed with the shot. For instance, in one case I mixed a few drops of liquid oil with the shot and found them more widely scattered in consequence, not, as has been stated, held together by the oil as if they were in a wire cartridge. Of course, solid grease or fat may, and no doubt does, produce such a result, but liquid oil certainly does not.

And now I wish to conclude with a series of photographs which show how completely the method is under control, how information of a kind that might seem to be outside the reach of experiment may be obtained from the electric spark photograph, and how phenomena of an unexpected nature are liable to appear when making any new experiment. The result, however, is otherwise of but little interest or importance.

I thought I should like to watch the process of the piercing of a glass plate by a bullet from the first shock step by step, until the bullet had at last emerged from the confusion it had created. In Fig. 14 the glass plate is seen edgeways just after the bullet has struck it. It is clear at once that the splash of glass dust backwards is already four or five times as rapid as the motion of the bullet forwards. A new air wave is just beginning to be created in front of the glass-coated head of the bullet and two highly-inclined waves, one on either side of the glass, reaching about three-quarters of the way to the edge, have sprung into existence. These are more clearly seen in the next figure; meanwhile it may be well to point out that the fragments of paper which are following the bullets have in this case—as the card was much nearer to the glass plate than in those previously taken—some of them lost so much of their velocity and have in consequence lagged behind in a still higher proportion than the others, that they are travelling at less than 1100 feet a second; the more backward ones carry in consequence no air waves and there is no means of telling from the photograph that they are moving at all. In Fig. 15 the bullet has struggled about half way through the plate. The waves on either side of the plate have now reached the edge and are on their way back towards the centre again. They are caused in this way. When the bullet strikes the plate the violent shock produces a ripple or tremor in the glass which travels away radially in all directions, leaving the glass quiet behind. The rate at which this ripple travels may be found from the angle which these new air waves make with the plate, for taking any point on the plate and measuring up to the point where the air wave meets the plate and also the distance in air to the nearest point of the inclined air wave, we get two distances, the ratio of which is the ratio of the velocity of the disturbance in the glass to the velocity of sound in air. But much more than this is shown. An examination of the negatives or of a photographic print and even, but less clearly, of the print in the text shows that these inclined air waves are made up of a series of dark and light lines at a very slight inclination to the air wave itself, so that as we travel

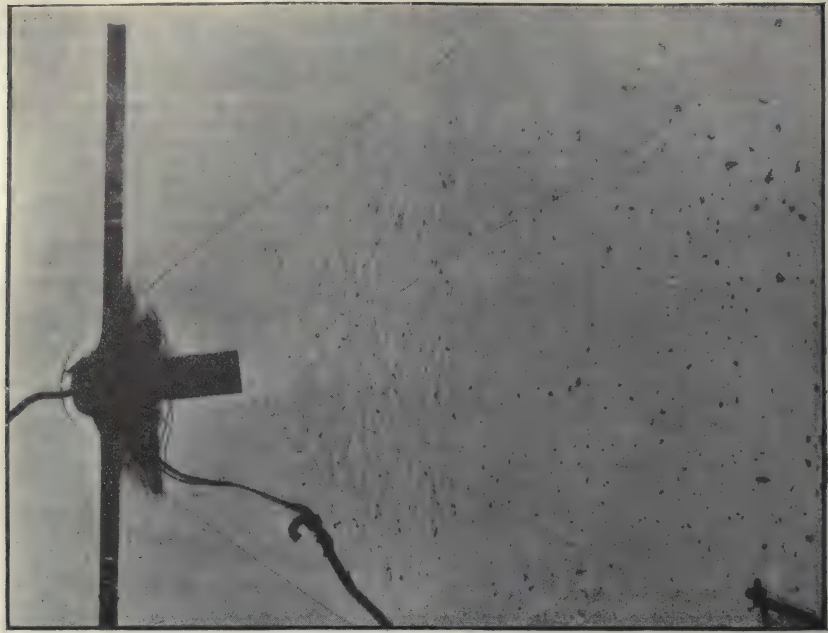

FIG. 14.

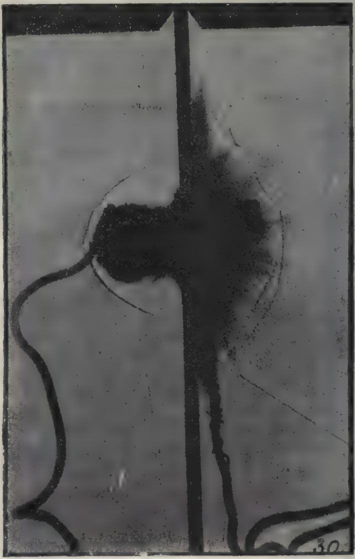

FIG. 15.

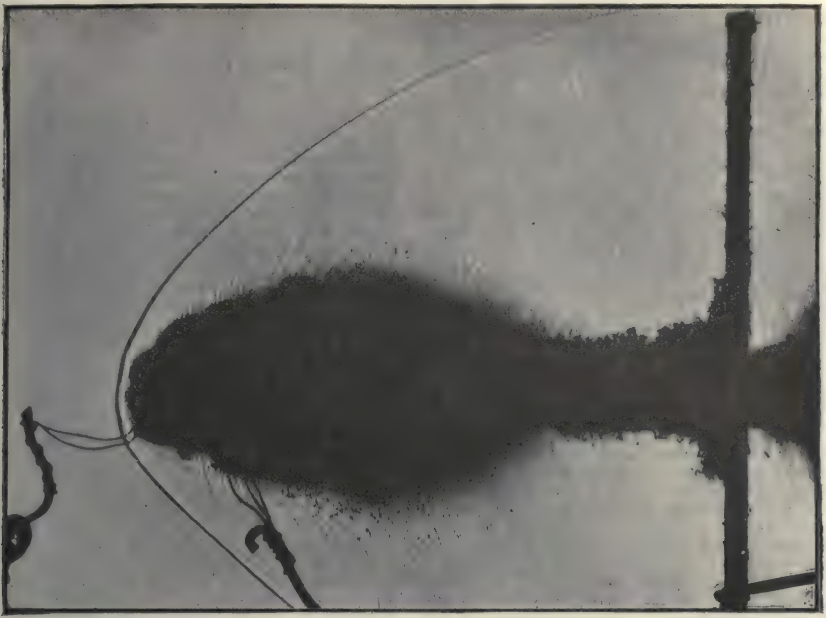

Fig. 16.

along the air wave it is alternately dark outside and light outside. These indicate the successive positions in which the glass first moved outwards to compress the air or first moved inwards to rarefy it so that the wave length of the ripple may thus be found, and finally it is seen that where the waves are waves of compression on one side of the plate they are waves to rarefaction on the other, indicating that it was a transverse and not a mere longitudinal disturbance that ran along the plate from the centre outwards and back again after reflection from the edge. In addition to this the fact that the reflected wave is still on its inward course proves that up to this time the plate is whole, as a wave cannot be propagated in a broken plate. Fig. 16 illustrates the state of affairs when the bullet has travelled about five inches beyond the plate. It has not yet emerged from the cloud of glass dust. The new head wave is very conspicuous. In the original negative, about half way between the bullet and the plate, the inclined waves due to the tremor in the glass plate may be detected, but they are too delicate to be reproduced by the printing process. They supply the information as to how long the plate remained whole or rather if the bullet had been caught a little sooner before these faint waves had lost so much of their distinctness they would supply this information with great exactness. Meanwhile the figure shows that the plate is now broken up completely. It is true it is still standing, and the stern air wave is seen reflected from the upper part of it, but this is because the different parts have not yet had time to get away; their grinding edges, however, have cast out from the surface little particles, and these are seen over the whole extent of the plate. After about fifteen inches the bullet is quite clear of the cloud of dust (Fig. 17); one piece only of the glass, no doubt the piece that was immediately struck, has been punched out and is travelling along above the bullet at a speed practically equal to its own. I am also able to show the plate itself in this and a still later stage, when at last the separate pieces have begun to be visibly moved out of their position and in some cases slightly turned round.

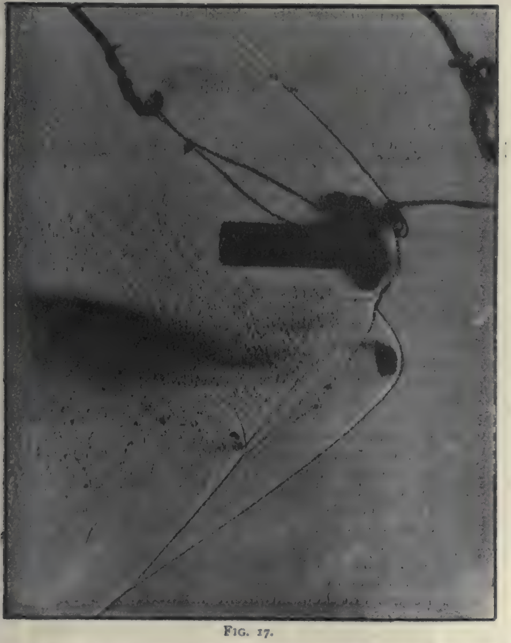

Fig. 17.

I have merely given this evening an account of a few experiments which in themselves perhaps are of little interest, but they at any rate show the capability of this method for the examination of subjects which would in the ordinary way be considered beyond the reach of experiment. It is hardly necessary to say that the examples given by no means reach the limit of what may be done, I have examined the explosions produced by fifteen-grain fulminate of mercury detonators and of heaps of iodide of nitrogen, a material which is rather unmanageable, as if a fly even walks over it it violently explodes. In these cases the explosive flash was used to make the B gap of Fig. 4 conducting, for which it answered perfectly. One might in the same way examine the form of the outrush of powder gases past the bullet, and so find at once their velocity with respect to the velocity of the bullet, and I see no great difficulty in tracing, if this should be desired, the whole course of a single bullet for perhaps as much as 100 yards by means of photographs taken every few inches on its way. Though it may not be evident that these or similar experiments are of any practical importance, there can be no doubt that information may be readily obtained by the aid of the spark photograph, as in fact has been shown by Prof. Mach, Lord Rayleigh, Mr. F. J. Smith, and others, which without its aid can only be surmised, and that if, as in other subjects, the first wish of the experimentalist is to see what he is doing, then in these cases surely, where in general people would not think of attempting to look with their natural eyes, it may be worth while to take advantage of this electro-photographic eye.

I wish in conclusion to express my obligation to the gentlemen to whom I have already referred, to Messrs. Chapman and Colebrook for their assistance, and to Messrs. Moore and Grey for having supplied me with weapons and ammunition.

MICRO-ORGANISMS AND THEIR INVESTIGATION.[1]

As the field of bacteriological investigation becomes extended, we have of necessity constant additions to the various methods rendering possible the pursuit of researches in these novel directions. We have only to look at the first edition of Hueppe's "Methoden der Bakterien-Forschung," published in 1885, consisting of 174 pages, and compare it with the bulky volume of 488 pages which forms the fifth edition, to see at a glance the advance which has been made in the matter of methods alone. In Flügge's "Die Mikro-organismen" we have another type of book, dealing exclusively with micro-organisms themselves, and the information which has been gathered together concerning them, whilst all details of bacteriological practice are purposely omitted. Dr. Günther has attempted a welding together of these two types of book, special attention being given to microscopical technique with which his name is indeed more particularly associated.

The first part is devoted to a survey of our knowledge concerning bacteria in general, commencing with the earliest observations of Leeuwenhoek in 1683. In this review we find an account of their morphology, the principles upon which their classification is attempted, &c., together with a detailed account of the most recent methods for their cultivation and subsequent study, including careful directions for the use of the microscope, and a most elaborate description of the available means for staining bacteria.

The second part is confined to a consideration of the best-known pathogenic and non-pathogenic micro-organisms.

There could not be a more admirable account of the numerous manipulations involved in bacteriological investigations; all the minutiæ are described with the utmost care, and what is usually left for the student to learn in "profiting by his experience" is here carefully anticipated, and if he tumbles into any pitfalls, it is not because he has been without warning.

With such a big task as Dr. Günther has set himself it is not surprising to find some parts less amply dealt with than they would seem to deserve. Thus we find but a very meagre supply of culture media given, there is no mention of the preparation of milk, or of the special solutions employed by Pasteur, Naegeli, and others, neither is there any account of Kühne's silica jelly, which since our knowledge of the fact that certain organisms will only flourish in media devoid of all organic matter, ought surely to have been included.

On the other hand a minute description is given of gelatine-plate, dish and tube cultures, as well as of the most modern methods for the anaërobic cultivation of bacteria, &c. In connection with the abstraction of certain colonies from gelatine-plates, mention may be made of a piece of apparatus (the description of which was only published after Dr. Günther's book appeared) originally devised by Fodor, and called "Bakterien-Fischer," which has been, under the name of "Bakterienharpune," more recently modified and considerably cheapened by Unna. Every one has experienced the difficulty of fishing out a particular colony in a crowded plate, how it is almost impossible to look through the microscope and fix upon the centre to be abstracted, and at the same time keep the needle steady and ensure touching only the one colony which is required By using the above contrivance, which can be attached to the microscope, the fishing out of such centres is greatly facilitated.

The examination of air for micro-organisms is only very slightly touched upon, as is also the bacteriological investigation of water. It is a little rash to assert that "pathogenic micro-organisms can live for a long time in sterilised water," considering that it has been shown in some cases that their *immersion* only is sufficient to destroy them. Again, no mention is made of Hansen's special methods for the examination of particular waters; although they are opposed to the Koch school, this ought not to preclude a reference to what has been proved by a large number of investigations to be, in some cases, of great practical utility.

The second part opens with a short introduction, in which the nature of pathogenic organisms in general is described, and an account given of the rigid proof which is required before a particular organism may be said to be the cause of a particular disease. Protective inoculation and immunity are briefly referred to, and Metschnikoff's brilliant theories of phagocytosis summarily dismissed, and declared incapable of standing the test of the "careful experimental criticism to which they have been submitted by Flügge, Baumgarten, and the author's own pupils."

As many as twenty-seven different varieties of micro-organisms are described in the section on the most important pathogenic bacteria. Amongst these we find the micro-organisms associated with anthrax, tuberculosis, diphtheria, cholera, pneumonia, tetanus, typhoid fever, and chicken-cholera, more especially dealt with, an exceedingly useful and comprehensive summary being given in each case of what is known concerning them, together with numerous references to original papers published on the subject. That Dr. Günther is an ardent disciple of Koch's will at once be admitted, when we read the terms in which he speaks of the *Tuberculinum Kochii*: "Eine neue Aera begann nicht allein für die Tuberculoselehre, sondern für die gesammte Medicin, mit der grossen Entdeckung Koch's der Heilung der Tuberculose."

---

[1] "Einführung in das Studium der Bakteriologie." By Dr. Carl Günther. Second Edition. (Leipzig: Georg Thieme.)
"Technique Bactériologique." By Dr. R. Wurtz. Encyclopédie Scientifique des Aide-Mémoire. (Paris: Gauthier-Villars et fils, 1892.)

Amongst the non-pathogenic forms we find an account of the *Micrococcus agilis*, which was found by Ali-Cohen in drinking water. This was not the first motile coccus found, as is stated by Günther, for previous to this, Mendoza isolated and described a motile form which he called *Micrococcus tetragenus mobilis ventriculi*. The *Micrococcus agilis* was the second variety found; whilst later, in 1890, Loeffler also discovered and described a motile coccus. It is surprising, therefore, to read that Ali-Cohen's variety is the only motile micrococcus known. The list has further been quite recently (1892) enriched by the discovery by Maurea of a motile sarcina, which he has designated *Sarcina mobilis*.

A fine set of seventy-six photographs, mostly taken from original preparations, together with a very exhaustive index, completes the volume. Amongst the photographic figures the series of twelve representing anthrax in every stage of development from the individual bacteria to their appearance as colonies on gelatine-plates, and growing in test-tube cultivations, are particularly beautiful; the surface colonies photographed after forty-eight hours' growth are especially characteristic and successful.

In the handy little volume "Technique Bactériologique," of Dr. Wurtz, chief of the laboratory for experimental pathology in the Faculty of Medicine in Paris, we have an entirely different stamp of book. We read in his preface: "On ne trouvera, dans ce précis de Technique bactériologique, ni l'historique, ni l'exposé detaillé des nombreuses méthodes techniques qui ont été préconisées jusqu'à ce jour en microbiologie. Conformément au programme tracé par la Direction de *l'Encyclopédie Scientifique des Aide-Mémoire*, nous nous sommes efforcés d'éxposer, aussi clairement que possible, les notions qu'un débutant doit posséder à fond avant d'aborder l'étude proprement dite des microbes."

Proceeding on these lines Dr. Wurtz gives us a very clear and precise account of all the various important stages passed through in bacteriological manipulations, commencing with a chapter on the principles of sterilisation.

But a novel feature in this volume is the description of the various methods of conducting experiments on animals for bacteriological purposes. This is carefully recorded and supplemented by woodcuts, and would appear to be a most useful addition, for although the possibilities of carrying out such experiments in this country are very limited, yet in those cases where they are permitted such an accurate description of the methods to be adopted should prove very helpful, more especially as in very few of the German and English bacteriological text-books is any account to be found for the information of those desiring to undertake such investigations. A chapter is also devoted to the enumeration of the substances, in as far as they have been investigated, which are elaborated by micro-organisms and a description of the most convenient methods for their successful extraction.

The crisp and concise language which characterises the book, together with the judgment displayed in its compilation, show that the author possesses, not only a full grasp of his subject, but is also highly skilled in the art of communicating it to others.

GRACE C. FRANKLAND.

THE ORDNANCE SURVEY.

A DEPARTMENTAL committee was appointed by the Board of Agriculture in April, 1892, to inquire into the condition of the Ordnance Survey. The committee consisted of Sir John E. Dorington, M.P. (chairman), Sir Archibald Geikie, F.R.S., Mr. Henry W. Primrose, Mr. William Mather, M.P., Mr. H. J. Roby, M.P., and Mr. Charles Fortescue Brickdale, with Major Duncan A. Johnston, R.E., as secretary. The matters referred to then were:—

1. What steps should be taken to expedite the completion and publication of the new or revised one-inch map (with or without hill-shading) of the British Isles?

2. What permanent arrangements should be made for the continuous revision and speedy publication of the maps—1 in 500 (towns), 25 in., 6 in., and 1 in. scales?

3. Whether the maps as at present issued satisfy the reasonable requirements of the public in regard to the style of execution, form, information conveyed, and price, and whether any improvement can be made in the catalogue and indexes?

After the appointment of the committee Mr. T. Ellis, M.P., asked in the House of Commons a question which showed that there was dissatisfaction with regard to the inaccuracy and incompleteness of the names of places in the map of Wales; and this question was also referred to the committee.

The report of the committee has just been issued, and includes the following recommendations:—

1. That the 1 in. map be produced in the following forms:—
(*a*) An engraved outline map, with contours in black.
(*b*) A black engraved map, with hill-shading either in black or in colour.
(*c*) A coloured map on thin paper, adapted to military purposes, but also on sale to the public.
(*d*) A cheap map by transfer to zinc or stone.

2. That the character of the roads on the 1 in. map be shown in four classes with distinct characteristics.

3. That parish boundaries be omitted from the 1 in. map.

4. That the contours of the sea bottom round the coast line and the depths of inland waters be shown.

5. That experiments be made in the practical application of heliogravure, and that, if results not inferior to an Austrian specimen map which we have seen be produced, that process be substituted for the existing method of engraving hills, and for so much of the country as is then uncompleted in its hill engraving.

6. That special arrangements be made to revise the 1 in. map within the next four years independently of the maps on the larger scales, and that subsequently this map be constantly revised within periods of fifteen years.

7. That the cadastral maps be revised and brought up to date in the next ten years, and that subsequently they be kept revised within periods of fifteen years.

8. That the publication of these revised maps be carried out by contract, if necessary.

9. That detail, such as single trees, footpaths in gardens, &c., be omitted.

10. That the skeleton and coloured forms of the 25 in. and town maps be abandoned, and the uses of both be combined in one edition having the houses cross-hatched.

11. That the reference numbers to parcels of land on the 25·344 in. plans be abandoned on revision.

12. That to a limited extent additional contour lines be added to the 6 in. map.

13. That on the 6 in. map the contours be always in black.

14. That certain of the engraved plates of the 6 in. map which are not now filled up beyond the county boundary be as soon as possible filled up to the margin of the plate with the detail of the adjoining county.

15. That the cost of the engraved sheets of the 6 in. map and that of the quarter-sheets of the photo-zincographed 6 in. map be equalised by a change of their respective selling prices.

16. That the Welsh names be gone over and corrected before the first revision of that map.

17. That the cadastral maps on the town scales be no longer entirely made or revised at the cost of the State, but that the town authorities be required by statute to maintain these maps.

18. That around towns and in tourist districts the existing sheets of the Ordnance Survey on the 6 in. and 1 in. scales be united so as to form special maps of such districts, and that advantage be taken of these maps to introduce any novelties in cartography that may be thought desirable, as these maps are not required to be joined to the general maps of the United Kingdom.

19. That certain authorities be placed under statutable

obligation to supply information to the Ordnance Survey Department in order to enable current revision to be better carried on.

20. That in future the term "revision" should be confined to the bringing up to date on its existing scale of a map already published, and that the term "resurvey" be applied to the operations necessary for the production of maps on a scale larger than that on which they were originally published.

21. That the Ordnance Survey Department be allowed to control its own supply of paper and printing material.

22. That the map on the scale of four miles to an inch be revised as soon as the 1 in. map is out of hand, and be completed with hill-shading.

23. That great freedom be allowed to private publishers desirous of bringing out other classes of maps than those specially published by the Survey Department, and that transfers of the maps on the 1 in. and smaller scales be supplied to publishers at cost price, a small sum being paid as an acknowledgment, and that all other reproduction of Ordnance Survey maps be prohibited.

24. That certain recommendations as to indices and catalogue be carried out.

25. That a book or pamphlet of information as to the Ordnance Survey be published, general in its main features and special for each county, containing the county indices or diagrams (on a reduced scale) and the information formerly contained in the parish area books, and also the table of parish areas now printed on the index of the 6 in. map, which table should in future be omitted from that map, and that copies of the small indices in this pamphlet be freely distributed for public information.

NOTES.

OWING to the large demand for tickets for the Croonian Lecture, which is to be delivered by Prof. Virchow before the Royal Society and their friends next Thursday, it has been decided to hold the meeting in the theatre of the London University, which has been lent for the occasion by the kind permission of the Senate.

THE public dinner which is to be given in honour of Prof. Virchow will be held on March 16, after the delivery of the Croonian lecture, at the Hôtel Métropole. Lord Kelvin will preside, and will be supported by the Presidents of the Royal Colleges of Physicians and Surgeons as vice-chairmen.

AT the Nottingham meeting of the British Association, over which Prof. Burdon Sanderson will preside, Lord Salisbury will be nominated president of the Association for the Oxford meeting in 1894. The following gentlemen have consented to act as presidents of sections at Nottingham:—Section A, Mathematical and Physical Science, Prof. Clifton, F.R.S.; Section B, Chemistry and Mineralogy, Prof. J. Emerson Reynolds, F.R.S.; Section C, Geology, Mr. J. J. H. Teall, F.R.S.; Section D, Biology, the Rev. Canon Tristram, F.R.S.; Section E, Geography, Mr. Henry Seebohm, Sec. R.G.S.; Section F, Economic Science and Statistics, Prof. J. S. Nicholson; Section G, Mechanical Science, Mr. Jeremiah Head; and Section H, Anthropology, Dr. Robert Munro.

AT the ordinary meeting of the Royal Meteorological Society, to be held at 25, Great George Street, Westminster, on Wednesday, the 15th instant, at 7 p.m., a lecture will be given by Mr. Shelford Bidwell, F.R.S., on some meteorological problems, which will be illustrated by experiments.

DR. R. THORNE THORNE, Medical Officer of the Local Government Board, and Mr. H. Farnall, of the Foreign Office, have gone to Dresden, the former as British delegate to the International Sanitary Conference in that city, the latter as assistant delegate.

THE students of the Royal College of Science propose to hold a conversazione in the South Kensington Museum on the evening of March 23 next. In the course of the evening Mr. Boys, F.R.S., will deliver a lecture on soap bubbles, illustrated by his own interesting experiments. The evening will be further enlivened by various public singers, and a selection of music will be played by the band of the Grenadier Guards.

IN reply to a question put by Sir Henry Roscoe in the House of Commons on Friday last with regard to the proposed new buildings for the Royal College of Science, Mr. Shaw Lefevre said:—"The accommodation at the Royal College of Science is now undoubtedly inadequate, and in my opinion new buildings must be undertaken at some early opportunity. Block plans were drawn up in 1891 by the professors of the Royal College of Science, showing a suggested appropriation of the land on the south side of the Imperial Institute Road, for the purposes both of the Royal College of Science and of the Science Museum, and these plans were submitted to the Office of Works; but that Department pointed out that it would be premature for them to consider the plans until the Science and Art Department had obtained the sanction of the Treasury to an organisation of their teaching and exhibition establishments on the scale contemplated in the plans. I understand that the Science and Art Department are now in communication with the Treasury in this sense." Sir H. Roscoe having asked when the report from the Science and Art Department would be issued, Mr. Shaw Lefevre said it was not in the nature of a report that could be issued to Parliament, but he should be happy to show it to the hon. member.

LAST week a meeting, convened by the Duke of Westminster as president of the Royal Agricultural Society, was held at 12, Hanover Square, to consider the best means of commemorating the completion of the first half-century of the agricultural experiments which have been continuously carried on by Sir John Lawes at Rothamsted since the year 1843. The Prince of Wales presided. On taking the chair his Royal Highness stated the objects of the meeting. The Rothamsted experiments had from the commencement been entirely disconnected with any external organisation and had been maintained at the sole cost of Sir John Lawes. For the continuance of the investigations after his death Sir John had recently made the munificent endowment of £100,000, besides the famous laboratory and certain areas of land, and had nominated some of the most distinguished men of science of the day to administer the trust. In view of all these facts, and the great national importance of the Rothamsted experiments, it was only fitting that some public recognition should be made of the invaluable services rendered to agriculture by Sir John Lawes and his distinguished colleague, Dr. Gilbert. The Duke of Westminster said they all hoped that Sir John might live for many years to continue to carry on these experiments for the benefit of agriculture. He had great pleasure in proposing the following resolution:—"That, having regard to the great national importance of the series of experiments which have been carried on at Rothamsted during the last fifty years, it is desirable that some public recognition should be made of the invaluable services thus rendered to agriculture by Sir John Lawes, and also by Dr. Gilbert, who has been associated with the experiments during the whole period. That, with this object, subscriptions, to be limited to two guineas, be invited from all interested in agriculture, whether scientific or practical." Mr. Thiselton-Dyer, F.R.S., seconded the resolution—not as an agriculturist, but as one officially and all his life deeply interested in everything that was concerned with botanical science. The extraordinary merit of the work carried on at Rothamsted lay in the fact that those experiments had been continuously carried on under uniform conditions for so long a period. He ventured to say, as a scientific man, that he knew nothing in the whole records of scientific research more honourable to this country than those experiments which were being carried on at Rothamsted with such self-denying skill. The resolution was then put by the chairman, and carried unanimously. Sir John Evans moved :—"That, in the opinion of this meeting, the testimonial might advantageously take the form of —(1) a granite memorial, with a suitable inscription, to be erected at the head of the field where the experiments have taken place; (2) addresses to Sir John Lawes and Dr. Gilbert, accompanied (if funds permit) by a commemorative piece of plate." This was also carried, and it was unanimously resolved that the following should be requested to act as a committee for carrying the resolutions into effect :—The presidents of the Royal, Royal Agricultural, Linnean, and Chemical Societies, the Earl of Clarendon, Viscount Emlyn, Sir John Lubbock, Sir John Evans (hon. treasurer), and Mr. Ernest Clarke (hon. secretary), with power to add to their number. The Duke of Westminster moved a vote of thanks to the chairman, and the Prince of Wales said, in response, that nothing had given him greater pleasure and satisfaction than to take the chair on that occasion, and to testify, as an agriculturist, his own sense of gratitude for what Sir John Lawes had done for agriculture. Subscriptions to the fund may be sent to any member of the committee, to Sir John Evans, F.R.S., at Nash Mills, Hemel Hempstead, or to Mr. Ernest Clarke, at 12, Hanover Square, W.

LORD SALISBURY presided over a meeting held at Oxford last week, in aid of the building fund of the Radcliffe Infirmary. He delivered a most vigorous address, in the course of which he said that at Oxford the difficulty connected with medical education was the reverse of that felt in London. In London the practical opportunities of exercising medicine were abundant, and the only care, or the main care, which pressed upon those who had charge of education in that respect was lest the more scientific basis of that practice should be neglected or receive inadequate attention. At Oxford, on the contrary, they had abundant means of teaching the group of sciences which were the equipment of the physician. But, necessarily, unless they made a great effort to that end, they should not have the means of presenting those opportunities of practical inquiry which were essential to the formation of the professional ideal, and which in large populations necessarily occurred with so much greater frequency. This movement—for so he looked upon it—on the part of the rulers of the University, to draw somewhat closer to the science of medicine, was only part of a larger movement which had been going on for some time, which, if he might use the scientific language of the day, was part of the evolution of education in our time. He begged to assure the assembly that he had no traitorous views with respect to the study of Greek. In fact he was inclined to say that in recent controversies the advocates of the classical languages had been unduly frightened, and that there was not the slightest danger that the study of them would ever pass from the education of youth or the culture of men of intellect. The issue was not between science and languages, ancient or modern; the issue rather was between the science whose chief food was gathered from observation and the science whose chief food was gathered from reflection. This older science was slowly, very slowly, but still quite evidently, giving way to the sciences which relied upon observation. He always thought that the science of medicine had scarcely received among us all the tribute which it ought to receive among sciences which rest upon observation. It was a curious fact that the whole tendency of scientific thought appeared to be rapidly concentrating itself upon the fields in which medicine reigned supreme. Those infinitely minute beings which certainly for health or sickness deeply affected our existence, and which were so essential to us that some able scientific men said that we consisted of nothing else, that we were not only a Republic, but were in a permanent state of civil war—these bacilli were attracting more and more the attention of the scientific intellect in Europe. It was dangerous to prophesy, but he did not think that any one who had watched the course of science would doubt that for the generation to come the investigation of these creatures, which had been revealed by new methods of research and by singularly patient labour, and upon which the lives of millions of human beings depended, would figure more largely in the scientific field than any other study. This was the special domain and privilege of medicine. He felt, therefore, that in commending this appeal to their consideration he was doing more than preaching a charity sermon. He was asking them to help that which contained the most brilliant promise for the intellectnal future of science in a University by which science ought to be cultivated and where science ought to reign.

AFTER Lord Salisbury's address various resolutions were adopted, among which was one, moved by Prof. Dicey, to the effect that the Radcliffe Infirmary, being the chief hospital for Oxford and a large surrounding district, should be brought into a state of efficiency corresponding with the recent advances in hospital management. Another resolution, moved by the Master of University, expressed approval of the committee's scheme, consisting of the removal of the sick from the old building into more modern wards and the renovation of the old building.

ON Saturday and Sunday last much damage was done in Sandgate, near Folkestone, by remarkable disturbances of land. The first disturbance was felt on Saturday at 7.45 P.M., when a rocking motion was noticed. This soon stopped, but later disturbances were so alarming that many people took their furniture into the streets. According to a correspondent of the *Times*, houses "slipped away from each other, leaving gaping sections," while in other cases the walls bulged out, and great rifts appeared in the ground. In the area affected by the disturbances most, if not all, of the houses are out of line and show cracking. Many of the inhabitants have been brought to great distress by the calamity, and appeals to the public have been issued on their behalf. An inquiry into the cause of the disaster was held at Sandgate on Tuesday by Mr. Walton, Local Government Board Inspector. After hearing evidence the Inspector said that an official report would be sent to the Board. What he had seen led him to conclude that the catastrophe was due to the sudden release of impounded subsoil water, a thing which he believed was remediable by the institution of proper water drains. If that was attended to there was no reason to suppose that such a disaster would ever recur. The *strata* were full of water, which the recent abnormal rainfall had served to increase. That water being released had formed kinds of caverns. The remedies were proper storm drains and intercepting drains, with free outlets under the road to the sea.

THE death of Ludwig Lindenschmit, the well-known German archæologist, is announced. He died at Mainz on February 14 in his eighty-fourth year. He was the director and one of the founders of the fine Central Romano-German Museum at Mainz, and one of the editors of the "Archiv für Anthropologie." Among his works are "Die vaterländischen Altertümer der fürstlichen Hohenzollernschen Sammlungen" and his "Altertümer unserer heidnischen Vorzeit." He began a "Handbuch der deutschen Altertumskunde," but completed only the volume relating to the Merovingian period. Lindenschmit was an enthusiastic advocate of the theory that the Aryan race is of European origin.

THE temperature during the past week has been generally very high for the season, the daily maxima frequently exceeding

55°, and even reaching 59° in the eastern counties on Sunday; whereas the average maxima for the month, deduced from twenty years' observations at the telegraphic reporting stations of the Meteorological Office, range from about 45° in the north to 50° in the south and south-east. During the latter part of last week several depressions skirted our north-west coasts, and rain fell generally every day, although the amounts measured were not great; but on Sunday the type of weather changed, especially over the southern part of the kingdom. An anti-cyclone advanced over our south-west coasts from the Atlantic, while the air became dryer and conditions more settled, although there was little sunshine in any part of the kingdom. There was a deep depression over Norway on Tuesday, while secondary depressions in connection with it were approaching the north-west of Scotland, and occasioning a return of stormy weather in the northern parts of these islands. From the *Weekly Weather Report* it appears that for the week ending the 4th instant the rainfall was above the average in all districts except the north of Scotland and the south of Ireland. Over the northern parts of England and the east of Scotland the excess was large, owing chiefly to heavy snowfall at the beginning of the period.

AMONG the various marine zoological stations which, on the initiative of that at Naples, have sprung up in recent years, the station at Trieste, on the Adriatic, holds an honourable place. It has been in existence nearly eighteen years. Dr. Claus states (*Naturw. Rdsch.*) that for its double function of instruction and investigation opportunity is afforded both to students and men of science. The students are, primarily, those of the professors of zoology at Vienna University, to whom the management is entrusted; also those of the Graz professor, who has a right to four places out of twelve. Students of other Austrian Universities are also freely admitted to work, and Austrian and foreign investigators. To each worker the ordinary reagents, besides the table, are supplied gratis; also the material, so far as it can be provided without special cost. The station further supplies living and preserved marine animals as specimens to the Zoological Institutes of the Vienna and Graz Universities, sending thither about 120 to 140 specimens annually. Other institutes are supplied on payment as arranged. The number of workers at the station has gone on increasing since it was opened in 1875. Of foreign investigators who have used it may be named Metschnikoff, Kowalevsky, A. Schneider, Selenka, R. and O. Hertwig, Keller, E. van Beneden, Fromann, Braun, and F. Cohn. The results of work carried on there are sometimes published independently, but they chiefly appear in the *Arbeiten* of the Zoological Institute of Vienna University, and the Zoological Station in Trieste, of which ten volumes have appeared. The *Denkschriften* and *Sitzungsberichte* of the Vienna Academy and the German zoological journals also witness to the activity of the station. The Austrian Government has liberally aided this useful institution.

THE new number of the Journal of the Institution of Electrical Engineers contains a report of some very interesting speeches on a paper by Dr. Fleming on experimental researches on alternate-current transformers. The same number includes Mr. Preece's presidential address, from which we have given some extracts. The vote of thanks to the president for his address was proposed by Mr. Spagnolletti and seconded by Sir Henry Mance. Sir Henry said there was one point in the address which had struck him with dismay. That was the gradual increase of the teredo in the neighbourhood of our shores. This fact had been brought home to him that day by specimens of cable recently attacked by "the insect, or mollusc"; and it should teach them—what Mr. Preece had told them many years before—that they should not only survey the bottom of the sea for rocks and shoals, but should also examine it near the shores to find whether it was infested by that pest, which had damaged hundreds of thousands of pounds worth of cable.

THE results of the solar, meteorological, and magnetical observations made during 1892 at the Stonyhurst College Observatory have just been issued by Father Sidgreaves. They take the commendable form of monthly and annual summaries, so that the most interesting results can be seen at a glance, and compared with the mean results of the last forty-five years. The range of barometer readings was only 1·724, or a quarter of an inch lower than the mean, while the range of the thermometer was seven degrees higher than the mean. The extreme range of the barometer recorded at this observatory is 3·13 inches. Sunshine was recorded for 207 hours in June, 202·1 in April, and only 172 in May. From January to April there is a regular increase, and from June to December a regular decrease, the falling-off in May being very conspicuous. 153 drawings of the sun have been added to the already splendid Stonyhurst series. An appendix contains the results of meteorological observations made at St. Ignatius College, Malta.

WE learn from the *Botanical Gazette* that there are now as many as thirty-two botanical stations in the United States carried on by the various State Governments. The subject which receives most attention at these stations is that of the fungus and bacterial diseases of cultivated crops and of fruit-trees, and their treatment and cure. Some of them give attention to systematic botany, while others are investigating the life-history of certain fungi, or carrying on physiological work. A laboratory for the study of plant diseases has recently been fitted up in connection with the agricultural experiment station of the University of California at Berkeley. It has been arranged that a botanical survey of Nebraska shall be undertaken by the Botanical Seminar of the University of that State. The almost unknown flora of the north central portions of Idaho has recently been investigated, as we have already noted, by a commission acting under the auspices of the Botanical Division of the U.S. Department of Agriculture.

IN the first part of Dr. Millspaugh's Preliminary Catalogue of the Flora of Western Virginia, published in the Bulletin of the Agricultural Experimental Station of Morgantown, a new feature has been introduced in a list of the rich fossil flora of the State.

PROF. ANGELO HEILPRIN, of the Peary Relief Expedition, has presented to the Museum of the Academy of Natural Sciences, Philadelphia, the valuable collection of mollusks dredged by him in Greenland waters. They have not yet been studied, but the conservator of the conchological section, in his annual report, says he has ascertained the presence of a number of species not before in the collection of the Academy, of the genera *Margarita*, *Buccinum*, *Sipho*, and other Arctic groups. The specimens preserved in alcohol are in excellent condition for the examination of the soft parts.

MR. J. W. SALTER, writing to the *Zoologist* from University College, Aberystwith, says that on January 4 last he obtained a polecat about six miles south of Aberystwith. There is reason to believe, he says, that the species is by no means extinct in Cardiganshire.

THE Pharmaceutical Society of Great Britain has issued a volume of papers, most of which describe the results of chemical investigations carried on at its Research Laboratory. The editor is Prof. W. R. Dunstan. The papers are reprinted from the Transactions of the societies to which they were communicated, namely, the Royal Society, the Chemical Society, the Pharmaceutical Society, and the Physical Society. Other volumes of a like kind are to follow.

THE new number of the Journal of the Royal Horticultural Society includes, besides papers on many other subjects, reports of conferences on the begonia and on apricots and plums. There is also a long series of extracts from the Proceedings of the society.

THE second part of the excellent "Canadian Guide Book," by Ernest Ingersoll, has been issued (W. Heinemann). It deals with western Canada, and the author has been at great pains not only to collect full and trustworthy information, but to present it in a clear and attractive style. There are maps and many illustrations.

THE results of an investigation concerning the nature and properties of metallic ruthenium, particularly with respect to the fusing point of this highly refractory rare metal, are contributed by M. Joly to the current number of the *Comptes Rendus*. M. Joly has accumulated no less than three kilograms of pure metallic ruthenium, and has consequently been enabled to carry out experiments upon it on a comparatively large scale. It will doubtless be remembered that ruthenium and osmium are the two most refractory of the metals of the platinum group. Deville and Debray only succeeded with great difficulty in obtaining a few minute globules of melted ruthenium with the aid of the oxyhydrogen blowpipe. The fusion of this metal is rendered very much more difficult owing to the readiness with which, at these high temperatures, it becomes converted into the volatile tetroxide RuO_4. It was apparent therefore that in order to attain success the temperature must be suddenly raised to a point considerably higher than the melting point of the metal; and in order to effect this a much more powerful source of heat than the oxyhydrogen blowpipe would be required. M. Joly has therefore employed the electric arc, which has recently been shown by M. Moissan to be so admirably adapted for the preparation of refractory metals. At the high temperature of a powerful arc ruthenium is melted in a few seconds, and without sensible loss by volatilisation in the form of tetroxide. Solid ingots of twenty to thirty grams of the metal have been obtained in this manner without difficulty. As the melted metal cools, however, it becomes covered with a coating of the blue sesquioxide Ru_2O_3 and the dioxide RuO_2. In order to remove this the ingot is placed first in aqua regia, which, however, has no action upon either the metal or the oxides, and subsequently in hydrofluoric acid; finally the ingot is heated in a stream of hydrogen, when it loses the last traces of oxide and the pure metal remains. Pure ruthenium thus obtained in tolerably large quantities after fusion is a greyish-white metal, more nearly resembling iron than platinum in appearance. Its hardness is about the same as that of iridium. It possesses a crystalline structure and is brittle. The density of the metal after fusion M. Joly gives as 12·063 at 0° compared with water at 4°. Employing the same electric arc and under equal conditions in all respects, the fusion of ruthenium appears to be attended with appreciably greater difficulty than that of rhodium and iridium, whose melting points are somewhat higher than the melting point of platinum. Moreover, under the conditions which suffice for the ready fusion of ruthenium, osmium merely sinters, traces of fusion being just apparent. Osmium therefore is the most infusible of the metals of the platinum group. M. Joly is now conducting experiments with the view of determinining the actual temperatures of these interesting high melting points.

NOTES from the Marine Biological Station, Plymouth:—The week's captures include the Lucernarian *Depastrum cyathiforme* and numbers of the Gephyrean *Petalostoma minutum*, Kef. Ephyræ of *Aurelia* have been abundant; Hydroid medusæ scarcer. Polychæte larvæ and *Nauplii* continue plentiful, and *Cyphonautes* (larva of the Polyzoan *Membranipora pilosa*) has considerably increased in numbers. Echinoderm larvæ (*Auricularia, Pluteus*) have made their first appearance in the season's townettings. The Nemertine *Nemertes Neesii* and a large eyeless mud-dwelling species of the Polychæte genus *Polydora* (*flava*, Clap. ?) are now breeding.

THE additions to the Zoological Society's Gardens during the past week include a Black-faced Spider Monkey (*Ateles ater*) from Eastern Peru, presented by Miss Gertrude Farmer; a Macaque Monkey (*Macacus cynomolgus*, ♂) from Java, presented by Mrs. Frank Phillips; a Naked-footed Owlet (*Athene noctua*) European, presented by Mr. Albert Stevens; a Four-horned Antelope (*Tetraceros quadricornis*, ♂) from India, purchased; six Wild Swine (*Sus cristatus*), two Badgers (*Meles taxus*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

COMET BROOKS (NOVEMBER 19, 1892).—The following is a continuation of last week's ephemeris for this comet:—

12h. Berlin Mean Time.

1893.	R A. (app.) h. m. s.	Decl. (app.) ° ′	Log *r*.	Log Δ	Br.
Mar. 9	0 46 27	+20 46·1	0·1842	0·3563	0·47
10	47 22	34·4			
11	48 17	23·0			
12	49 11	12·1			
13	50 4	20 1·5	0·1946	0·3731	0·42
14	50 57	19 51·5			
15	51 49	19 41·0			
16	0 52 41	19 31·2			

This comet will soon be lost in the rays of the sun. The unit of brightness took place on November 21·5, 1892.

COMET HOLMES (1892, III.).—M. Schulhof gives the following ephemeris of this comet for the ensuing week:—

1893.	R.A. (app.) h. m. s.	Decl. (app.) ° ′ ″
March 9	2 43 7·1	35 8 11
10	44 52·2	10 58
11	46 37·2	13 46
12	48 23·4	16 35
13	50 9·4	19 24
14	51 55·7	22 14
15	53 42·2	25 3
16	2 55 29·0	27 53

UNIVERSAL TIME.—On February 6 last the Bill declaring the legal time for Germany to be that of the 15th meridian east of Greenwich, that is, one hour in advance of Greenwich time, passed the third reading. This law will be brought into force on April 1. The *Observatory* for March informs us that, in a letter addressed to the Astronomer Royal, it is stated by Dr. Schran that a similar Bill has been laid before the Austrian Government, and "it is hoped that the change will be made simultaneously with Germany." The draft of the latter Bill, which we take from the same number, provides:—

(1) That the legal time in Austria is the mean solar time of the meridian 15° east of Greenwich. The same to replace, on April 1, 1893, the present local times for legal, civil, and all other purposes.

(2) The Government is authorised to make the changes in the school and industrial hours which will become necessary in consequence of the adoption of the above.

THE BIELIDS, 1892.—M. Bredichin, in *Astronomischen Nachrichten*, 3154, has a short note on the Bielids, in which he says that the observations made in America on November 23 last show that the meeting of the densest part of this swarm with the earth has taken place almost four days earlier than in the year 1885, or, in other words, that the descending node of the stream has receded almost 4° to the west during the period between the end of 1885 and the end of 1892. The cause of this recession is, he says, due to Jupiter, the perturbations set up by this planet accounting for the mean daily motion which is nearly equal to that possessed by Biela's comet.

An approximate computation of the special perturbations for the whole period during which Jupiter had any influence gave for the recession of the node a little over 4°, the inclination decreasing about 0°·6.

THE WOLSINGHAM OBSERVATORY.—In the Report of this observatory for the year 1892 Mr. T. E. Espin tells us that although the zone work was interrupted by attention being given to Nova Aurigæ, yet one hundred and sixteen new Third-Type Stars were detected in zones + 55° and 56°. In the autumn, as the telescope was going to be devoted to the revision of double stars in connection with the new edition of "Celestial Objects for the Common Telescope," the driving clock was taken out and cleaned, and a new arrangement for letting the clock run for one and a half hours without rewinding was also added. Notwithstanding the pressure of work in this direction, as many as eight hundred and forty-seven measures were made in the autumn, "observing being carried on sometimes for twelve hours, and once for thirteen and a half at a stretch." With respect to the new edition of the work mentioned above, Mr. Espin gives a short description of the general scheme. The portions devoted to the planets and the sun (vol. i.) will have several foot-notes added to them, Mr. Denning will write a short chapter on comets and meteors, and chapters on celestial photography and spectroscopic work will also be inserted. The second volume will deal with double stars, &c., and will be entirely rewritten; the objects will be arranged in order of Right Ascension, and all double stars whose primaries are above 6·5 magnitude, and whose distance is less than 20″, will be included. The work of bringing the places up to 1900 was at the end of the year completed for the first twelve hours, and considerable progress has already been made in the next eight hours of Right Ascension. Mr. Espin refers to the death of Miss Compton, who took great interest in the work done at the Observatory, and who left a legacy for the purchase of a photographic telescope. This telescope is already in working order, its aperture being eight clear inches, and focal length forty-two inches, and will be devoted to the photography of the zones observed with the spectroscope for detecting variation in light. The Meteorological Department has also been increased by a hygroscope and solar radiation thermometer, the gifts of Miss Brooke.

UNITED STATES NAVAL OBSERVATORY.—From the report of the superintendent (Capt. F. C. McNair) of this observatory for the year ending June 30, 1892, we gather the following few notes. In October, 1891, owing to the retirement of Prof. Asaph Hall, the use of the 26-inch refractor was tendered to Mr. Asaph Hall, junior, the latter observing the satellite of Neptune, satellites of Saturn, and the two outer satellites of Uranus. During the period of opposition of Mars, in August, 1892, the instrument was employed by Prof. Hall for the purpose of securing measures of the satellites, as the superintendent thought that "it seemed fitting that Prof. Hall, the discoverer of these satellites, should have the privilege of observing them once more under such exceptionally favourable circumstances." With the transit circle practically no observations were made, as the instrument was under repairs previous to being set up in the new observing houses; the Meridian transit, on the other hand, was in constant use, chiefly in connection with the time service. The 9·6 inch equatorial was as usual employed in observing asteroids, occultations, &c., while two nights a week were set apart for the accommodation of visitors. The number of visitors at night is about 2500 per annum, the majority of whom are women. In the estimates of appropriations required for the service for the year ending June 30, 1894, we see that the superintendent asks for an expert elevator conductor, which is essential to prevent accident. Among the estimates for the new observatory is a request for three dwellings for observers, and this is accompanied by a note which we print here, and the truth of which every astronomer will endorse:—"In order that the work of a large observatory may be properly and economically done, it is absolutely necessary that the observers be within prompt call to their instruments throughout day and night. Very important observations can often be secured from the clearing of the sky for a few hours, or even in some cases for a few minutes, if the observer be within easy call by the watchman. This can only be accomplished, in the isolated situation of the new Observatory, by having dwellings upon the grounds for the observers. The Government erects dwellings at all its navy-yards, arsenals, forts, and schools for the officers on duty there. But no service requires such unremitting attention and constant presence at all hours as that of the astronomer, and no observatory can be regarded as economically managed which does not furnish dwellings for all its observers close by their instruments. It is estimated that with the observers living on the grounds of the new Observatory, not only will two or three times as much work be done as it will be possible to do otherwise, but the quality of this delicate work will be materially improved on account of the observers being in a proper physical condition to begin their labours, instead of with nerves unstrung from hurrying some miles from their homes immediately after meals, or at unreasonable hours of the night."

YALE ASTRONOMICAL OBSERVATORY.—Vol. i. Parts 3 and 4 of the publications of the Astronomical Observatory of Yale University contains (1) "A Triangulation of Stars in the Vicinity of the North Pole," by Prof. William L. Elkin; and (2) "Determination of the Orbit of the Comet 1847 VI.," by Miss Margaretta Palmer. With regard to the former paper, this was undertaken to determine the relative positions of some north polar stars to serve as fundamental points for a photographic survey of that region. Twenty-four stars, covering a considerable area, were selected for this work, and all the distances measured were large—that is, above 1000″. Out of 276 possible combinations of measuring the intermutual distances within the range of the heliometer, Prof. Elkin managed to employ 146, each combination undergoing three separate measurements. In the reduction of the measurements he gives full information as to the methods employed, showing the means of eliminating the systematic errors, &c., concluding with tables of the final results in Right Ascension and Declination and precessional tables. Miss Palmer prefaces her determination of the orbit of comet 1847 VI. with a short reference to its discovery and history, remarking that it is probably the only comet ever discovered independently by two women. Rümker in 1857 found the orbit to be of a distinctly hyperbolic nature, and the result of the present determination, by employing modern places for the sun and allowing for perturbations, &c., show that the observations can be best explained on the hypothesis of the hyperolic orbit, the new value for the elements differing slightly from the old ones.

GEOGRAPHICAL NOTES.

A COLONY only accessible through foreign territory is naturally unsatisfactory to its holders, and since the development of German South-west Africa, the inconvenience of having Walfish Bay as the only landing place for the interior has gradually increased. It is now announced that a new harbour has been found on German territory in the mouth of the Swartkop river. The stream is so small that it is marked on few general maps of Africa, and it may even turn out to be in the British sphere.

A PAPER for the next German Geographentag has been published in advance, by Prof. W. Köppen, under the title "Die Schreibung geographischer Namen." It deals in a very thorough manner with the principles which ought to regulate the orthography of place-names, and treats the whole matter of authoritatively published rules in a historical way from the first formulation of the Royal Geographical Society's Rules in 1885 to the new German rules (see NATURE, p. 89) adopted in 1892. Prof. Köppen has fully mastered his subject, and, from a thorough study of the phonetics of language, he has been able to formulate a scheme by which the Roman alphabet may be employed, with the aid of diacritical signs and groups of consonants, to represent almost every possible sound. The methods adopted in the official systems of the Royal Geographical Society and the German Colonial Office appear to the author of the pamphlet to be incomplete and unsatisfactory. The subject is one eminently adapted for full international discussion, and we hope that Prof. Köppen will not fail to bring the matter before the next international Geographical Congress.

POLAR exploration seems to have received a fresh stimulus, and we note with satisfaction the announcement in the American newspapers of Mr. Peary's new programme. He sails for Greenland in June, and will spend the winter not far from the site of his last winter's camp. A novelty in transport on the inland ice is to be the use of ponies shod with snow-shoes of a special pattern, experience in Alaska and Norway appearing to establish the practicability of the idea. The main object of the expedition is to survey the Arctic Archipelago immediately north of Greenland, and to determine the whole north coast of the mainland. Mr. Peary has no theories, and expects to have to modify his plans according to circumstances. He expects to reach higher latitudes than have previously been attained, but has no sentimental views as to reaching the pole. The whole of the expense of the expedition he hopes to defray by his lectures and the book describing his last year's experience, which will be published in June.

STROMBOLI.[1]

ON June 24, 1891, an earthquake and volcanic explosion took place, followed by another shock on June 30. Some days after, the authors spent three days at Stromboli, and subsequently studied at their homes the materials they collected.

The paper commences with a description of the island, which not only adds nothing to what has already been published, but is inferior to what has been described by others. Mention is made of many changes during the last century, but great care is taken not to mention several writers who have described and illustrated the changes during the last few years. The writer, who was the first to photograph the crater of Stromboli, and has since published new photographs, is not even referred to, yet those photos are the best so far published of the volcano. It is regretable to see the frequency with which Prof. Mercalli quotes himself to the exclusion of several of his own countrymen, and especially foreigners. Since 1887, the single crater has been replaced by a number of cones which, according to the authors, are the same as those of 1889. I myself visited the crater in 1889, and those in the plates of this paper are very different in situation, which I can confirm by photos in my possession. The matter is of little importance, but more care should be shown in such statements. Those who have a good practical experience of active volcanoes know how often, from day to day these central conettes change.

The shock of the present eruption was quite local and was unobserved at Lipari. It was much more violent on the upper part of the mountain than lower down, and the authors reasonably conclude that the explosion was limited to the actual crater. Several landslips occurred on the crumbling slopes of the island. A column of vapour and lumps of incandescent lava were ejected to a level with the summit of the island, that is for a height of 225 m. Dust and lapilli were spread over the island though not to any great amount. Lava immediately began to flow from a short rift.

On June 30, another shock occurred, sufficiently strong to disturb the Milne seismoscopes of Lipari. After the usual ejection of lava cakes, lapilli, stones, &c., another lava stream started from a point near the eastern mouths. By July 6, when the authors visited the crater, the excessive activity had so diminished that no more lapilli or dust was being ejected. Three currents of lava flowed down the Sciarra to the sea, and as one divided into two branches, four reefs were formed at the water-line which it appears are being rapidly swept away by the waves.

The microscopic and chemical examination of the lava shows it to be a basalt verging on an andesite with 50 per cent. of SiO_2, with a little more potash than soda. The scoria ejecta resemble the lava in composition, except so far as their different rate of cooling modifies them. Besides the *essential*, some *accessory* ejecta were thrown out, which were old fumarolised materials from the new crater walls. The dust, or ashes, as the authors call it, was partly composed of black vitreous particles and glass fibres mixed with a brownish powder from the trituration of older volcanic materials.

No relation was found to exist between the eruptive spasm of Stromboli with several earthquakes that occurred before and after. A list of known eruptions of Stromboli are given, but it is a most imperfect one; for example the eruption of 1768, which was actually figured by Sir William Hamilton in his masterly work, is not even referred to, although lava not only issued from the crater, but also from a lateral opening on the western side of the Stromboli, and also was the first recorded issue of lava from this volcano. This list is more complete of late years, there being no less than fourteen eruptions from 1879 to 1888. Prof. Mercalli thinks there is a sympathetic action between the outbursts of Stromboli and Etna, and also the seismic foci of South Italy. He likewise finds a faint relationship between the position of the sun and moon when in opposition and conjunction but not with barometric pressure, but says that the daily variation in activity may so be related, as stated by the inhabitants.

H. J. JOHNSTON-LAVIS.

FORTHCOMING SCIENTIFIC BOOKS.

MR. MURRAY has in preparation:—"The Life of Prof. Owen," based on his correspondence, his diaries, and those of his wife, by his grandson, the Rev. Richard Owen, with portraits and illustrations, 2 vols.; "Alone with the Hairy Ainu; or, 3,800 Miles on a Pack Saddle in Yezo and a Cruise to the Kurile Islands, by A. H. Savage Landor, with map and numerous illustrations by the author; "A Manual of Naval Architecture," for the use of officers of the navy, the mercantile marine, ship-owners, ship-builders, and yachtsmen, by W. H. White, F.R.S., third edition, thoroughly revised and in great part re-written, with 150 illustrations; "The Physiology of the Senses," by Prof. John McKendrick and Dr. Snodgrass, with illustrations (1) touch, taste, and smell (2) the sense of sight (3) sound and hearing; "Chapters in Modern Botany," by Prof. Patrick Geddes, with illustrations; "The Philosophy of the Beautiful, Pt. II.," by Prof. Knight; "Logic, Inductive and Deductive," by Prof. William Minto; "The Metallurgy of Iron and Steel," by the late Dr. John Percy, F.R.S., a new and revised edition, with the author's latest corrections, and brought down to the present time, by H. Bauerman, with illustrations.

Messrs. Longmans announce:—"Theosophy or Psychological Religion," the Gifford lectures delivered before the University of Glasgow in 1892, by Prof. F. Max Müller; "Telephone Lines and their Properties," by Prof. W. J. Hopkins; "Essays on Rural Hygiene," by Dr. George Vivian Poore; "Abdominal Hernia," by John Langton, M.R.C.S.; "A Treatise on Electricity and Magnetism," by G. W. De Tunzelmann in 2 vols.; "Papers and Notes on the Glacial Geology of Great Britain and Ireland," by the late Prof. Henry Carvill Lewis, edited from his unpublished MSS., with an introduction by Dr. Henry W. Crosskey; "The Making of the Body, a Reading Book for Children on Anatomy and Physiology," with many illustrations and examples, by Mrs. S. A. Barnett; "A Manual of Machine Drawing and Design," by David Allan Low (Whitworth scholar) and Alfred William Bevis (Whitworth scholar), with over 700 illustrations; "Diseases and Injuries of the Teeth, including Pathology and Treatment," a manual of practical dentistry for students and practitioners, by Morton Smale, M.R.C.S., and J. F. Colyer, L.R.C.P.; "Cotton Weaving and Designing," by John J. Taylor; "Clinical Lectures on Abdominal Hernia," chiefly in relation to treatment, including the radical cure, by William H. Bennett, F.R.C.S., with twelve diagrams in the text; "The Elements of Bacteriology," a manual for practitioners and students, by Prof. S. L. Schenk, translated by Dr. W. R. Dawson, with 100 illustrations, some of which are coloured; "Esquimaux Life," by Fridtjof Nansen, translated by William Archer, with illustrations.

Among Messrs. Macmillan and Co.'s announcements are:—"William Kitchen Parker, F.R.S," a short memoir by his son, Prof. T. Jeffery Parker, F.R.S.; "Text-book of Pathology: Systematic and Practical," by Prof. D. J. Hamilton, Vol. II.; "A Uniform Edition of Prof. Huxley's Essays," in 6 vols., comprising Lay Sermons, Addresses and Reviews, Critiques and Addresses, Science and Culture, American Addresses, Man's place in Nature, &c.; "Lectures on Sanitary Law," by A. Wynter Blyth, M.R.C.S.; "A Text-book of the Physiological Chemistry of the Animal Body," including an account of the chemical changes occurring in disease, by Prof. Arthur Gamgee, F.R.S., with illustrations, Vol. II.; "Tables for the Determination of the Rock-forming Minerals," compiled by Prof. F. L. Loewinson-Lessing, translated from the Russian by J. W. Gregory, with a glossary added by Prof. G. A. J. Cole; "Text-book of Geology," by Sir Archibald Geikie, F.R.S., with illustrations, third edition, thoroughly revised; "Atlas of Classical Antiquities," by Th. Schreiber, edited for English use by Prof. W. C. F. Anderson; "The Soil in Relation to Health," by Henry A. Miers and Roger Crosskey; "Elementary Treatise on Modern Pure Geometry," by R. Lachlan;

---

[1] "Sopra il periodo eruttivo dello Stromboli cominciato il 24 Guigno, 1891." By A. Ricco and G. Mercalli. Con appendice dell' Ing. S. Arcidiacono. *Ann. d. Ufficio C. Met. e Geodinamico* ser. sec., pt. iii. vol. xi. 1889. (Paper printed 1892.)

"Exercises in Euclid," by William Weeks; "Utility of Quaternions in Physics," by Alexander McAulay.

In the Clarendon Press list are:—Locke's "Essay concerning Human Understanding," edited by Dr. A. C. Fraser; "Mathematical Papers of the late Prof. Henry J. S. Smith, with portrait and memoir, two volumes; "A Supplementary Volume to Prof. Clerk Maxwell's Treatise on Electricity and Magnetism," by Prof. J. J. Thomson, F.R.S.; "A Manual of Crystallography," by Prof. M. H. N. Story-Maskelyne, F.R.S.; "Analytical Geometry," by W. J. Johnston; "A Treatise on the Kinetic Theory of Gases," by Dr. H. W. Watson, new edition; "An Elementary Treatise on Pure Geometry," with numerous examples, by J. W. Russell; "Index Kewensis Nominum Omnium, Generum et Specierum, Plantarum Phanerogamarum,' 1735–1885, Part I.; "Hospital Construction," by Sir Douglas Galton, F.R.S.

Messrs. Swan Sonnenschein and Co.'s list contains:—"Philosophy and Political Economy in their Historical Relations," by Dr. James Bonar; "Appearance and Reality," by F. H. Bradley; "The Principles of Psychology," by G. F. Stout; "History of Philosophy," by Dr. Johann Eduard Erdmann, translated and edited by Prof. Williston S. Hough, third edition, revised, three volumes; "A Student's Text-Book on Botany," by Prof. Sidney H. Vines, F.R.S., copiously illustrated; "Text-book of Embryology: Invertebrates," by Drs. Korschelt and Heider, translated and edited by Dr. E. L. Mark and Dr. W. M. Woodworth, fully illustrated; "The Cell: its Anatomy and Physiology," by Dr. Oscar Hertwig, translated and edited by Dr. H. J. Campbell, fully illustrated; "Text-Book of Palæontology for Zoological Students," by Theodore T. Groom, fully illustrated; "Lectures on Human and Animal Psychology," by Prof. Wilhelm Wundt, translated and edited by James Edwin Creighton and Edward Bradford Titchener; "Hand-book of Systematic Botany," by Prof. E. Warming, translated and edited by M. C. Potter, fully illustrated; "An Elementary Treatise on Practical Botany," by Prof. E. Strasburger, translated and edited by Prof. W. Hillhouse, with 149 illustrations, third edition; "The Photographer's Pocket Book," by Dr. E. Vogel, translated by E. C. Conrad, with 63 illustrations; "How Nature Cures," by Dr. Emmet Densmore; "Beauty and Hygiene for Women and Girls," by a Specialist; "A Popular History of Medicine," by Edward Berdoe, M.R.C.S.; "Introduction to the Study of the Amphioxus," by Dr. B. Hatschek and James Tuckey, illustrated; "Practical Bacteriology," by Dr. Migula, translated and edited by Dr. H. J. Campbell, illustrated; "Geology," by Dr. Edward B. Aveling, illustrated with a Geological Map and numerous woodcuts; "Zoology," by B. Lindsay, illustrated; "Fishes," by the Rev. H. A. Macpherson; "Flowering Plants," by James Britten; "Grasses," by W. Hutchinson; "Mammalia," by the Rev. H. A. Macpherson.

Messrs. George Philip and Son will publish:—"Philip's Atlas Guide to the Continent of Europe," a series of 72 plates, with descriptive letter-press, by J. Bartholomew; "Philip's Systematic Atlas for Higher Schools and General Use," a series of physical and political maps, with diagrams and illustrations of astronomy and physical geography, by E. H. Ravenstein; "Philip's Anatomical Model of the Human Body," illustrating the construction of the Human Frame and the relative positions of its various organs by means of superimposed plates printed in colours; "The Celestium, or Patent Astronomical Calendar for recording and illustrating in miniature the daily and hourly positions of the heavenly bodies as they pass through the Sign of the Zodiac."

Messrs. Percival and Co. give notice of:—"The School Euclid," an edition of Euclid, Books III. to VI., with notes and exercises, by Daniel Brent; The Beginner's Text Books of Science: "Chemistry," by G. Stallard; "Geology," by C. L. Barnes; "Electricity and Magnetism," by L. Cumming; "Heat," by G. Stallard; "Light," by H. P. Highton; "Mechanics" (treated experimentally), by L. Cumming; "Physical Geography," by C. L. Barnes; "Practical Physics," an introductory handbook for the physical laboratory, in three parts, by Prof. W. F. Barrett; Part II. Heat, Sound, and Light. Part III. Electricity and Magnetism, Electrical Measurements; "Practical Lessons and Exercises in Heat for use in schools and Junior University classes, by A. D. Hall.

In Messrs. A. and C. Black's announcements we notice:—"Illustrated Text-Book of Invertebrate Zoology," by A. E. Shipley; "History of Astronomy during the Nineteenth Century," by Agnes M. Clerke, third edition, revised and enlarged; "Algebra, an Elementary Text-Book for the Higher Classes of Secondary Schools and Colleges," by Prof. George Chrystal, Part I., third edition.

Messrs. Crosby Lockwood and Son have in hand:—A new and enlarged edition (the third) of Prof. R. Wallace's "Farm Live Stock of Great Britain," containing additional phototype engravings of notable specimens of live stock; and a new volume by Prof. Sheldon on "British Dairying."

Mr. Walter Scott will issue in the "Contemporary Science Series":—"Modern Meteorology," by Dr. Frank Waldo, with 112 illustrations.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—Two Radcliffe Travelling Fellowships, each of the value of £200 per annum, and tenable for three years, have been awarded this week. One, which has been gained by Mr. E. A. Minchin, of Keble College, was thrown open last year to candidates in all branches of science, and the usual declaration that the Fellow intends to graduate in medicine and to travel abroad with a view to his improvement in that study has been dispensed with. Mr. Minchin was placed in the first class in the Honour School of Natural Science (Morphology) in 1890. The other Fellow, Mr. W. Ramsden, of Keble College, is subject to the usual conditions attached to these Fellowships. Mr. Ramsden obtained a first class in Natural Science (Physiology) in 1892.

The new laboratories for the department of human anatomy are rapidly approaching completion, and will, when finished, add very much to the convenience and advantages of medical students. The buildings have been designed after the plans of Mr. Arthur Thompson, and include a large dissecting room and several additional laboratories and private rooms, a lecture theatre, and a large basement.

CAMBRIDGE.—The Council of the Senate report that the Royal Geographical Society have renewed their generous offer to provide £150 a year as part of the stipend of a geographical lecturer for the ensuing five years, and to award biennially exhibitions or prizes for the encouragement of geographical research in the University. The Council recommend that the proposals of the society be accepted, and that a lecturer be appointed, under the supervision of a joint committee of management, before the end of the Easter Term, 1893.

The Sedgwick Memorial Syndicate report that they have made certain alterations in the plans for the proposed Geological Museum in Downing Street, with a view to meeting objections that were raised and to reducing somewhat the cost of the building. The Syndicate ask to be authorised to obtain tenders for the immediate construction of the museum.

SCIENTIFIC SERIALS.

American Meteorological Journal, February.—Hot winds in Texas, May 29 and 30, 1892, by I. M. Cline. Hot winds occur to some extent every year, but rarely with sufficient intensity to injure vegetation. It was estimated that in the present case 10,000 acres of cotton were destroyed, and corn suffered severely. The temperatures reported ranged generally from 90° to 100°, and in some parts from 105° to 109°. These winds appear to have resulted from the same causes which produce the Föhn in Switzerland, the descent of dry air which has deposited its vapour during its ascent.—The electrification of the lower air during auroral displays, by A. McAdie. The author gives an account of some experiments made at Blue Hill observatory, for obtaining, by means of a kite flown during thunderstorms, a better record of the potential of the air than could be given by a collector near the ground, by which plan some remarkable results were obtained, and he suggests similar experiments for showing the electrification of the lower air during displays of aurora. He also proposes a new classification of the various auroral phenomena, distinguishing between the highly coloured displays, and those of less intensity which probably occur in the lower atmosphere.—Practical koniology, by Prof. Cleveland Abbe. He applies this term to the study of atmospheric dust and floating germs, and shows how their injurious effects on certain industries may be obviated.—The sling psychrometer, by Prof. H. A. Hazen, and the aspiration *versus* the sling psychrometer, by A. L. Rotch. Both papers deal with the comparative merits of the two instruments for balloon observations.

Wiedemann's Annalen der Physik und Chemie, No. 2.—Among the papers in this number are the following:—A modified astatic galvanometer, by H. E. J. G. du Bois and H. Rubens. To minimise the effects of disturbing vibrations as producing false oscillations about a vertical axis, the suspended system is given perfect "inertia symmetry" about the axis of the fibre, and all flat parts of it are distributed so as to have equal areas in two mutually perpendicular planes. Quartz fibres are used for suspension.—Bolometric investigations of the grating spectrum, by F. Paschen.—The fundamental law of complementary colours, by Paul Glan. To determine the amount of light absorbed by the pigment of the yellow spot during transmission to the optically sensitive nerves, two candles of equal luminosity were observed with one eye through glasses of various colours, the one direct, and the other at such an angle that its image fell outside the margin of the yellow spot. The candles were shifted till both appeared equally bright, and their respective distances were measured. Taking the coefficient of absorption for red light as = 1, that for yellow (5828) was 0·889, for wave-length 5222 it was 0·171, 4856 (blue) 0·269, and for white light 0·424. In this way the conclusion was arrived at that the intensities of complementary colours reaching the retina must be equal in order to give the impression of white.—Experiences with the self-acting mercury pump, by A. Raps. Several improvements are described, tending to make the working more rapid. It was found that the fear of contaminating the mercury by the use of black flexible india-rubber tubes was unfounded.

SOCIETIES AND ACADEMIES.

LONDON.

Entomological Society, February 22.—Mr. Henry John Elwes, President, in the chair.—Mr. F. J. Hanbury exhibited, on behalf of Mr. Percy H. Russ, of Sligo, several long and very variable series of *Agrotis tritici*, *A. valligera*, and *A. cursoria*, together with Irish forms of many other species, some of which we believe to be new to Ireland. Mr. W. H. B. Fletcher made some remarks on the species.—Mr. R. W. Lloyd exhibited specimens of a species of *Acarus* found in New Zealand wheat. He stated that Mr. A. D. Michael had examined the specimens, and pronounced them to belong to *Tyroglyphus farinæ*, a species which had been known for over a hundred years as a destroyer of corn, and was only too abundant all over Europe, and probably over the temperate regions of the world.—Mr. E. B. Poulton, F.R.S., exhibited, and made remarks on, a number of cocoons of *Halias prasinana*, in order to show the changes of colour produced in them by their surroundings; he also exhibited the coloured backgrounds employed by him in his recent experiments on the colours of larvæ and pupæ, and illustrated his remarks by numerous drawings on the blackboard.—Dr. T. A. Chapman exhibited by means of the oxy-hydrogen lantern, photographs of the larva of *Nemeobius lucina* in its first stage, showing the conjoined dorsal tubercles, each carrying two hairs, which are remarkable in being divided into two branches. For comparison he also showed, by means of the lantern, drawings of the young larva of *Papilio ajax*, after Scudder, and of a portion of a segment of *Smerinthus populi*, as the only instances known to him of similar dichotomous hair sin lepidopterous larvæ. Mr. Poulton pointed out that he had described the forked hairs of *Smerinthus* in the Society's "Transactions" for 1885, and that such hairs were even better developed in the genus *Hemaris* originally described, as he believed, by Curtis. Mr. Poulton, also said that he had noticed similar forked hairs covering the newly-hatched larvæ of *Geometra papilionaria*.—Dr. Chapman read a paper—which was illustrated by the oxy-hydrogen lantern—entitled "On some neglected points in the structure of the Pupa of Heterocerous Lepidoptera and their probable value in classification." A discussion ensued, in which Mr. Poulton, Mr. Champion, and Mr. Merrifield took part.—Dr. F. A. Dixey communicated a paper entitled "On the phylogenetic significance of the variations produced by differences of temperature on *Vanessa atalanta*." The President, Mr. Merrifield, Mr. Poulton, Dr. Chapman, and Mr. Tutt took part in the discussion which ensued.

Zoological Society, February 28.—Sir W. H. Flower, F.R.S., President, in the chair.—Mr. A. D. Michael exhibited some specimens of the *Ixodes*, known locally in the West Indies as the "St. Kitts" or "Gold Tick," received from Mr. C. A. Barber, of the Agricultural Department, Antigua.—A communication was read from M. A. Milne-Edwards respecting *Lemur nigerrimus*, Sclater, a species of lemur originally described from an example living in the Society's Gardens. It was pointed out that *Prosimia rufipes* of Gray had been based on a female of this species.—Mr. Howard Saunders exhibited and made remarks on a specimen of the American stint (*Tringa minutilla*), shot at Northam Burrows, North Devon, by Mr. Broughton Hawley, in August, 1892.—Mr. Sclater (on behalf of Mr. R. M. Barrington) exhibited a specimen of the Antarctic Sheathbill (*Chionis alba*), killed at the Carlingford Lighthouse, co. Down, Ireland, in December last.—Dr. C. J. Forsyth-Major read a memoir on some of the miocene squirrels, and added remarks on the dentition and classification of the *Sciuridæ* in general. The author proposed a new division of this family into three subfamilies—Sciurinæ, Pteromyinæ, and Nannosciurinæ. The genera *Spermophilus* and *Arctomys* and the allied forms were united to the Sciurinæ. The last part of the paper dealt with the primitive type of the Sciurine molar.—Mr. Henry O. Forbes read a paper entitled "Observations on the Development of the Rostrum in the Cetacean Genus *Mesoplodon*. with remarks on some of the Species." Mr. Forbes showed that in this genus the vomerine canal in the young animal is filled with cartilage, and in the adult with a dense petrosal mesorostral bone. From the examination of thirteen specimens of *Mesoplodon grayi* and four of *M. layardi*, of which he had made a large number of sections in various stages of growth, the author concluded that the mesorostral bone was not, as had been generally believed, an ossification of the cartilage, but an actual growth of the vomer and of the premaxillaries, with perhaps, in some cases, additions from the ossification of the cartilage of the vomerine spout. The cause of the growth in the vomer might be accounted for by the pressure communicated to it by the growth of the premaxillaries, induced, perhaps, by the movement, which appears to take place, of the maxillaries over the premaxillaries.

Linnean Society, March 2.—Prof. Stewart, President, in the chair.—Mr. Miller Christy exhibited some photographs of the American bison taken from living wild animals, and gave some account of the present restricted distribution of the species. Mr. A. G. Renshaw and Mr. W. Carruthers detailed what they had been able to learn respecting it while travelling in its former haunts.—Mr. J. M. Macoun gave an account of the flora of the Behring's Sea Islands from personal exploration.—On behalf of Mr. H. N. Ridley the Secretary read a paper on the flora of the eastern coast of the Malay archipelago.—The meeting then adjourned to March 16.

Anthropological Institute, February 21.—Prof. A. Macalister, F.R.S., President, in the chair.—A paper, by Mr. E. H. Man, on Nicobar pottery was read. He stated that the little island of Chowra has held for generations a monopoly of the manufacture. Preparing the clay, and moulding and firing the finished utensil, devolves on the females. The value of trade marks is recognised, the device of its maker being affixed to each vessel. Experience having taught them that pots are more serviceable if allowed to harden gradually, they store newly-made utensils on a lattice platform in the roofs of their huts. In a year the heat and smoke render them hard and durable. Indian pots and jars are readily purchased from the traders, who occasionally visit the islands; but they are deemed unsuitable for certain culinary operations. There are no special vessels made for funeral purposes; but, in accordance with the almost universal custom of uncivilised races, cooking pots are among the personal and household requisites which are laid on a grave after an interment.—A paper, by Lieut. Boyle, T. Somerville, R.N., on some islands of the New Hebrides was read. The habits of the natives of adjacent islands sometimes vary exceedingly, and in this paper reference was made only to a small portion of the group, including the Efate Islands, the Shepherd Islands, and the East Coast of Malekula. A child calls all his uncles on both sides, "father," all his aunts, "mother," and his first cousins on both sides, "sister" or "brother." A man cannot marry a woman of his own tribe, and the children belong to their mother's tribe; the property of their father going, at his death, to his sister's children. It sometimes happens that a man will call a small girl much younger than himself "mother." Circumcision takes place between the ages of five and ten. Till then a boy goes naked; but afterwards he is costumed like the men. When a Malekulan is old and decrepit, he has nothing to look forward to but burial alive. Should an old person become bedridden, or a burden, he or she is told quite simply that his or her burial will occur on such a day. Invitations to the funeral feast are then sent out, and, dead or not dead, on that date the unhappy person is buried.

Paris.

Academy of Sciences, February 27.—M. de Lacaze-Duthiers in the chair.—On the attempt at oyster culture in the Roscoff laboratory, by M. de Lacaze-Duthiers. In April, 1890, a set of seed oysters were introduced into a tank in the grounds of the observatory, which lies opposite Batz Island, in the Channel. They were always submerged, but exposed to tidal changes of level. In a year they had acquired a considerable size, but had not yet "fattened." Last November they had a size and flavour which, in M. Chatin's opinion, surpassed the qualities attained in any other locality along the coast, although in the warmer months preceding (the months without R) they had shared the decline common to all oysters at that period. It was also found that the oysters in the tank acquired longer "beards," and also increased in length, whilst others cultivated on the shores of Batz Island, and often left dry at low water, were more developed in the direction of thickness. As regards reproduction, the results have been fairly favourable, although definite data have not yet been obtained. In one case, where part of the tank water had been pumped into a reservoir used for supplying an aquarium, some embryos were drawn up through the pipes, and fixed themselves on the wooden level-ball, where a colony of about a dozen well-developed oysters was subsequently found, some of which now measure 6 cm. across.—On the exact determination of the pepto-saccharifiant action of the organs, by MM. R. Lépine and Metroz.—On the photographs of the moon enlarged by Prof. Weinek, by M. Faye. These photographs are enlargements by twenty times of some of the Lick photographs of the moon, obtained by an exposure lasting several days. On their being exhibited, several members expressed their opinion that they had been retouched.—On the urea contained in the blood in cases of eclampsia, by M. L. Butte. It is found that in cases terminating fatally the amount of urea contained in the blood is less than in cases of recovery, owing to hepatic alterations, which in the former cases impair the secretion of urea. From the point of view of prognostication, therefore, recovery can be anticipated if the amount of urea is two or two and a half times the normal amount, but a fatal issue if the amount closely approximates to the physiological figure.—On the general problem of integration, by M. Riquier.—On certain differential equations of the first order, by M. Vessiot. — Remarks concerning a preceding note on a generalisation of Lagrange's series, by M. E. Amigues. — Physical properties of fused ruthenium, by M. A. Joly (see Notes).—On Stas's determination of the atomic weight of lead, by M. G. Hinrichs. In Stas's determinations of the atomic weight from the sulphate and the nitrate the weight of substance taken, according to M. Hinrichs, enters as a continuously changing element into the result, owing to a systematic error in Stas's arrangement. In plotting the atomic weights in terms of weight of substance taken, curves are obtained showing a minimum at about 150 gr. The method of averages is therefore inadmissible, and a new method is promised in a forthcoming communication.—On the aldehydes of the terpenes, by M. A. Étard.—On the constitution of hydrated alkaline phenates, by M. de Forcrand.—On the alkaloids of cod-liver oil, their origin and therapeutic effects, by M. J. Bouillot.—On a pathogenic microbe of blennorhagic orchitis, by MM. L. Hugounenq and J. Eraud.—Crustacea and cirrhipeds commensal with the Mediterranean turtles, by MM. E. Chevreux and J. de Guerne.—On a terrestrial leech of Chili, by M. Raphael Blanchard. This animal, which has been named *Mesobdella brevis*, forms a link between the Glossiphonidæ and the Hirudinidæ. Among the latter it approaches most closely the Hemadipsinæ by its mode of living and its ten large black eyes, but differs from the whole family by the great condensation of its somites.—Mineralogical and lithological examination of the meteorite of Kiowa county, Kansas, by M. Stanislas Meunier. The metallic portion presents two principal alloys of iron and nickel, which an attentive study has succeeded in characterising: Tænite (Fe_6Ni) and plessite ($Fe_{10}Ni$). In composition it agrees closely with the entirely metallic type called jewellite, but it differs from the latter in structure. Apart from the peridotic portions the mass consists of lamellæ of tænite arranged in bundles which frequently intersect at the angles of the octahedron. The intervals are filled up with plessite which may be distinguished at once by its dark-grey colour, contrasting with the polished steel tint of the other alloy. Some specimens of the meteorite show quite exceptional characters. With the usual structure and cohesion they are formed of opaque black mineral grains cemented by a network of oxidised iron. These have probably been produced by an alteration of the normal specimens, in which the metallic skeleton has been oxidised.

Göttingen.

Royal Society of Sciences.—From July 27 to December 28, 1892, the following papers of scientific interest have appeared in the *Nachrichten*:—

July.—Drude: Current theories of light practically tested.—Ehlers: On *Arenicola marina*, L. (five pages).—Rhumbler: The so-called germ-spherules (Max Schultze) of *Foraminifera* (these are stated to be merely deposits of iron silicates).—Nernst: The change of free energy in the mixture of concentrated solutions.—Hilbert: Third note on algebraical invariants.

September.—Fricke: A general arithmetical principle in the theory of automorphic functions.—Kohlrausch: On the influence of time upon solutions of sodium silicates.

November.—Peter: Botanical work in the summer of 1892.—Voigt: On a problem in fluid motion.—Sella and Voigt: The rupture coefficient of rock salt.—Kallius: The neuroglia-cells of peripheral nerves.

December.—Wagner: The third (Peter Apian's) map of the world (1530).

MACPHERSON'S FAUNA OF LAKELAND.

A Vertebrate Fauna of Lakeland, including Cumberland and Westmoreland, with Lancashire North of the Sands. By the Rev. H. A. Macpherson, M.A., with a Preface by R. S. Ferguson, F.S.A. (Edinburgh: D. Douglas, 1892.)

INTRODUCED to the vocabulary of naturalists by Mr. H. Cottrell Watson, more than fifty years ago, and that in the most prosaic way, the word "Lakes," as the name of an English district, still keeps its poetic fragrance, which is perhaps even intensified by its modern modification into "Lakeland," notwithstanding the very technical prefix, as in the title of this book, of "A Vertebrate Fauna." One is naturally led to think of that school of versifiers whose early efforts excited so many conflicting feelings when the century was young, but whose later lays have at length brought conviction of their worthiness to the minds of most. One of their company, he who furnishes the motto of this journal, has especially been hailed as *the* Poet of Nature, and not only does the fame of Wordsworth wax yearly, but there are those who greet every line he wrote with adulation. To such admirers the author of the book before us will seem to have missed his opportunity, in that we fail to find in the whole volume any indication of the penultimate Poet Laureate having ever belonged to the "Vertebrate Fauna of Lakeland." Does this signify that naturalists are not poetical or that the great "Poet of Nature" was not a naturalist? The question is so momentous that we leave it for consideration by our readers, not daring to vouchsafe a reply, nor venturing to suggest to Mr. Macpherson that he has been wrong in resisting the temptation to illustrate his work by quotations, that might be gathered by the handful from the thousands of verses which flowed from the pen of the "bard of Rydal," or any of his brethren.

We must acknowledge that we took up this volume with a slight prepossession against it. We did not see why Mr. Macpherson, already the joint author of a well-known and well-esteemed little book on the "Birds of Cumberland," to say nothing of various contributions to Natural History journals, should need a preface for his new work by a gentleman who—whatever may be his legal and antiquarian renown (which we believe to be not small)—is entirely unknown as a naturalist, and it seemed to us as though a kind of sub-episcopal *imprimatur*, which would be derogatory to a man of science, had been sought from the Chancellor of the diocese of Carlisle. We have been glad to find this suspicion, perhaps ill-natured in its inception, wholly unfounded as we became acquainted with the contents, and we hereby make confession of our error, duly cautioning all others, and there may be a good many of them to whom the same thought may occur or have occurred, that any such hesitation is unnecessary. The Preface, it is true, contains a benediction, but none can say it is a benediction that is undeserved. The book is a real honest book, and one that no true zoologist can fail to discover has been wrought at with conscientious care, unbounded labour, and a deep sympathy with the subject. We are not going to hold it up as a model "Fauna"; there is evidence, notwithstanding what we have just said, of too much haste in its composition for that; but it certainly belongs to the first class of books of its kind, while, should it be the author's good fortune to have another edition demanded, a severe revision might give it a high place in that class. We do not assume ourselves to be purists in style, but it does seem to us that the English language, as written by men of acknowledged literary merit, is wide enough to cover every shade of meaning, without the least necessity of bringing in words or phrases that border upon slang, and certainly without using slipshod expressions that, if not altogether inappropriate, are in many cases vague and therefore unseemly in a book that may fairly claim to rank among scientific works. We assure the author in all good will that these shortcomings, which might be so easily remedied, greatly diminish the pleasure we derive from reading his volume.

Apart from Mr. Ferguson's scholarly Preface, the book opens with more than one hundred pages of Prolegomena, and we are mistaken if the greater part of these will not prove to have greater interest for that incomprehensible person the General Reader than all that follow—the particulars given in the bulk of the volume being mostly of especial and local value. Not that we use this last epithet in any invidious sense, for what should a local Fauna be but local? and Mr. Macpherson has avoided a great error (into which the authors of some modern local Faunas have fallen), by rightly taking it for granted that the zoological readers who will use his book do not want to be instructed on points or matters concerning which they can obtain full information from many other and more original sources, and thus he is able to husband his space for particular details, which are given in most cases with great precision. But first of these Prolegomena aforesaid—They begin, as every book of this sort ought, with what is practically a history of the subject; for it is a biographical notice of former Lakelandish worthies who have contributed to the Vertebrate Zoology of their district, and of these there is a good show; though there is no wonder that the earliest writers on the subject should possess but little scientific knowledge. It is not every county that can produce a Willughby, a Sir Thomas Browne, or still less a John Ray—but probably the earliest of the naturalists celebrated by Mr. Macpherson were the equals of Charleton, Plot, or Leigh—all men worthy to be praised in their own line. Yet setting aside these lesser lights, many of whom are lost to view in the glare that radiates from their successors, the two Heyshams (John, born 1753, died 1834, and Thomas Coulthard, born 1791, died 1857), and the two Goughs (John and Thomas, whose joint lives cover all but a century and a quarter, 1757–1880)—in each case father and son—were men deserving commemoration in any county, and the biographical notice of all four, written in excellent taste, will be gladly read by many who are not naturalists at all. For our own part we cannot help wishing that these biographical details had been longer; but the papers of the elder Heysham are not forthcoming, neither is the manuscript Cumberland Ornithology, which the younger is supposed to have left at his death. The former, if still existing, would no doubt throw much light on more than fifty years of Cumbrian Natural History; but most likely everything of value in the latter was communicated to Bell or Yarrell, with whom its author was in frequent correspondence, and during his later years he led a life of seclusion. The elder Gough was an extraordinary instance of a naturalist successfully pursuing his vocation under a grave difficulty, for the like of which we can only call to mind Huber and M. Van Wickevoort-Crommelin, since at an early age he became blind from small-pox, and if he was thereby disabled from advancing investigation according to his bent, it did not hinder him from training his son to follow his footsteps and indoctrinating him with so wide an attachment to science that he became an intimate friend and correspondent of Sedgwick the geologist and of Cornelius Nicholson the antiquary, establishing with the latter's aid the Kendal Literary and Scientific Institution. The pious duty of celebrating his predecessors' obsequies being performed, Mr. Macpherson next turns to other extinct mammals of Lakeland, and his researches respecting the Wolf (an entire skeleton of which, found in a cave by Mr. John Beecham, is preserved in the museum at Kendal) and the Wild Boar have been rewarded by the discovery of documentary evidence not without interest, even if it does not add much that is of value to our information concerning these ancient beasts. We have too some facts in relation to the Red Deer and the Wild Ox, though more is said of them, and some of it is of importance, in the body of the work (pp. 50–76), and we do not see why the former at least of them should be called extinct, seeing that though greatly restricted in range it still exists in freedom, while the latter, whose right German name Mr. Macpherson persistently curtails, misspelling it "Auroch" for *Aurochs*, was undoubtedly the ancestor of the white breed, of which the last herd in the district, having been emparked at Thornthwaite near Haweswater, was removed in or soon after 1630 to Naworth, and by 1675 had ceased to exist. A chapter devoted to "The Destruction of Wild Animals" will be instructive reading to many people. It contains what will be a revelation to those who can appreciate the facts of "how not to do it." Our excellent forefathers (and many of their descendants are not much wiser) knew very little of the way in which wild beasts could be extirpated, and consequently the warfare against them lasted for centuries. Some few, still accounted enemies of the human race, yet defy their persecutors; but the greater number have perished, and in the present depleted state of the Mammalian Fauna of the British Islands, it would be inexpedient to point out how the extinction, at least in parts, of some two or three species might be accomplished in perhaps twice as many years. The average gamekeeper (fortunately or not) has very little knowledge of zoology, and the average master even less. On this particular we have no wish to enlighten either, so we shall preserve a silence that all animals' friends will admit to be golden. But we must always remember that by far the most destructive four-footed "vermin" of our day is religiously and rigorously preserved by a general sentiment, so much stronger than any law, in a way that would have caused to wonder those who "kenned John Peel" and his forefathers. In favour of Mr Macpherson's next treatise on the Variation of colour in Animals not much is to be said, and this *capitulum* will disappoint most who consult it, while we take leave to observe that though many authorities are cited from the *Carlisle Patriot* of these times to Dr. Caius of 1570, that learned man assuredly never wrote a book with a title so tautological as "*De rariorum animalium et avium stirpibus*," which must have been taken (p. lxxvi, note) at second hand from one of the popular writers, who imagine that birds are not animals and do not know the technical meaning of *stirpes*. Albinescent specimens if not albinos have, it is well known, a great charm for some collectors—why, scarcely any reasonable being can say—and it is of them that our author chiefly discourses (using too a word—"leucotism"—quite unfamiliar, but apparently meaning the same as the recognised "albinism") though so far as we know little scientific interest attaches to them; but we do not quite see the point of his remarks (p. lxxviii) on "the tendency in the direction of variation" of the Lakeland Viper. He only mentions two examples, and what are they among so many? Nevertheless the one figured is strange-looking enough, and it would have been satisfactory to be assured that there can be no mistake in the determination of the species. The succeeding chapter is devoted to Hybrid Birds; but here again we find not much of interest in a general way on that little-known and extremely interesting, not to say important, subject. Mr. Macpherson has been so fortunate as to see more than one wild hybrid between the two British species of Sparrow (*Passer domesticus* and *P. montanus*) and considering that these are species in what some would call the "physiological" sense—the sexes being outwardly alike in the latter and wholly different in the former—the question deserved further attention than is bestowed upon it (pp. lxxx—lxxxi).

More instructive is what follows on "Bird Fowling" (as the author redundantly terms it) or rather we should say more instructive it might be. There is mention (p. lxxxviii) of the netting of Razorbills and Guillemots on the rocks of St. Bees', taken, we are told, from the "Sandford MS. p. 18," but where this manuscript is to be seen or of what age it may be we are not told, and the language of the passage quoted only shows that it is not exactly of yesterday. Now the netting of *Alcidæ* is not, so far as we are aware, known to have been practised elsewhere in Britain, and Mr. Macpherson says the custom is obsolete in Cumberland, probably from there not being birds enough left to make its continuance worth the while of the "Hivites," for it may be accepted as a universal rule that the taking of birds at their breeding haunts year after year, unless under such conditions as St. Kilda presents, must end in their diminution and may easily be carried on to their extinction.

For the rest of the Prolegomena there is no need to say anything, and we willingly pass over the useless representation (p. xcvi) of the Polish Swan's trachea, though we congratulate Mr. Macpherson on being able to figure (p. ciii) the foot of a real Westmorland Sea-Eagle, not a mere "marauder from over the border"—as most of the examples killed in England are—but a mournful relic for all that.

Into the details of Lakeland species we shall not attempt to enter. To criticise that portion of the volume the critic should have nearly as much local knowledge as the author, and we pretend to none. To some though not to a great extent the besetting sin of nearly all "Faunists" is evident, and that is the tendency to exalt the importance of the capture of stray individuals, this especially among birds. The occurrence of these wanderers is undoubtedly worth recording; but that a zoologist should claim consideration for Cumberland because a *Saxicola isabellina* was shot there, or for Furness because a *Pelagodroma marina* was washed up on Walney, is an indication that he takes rather a narrow view of things—though we are bound to admit that Mr. Macpherson at the same time descants on the merits of the Wheatear as a characteristic Lakeland bird; and, especially as befits one by descent "servile to *Skyey* influences", laments the almost complete absence from the Lakeland seas of the Manx Puffin, due no doubt to its extirpation in the neighbouring island, or its Calf, that gives it an English epithet nowadays inappropriate. Indeed there is no fault to find with our author in his sympathy for the *true* denizens of his district, and the highest praise is due to him for the labour he has exercised, of which almost every page bears witness, in telling their story. To wind up we must add, what perhaps we ought to have said before, that for the purpose of this work "Lakeland" consists of the counties of Cumberland and Westmorland, together with that part of Lancashire known as Lancashire Over-Sands, being identical, the Isle of Man excepted, with the "twelfth Province" of Mr. Watson's *Cybele Britannica*; but the want of a map of the entire district is a grievous drawback, for which even the dozen or more excellent etchings, showing as many places of interest, do not wholly make amends.

THE EVOLUTION OF DOUBLE STARS.

Die Entwickelung der Doppelstern-Systeme. Von T. J. J. See. 60 pp. (Berlin: R. Friedländer und Sohn, 1893.)

THE essay which we review is a dissertation for the doctorate of philosophy of Berlin, and the author, Mr. See, is an American, although he writes in German.

The component stars in double systems appear to be usually of comparable magnitudes, and are found to move in highly eccentric orbits. This case the author holds to be the normal one, whilst the solar system, with its one preponderant mass, and its nearly circular orbits, would be exceptional.

He attributes the observed high eccentricity of orbit to the influence of tidal friction, and accordingly the greater part of the paper is devoted to the consideration of the results which will ensue from the supposition that each of two bodies raises in the other tidal disturbances, which are subject to frictional resistance.

If the rotations of the two bodies differ in speed, the problem is an insoluble one, without some postulate as to the law of the frictional resistance. The author is, however, of opinion that sufficient insight may be gained from the solution in the case where two equal bodies rotate with equal speed. This opinion seems justifiable, but it might have been well if the dynamical stability of equality of rotations had been explicitly pointed out. That there is such stability is clear from the consideration that, if one of the bodies rotates more rapidly than the other, it is subjected to a more rapid retardation of rotation, and there is accordingly a tendency towards the restoration of equality.

The influence of tidal friction on the elements of the orbit of a satellite and on the rotation and obliquity of a planet have been investigated in my several papers, and Mr. See here adapts my conclusions to the case of the double tidal friction of two stars. The adaptation is not difficult, for whilst the rate of change in the rotation of each star remains the same as though the other did not rotate, the rates of change of the elements of the orbit are exactly doubled. Mr. See has then redrawn the curves which exhibit the gradual transformation of the system, and, as might have been expected, finds them to have features closely similar to those of my curves.

The generality of these solutions is limited by the supposed smallness of the eccentricity and of the inclinations of the orbit and of the two equators to the plane of reference. The author, however, then passes to a second case, which is more special in that the equators of the stars remain coincident with the plane of the orbit, but which is more general in that the eccentricity is not treated as being necessarily small. The object is to obtain a numerical solution of the following problem:—Two equal stars, each of three times the sun's mass, revolve in a nearly circular orbit at a distance equal to that of Neptune from the sun, and the rotation of each star is nearly equal to its orbital motion; it is required to find the greatest mean distance and the greatest eccentricity of orbit to which the system will change under the influence of tidal friction.

Mr. See solves this problem by methods analogous to those which I have employed, and finds that the mean distance will increase from 30 (Neptune's distance) to 50, and that the eccentricity will increase from an assumed initial value of one-tenth to a maximum of about three-fifths, which is attained a little earlier than the maximum of mean distance.

It may be remarked that these results can only be very rough approximations to the truth, because the calculation is conducted on the supposition that the moment of inertia of each star is the same as that of a homogeneous sphere of the same mass and radius, whereas it is obvious that the stars would really be highly condensed spheroids of great oblateness.

It is to be regretted that the calculation has not been repeated with variations of the assumed initial conditions. It is easy to see that a change in the assumed degree of concentration of the stars would give very different results. Supposing, for example, the stars had had only half the diameter assumed, the rotational moment of momentum would have had a quarter of its value in Mr. See's example. Now the enlargement of orbit is due to the transference of rotational to orbital moment of momentum, and thus the transferable moment of momentum would only have amounted to one quarter of its former value. But the orbital moment of momentum varies as the square root of the mean distance, and hence the enlargement of the orbit could not have been so much as one-sixteenth of its former value. We may feel sure that the increase in the eccentricity of orbit would also have been largely reduced.

Notwithstanding this criticism, it appears to me that Mr. See fairly establishes the proposition that a high eccentricity is explicable by means of tidal friction.

Turning, then, to the question of the relative masses of the components of double star systems, Mr. See remarks with justice that the comparable brightness of the components renders it highly probable that the masses are also comparable, and he sees in certain results of M. Poincaré and of my own an evolutionary explanation of this fact.

Jacobi first showed than an ellipsoid of homogeneous fluid, with its three axes bearing to one another proper proportions, is a figure of equilibrium when it rotates about its smallest axis with a proper angular velocity. M. Poincaré next showed that if the length of the Jacobian ellipsoid exceeds the breadth in a certain ratio, the equilibrium becomes unstable, but that there is a stable figure which may be described as a Jacobian ellipsoid with a furrow nearly round the middle, so that it resembles an hour-glass with unequal bulbs. If we trace the further development of the hour-glass we find its neck gradually thinning, and finally rupturing the figure of equilibrium, henceforth consists of two detached masses.

My own attack on this problem was from the opposite point of view, for I endeavoured to trace the coalescence of a pair of detached masses so as to form an hour-glass or dumb-bell.

Mr. See reproduces the figures illustrative of both these investigations, and remarks that they both show that when there is a gradual detachment from a rotating figure of equilibrium, the detached portion will not normally be a ring, but that there will ensue two quasi-spheroidal masses of matter of comparable magnitude. He also remarks that if the fluid be heterogeneous, the ratio of the masses will be much smaller than when it is homogeneous.

In the discussion of these figures of equilibrium the wording of the essay appears a little careless, for it might naturally be supposed to mean that increase of angular velocity is a necessary concomitant of the rupture of the neck of the hour-glass. Now it is a somewhat paradoxical fact that, with constant density, the longer elongated figures of equilibrium rotate more slowly than the shorter ones, and it might therefore seem that the rupture of the neck should go with retardation of angular velocity. But it is the value of the square of the angular velocity divided by the density which determines the length of the elongated figures, and thus increase of density tells in the same way as retardation of angular velocity. In the history of a nebula the only condition for rupture which can be specified is that of contraction.

The probability of this view of the genesis of double stars is strikingly illustrated by a number of drawings by Sir John Herschel of various nebulæ. The great similarity between Herschel's nebulæ and the theoretical hour-glass is obvious. It may be hoped that in the book which Mr. See promises he will also illustrate this point by photographs.

Annulation is usually accepted as the mode of separation in the nebular hypothesis, but, as already stated, this is held by Mr. See to be exceptional. He thus regards the ring of Saturn as being as exceptional in its history as it now is in appearance. Where he maintains that Saturn's ring will never coalesce into a satellite, he might with advantage have referred to the remarkable investigations of M. Roche,[1] who showed that a satellite would be torn to pieces by tidal action if it revolved at a distance of less than 2·44 times the planet's radius. We may here note the interesting fact that whilst Saturn's ring almost touches "Roche's limit" on the inside, the Martian satellite, Phobus, and the fifth satellite of Jupiter[2] almost touch it on the outside.[3]

In order to prove his thesis as to the highness of the eccentricity and the comparability of masses, Mr. See gives a careful table of the observed elements of the orbits and of the relative brightnesses of seventy-three pairs of double stars. The values of the elements are of course open to much uncertainty, but the mean eccentricity, which is found to be ·45, must lie near the truth. In the few cases in which the masses have been determined, they are found to be comparable, and the comparability of the brightnesses confirms the generality of this law. Thus the facts of observation agree with our author's ideas.

Mr. See must be congratulated on having written an essay of great cosmogonical interest, and although his theory may never be susceptible of exact proof, yet there is sufficient probability of his correctness to inspire us with fresh interest in the observations of double stars.

G. H. Darwin.

MAGNETIC INDUCTION IN IRON AND OTHER METALS.

Magnetic Induction in Iron and other Metals. By J. A. Ewing, F.R.S. (London: *Electrician* Office.)

In this admirable book Prof. Ewing has brought together matter which was before to be found only in the journals of learned societies, and he has also given a full account of his own researches in magnetism. The book is written in a lucid style, and is supplied with numerous references to original papers.

In Chapter I. Prof. Ewing explains clearly the meaning of such terms as "intensity of magnetisation" and the like, which many students have difficulty in understanding. As stated in the preface, he has "endeavoured to familiarise the student with the notion of intensity of magnetisation (I) as well as with the notion of magnetic induction (B)." When endless magnetic circuits are discussed, it is convenient to talk of "permeability" and "induction"; on the other hand, "magnetic poles" and "magnetisation" are just as important when permanent magnets are dealt with. The magnetisation of ellipsoids and the influence of the shape and dimensions of magnetised bodies upon magnetic quality are fully treated.

---

[1] "Acad. des Sciences de Montpelier," vol. i. (1847-50), p. 243. See also Darwin, *Harper's Magazine*, June, 1889.

[2] The values given by Barnard (Nature, p. 377) make the distance 112,000 miles, and Roche's limit 107,000 miles.

[3] It is proper to warn the reader that Roche's limit depends to some extent on the density of the planet. For the sun it will be about one-tenth of the earth's distance from the sun. Thus a body of planetary size cannot move in a highly eccentric orbit, so that its perihelion distance is one-tenth, without being broken up into meteorites; and conversely a flight of meteorites with less than the same perihilion distance can never coalesce into a planet.

Chapters II. and III. are devoted to measurements of magnetic quality by the magnetometer and ballistic methods. With respect to the former very full information is given as to the construction of the apparatus and its use.

The earth's coil as a means for calibrating the Ballistic Galvanometer is fully explained, as also that of a solenoid and current. Mention is not made of a convenient method of calibration in which the quantity of electricity passed is given directly by $Q = \frac{A}{a} \frac{\tau}{2\pi}$; where A is the deflection corrected for decrement; a is the steady deflection due to unit current, and τ is the periodic time of the ballistic needle. Here a and τ are quantities very readily obtained.

The chapter concludes with a full description of Dr. Hopkinson's "Bar and Yoke" method.

Chapter IV. contains valuable information with regard to curves of induction and hysteresis in the case of wrought iron, steel, and cast iron, which will be of use to the electrical engineer in the design of dynamo electric machinery. The effects of annealing and stretching iron are brought forward and well illustrated.

The next chapter, on magnetic hysteresis, is perhaps the most important in the book. It commences by giving a clear definition of hysteresis, the effects of which are amply illustrated by curves, and stress is laid upon the definition of permeability as being the ratio of B to H *with certain limitations*.

The dissipation of energy through magnetic hysteresis—which plays such an important part in the design of cores for transformers, and the armatures of dynamos—is fully treated.

The remarks on magnetic viscosity towards the end of the chapter are worthy of very careful consideration. The author points out that in the case of quick cycles, $\int H dI$ may be widely different from what is found to be the case by static methods, and further remarks that experimental evidence is wanting under this head.[1]

Chapter VI. treats of magnetism in weak fields. The author refers to experiments by Lord Rayleigh and himself, in which the time effect upon magnetism is clearly shown—the creeping up of the magnetism going on for a considerable time.

Magnetism in strong fields is discussed in Chapter VII. The "Isthmus Method" introduced by the author and Mr. W. Low in 1887 is capable of producing magnetic fields of enormous strength. In giving his conclusions from experiments by the isthmus method the author states, "there is apparently no limit to the value to which the induction may be raised. But, when we measure magnetisation by the intensity of magnetism I, we are confronted with a definite limit—a true saturation value, which is reached or closely approached by the application of a comparatively moderate magnetic force."

A full account of Dr. Hopkinson's researches on the effect of temperature on magnetism is given in Chapter VIII., and reference is made to the identification of recalescence with recovery of the magnetic state. In the latter part of the chapter hysteresis, in the relation of magnetic susceptibility to temperature, is dealt with; and mention is made of the wide range of temperature through which the alloys of iron and nickel may exist in either the magnetic or non-magnetic state.

Reference is made to the researches on recalescence of Osmond, who has since shown the marked influence of the initial temperature, and the rate of cooling on recalescence in the case of chromium steel. Dr. Bottomley has shown that the alloys of chromium and steel in the unannealed state have exceptionally high magnetic qualities, which are confirmed by experiments of Dr. Hopkinson.

In Chapter X. the magnetic circuit is discussed, and the way in which it is applied to the design of dynamo electric machines and transformers. Reference is made to the important work of Drs. J. and E. Hopkinson and Kapp upon this subject—more especially in connection with dynamo electric machinery. In pursuing the analogy of the magnetic circuit to the ordinary conduction equation, Prof. Ewing lays stress upon the fact that the permeability (μ) is a function of the induction (B), and this is a point which cannot be too strongly urged. Much that is in this chapter has great practical importance—the treatment of the subject being considered from a graphical, as well as analytical, point of view. The chapter ends with an account of the influence upon magnetism by cuttings and the compression of joints in magnetic circuits.

The last chapter gives a complete account of the different theories of magnetism. Weber's theory is discussed with modifications by Maxwell and Wiedemann, to which are added Prof. Ewing's own views of the subject. He goes on to show that the reduction of hysteresis by vibration is explained by the molecular theory of magnetism,—and further supposes that time-lag in magnetism can be accounted for by it. The book ends with an account of Ampère's hypothesis of magnetic molecules.

E. WILSON.

OUR BOOK SHELF.

Forschungsberichte aus der Biologischen Station zu Plön. Theil I. Faunistische und biologische Beobachtungen am Gr. Plöner See. Von Dr. Otto Zacharias, Direktor der Biologischen Station. (Berlin: R. Friedländer und Sohn, 1893.)

THE first report of investigations from the biological station of Plön, in Holstein, has just been issued. It is a journal of 52 pages with one plate, bearing on the front of the cover a neat representation of the turreted three-storey building reflected in the quiet waters of the inland lake, and on the back a list of the regulations observed in the management of the station.

In his introductory remarks the Director, who has already made his views known with regard to the importance of freshwater laboratories in the pages of several German scientific periodicals, gives a brief sketch of the advance already made in this direction in Italy, France, and America.

The first paper gives a list of the fauna at present known to inhabit the lake. This occupies seven pages; and fourteen names, being printed in italics, signify that they are new to science. The new species and genera are treated in detail in the second paper. The greatest number occur amongst *Rotatoria*, but additions are also made to the *Rhizopods*, *Heliozoa*, and *Infusoria*. No new forms appear to have been found amongst the crustacea, mollusca, or fishes.

---

[1] For recent experiments upon Magnetic Viscosity see a paper by J. Hopkinson, F.R.S., and B. Hopkinson in *Electrician*, September 9, 1892.

A third paper deals with the distribution and special natural history of the forms met with, and with the comparison of the plankton at different seasons.

There are no foot-notes through the number, but all references to literature are formed into a numbered table at the end. The plate, which is one of Klinkhardt's, of Leipzig, shows a number of the new forms discovered.

The investigations are almost entirely on the minute floating organisms, as must necessarily be the case at this date with all freshwater work not connected directly with pisciculture.

The British Journal Photographic Almanac for 1893. Edited by J. Traill Taylor. (London: Henry Greenwood, and Co., 1893.)

THIS annual volume contains, as usual, a vast amount of useful information gathered from workers in all the various applications of photography. After a brief summary, in which the editor refers to some of the chief advances made in the science of photography during the past year, mentioning, for instance, Mr. Dallmeyer's telephotographic lens, Mr. Willis's improvement in the platinotype process, &c., he devotes a few pages to "some photographic methods of book illustration." Then come short contributions in which everyone has something special to say, whether it relates to a new mounting medium, a permanent toning bath, or pinhole pictures, &c. They are far too numerous to mention individually, but will be found most interesting reading. "Epitome of Progress" is the title of a series of notes by Mr. Traill Taylor, in which he refers briefly, and in some cases at length, to new methods, remedies, &c., and instruments used in the practice of the art. The formulæ and tables are as numerous as ever, while all the other information, such as lists of photographic societies, &c., have been brought up to date. The volume is copiously illustrated.

Studies in Corsica. By John Warren Barry, M.A. (London: Sampson Low, Marston, and Co., 1893.)

MR. BARRY has twice visited Corsica, the first visit being of less than five months' duration, while the second extended from September 1882 to February 1885. He has thus had ample opportunities for the study both of the island and of its people, and in the present volume he sums up his impressions very brightly and pleasantly. Most readers will probably like best the chapters on life at Ajaccio, but they will also find much to interest them in what the author has to say about the Bush of Corsica and of the Mediterranean region.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Luminous Earthworms.

I HAVE recently received from a correspondent a statement which is sufficiently valuable to crave public attention. It opens up withal a very fascinating field of investigation, and one which, though it has by no means been altogether neglected by foretime naturalists, is as yet far from being fully understood.

Writing from Richmond, Surrey, the Rev. Alfred Geden, M.A., says:—"I have just heard of a phenomenon in the worm world which is new to me . . . My sister declares that one day last summer, in a village on the Thames, she saw a 'phosphorescent worm,' and describes the creature as about one and a half inches long, worm-like in all respects. My sister is sure it was not an ordinary glow-worm, with which she is perfectly familiar; and, moreover, she called the attention of a cousin to the creature at the time, who corroborates her account. Are there worms in England capable of emitting light besides the glow-worm? If so, are they at all common?"

In reply to a series of questions, I was able to elicit these further particulars:—"It was in a garden in the village of Long Wittenham, near Didcot, on a dark evening in the latter part of September last [1892], or the beginning of October. My sister's attention was attracted by the light on the ground, and she picked the worm up. While she cannot positively assert that she saw it in motion on the ground, it certainly wriggled in her hand. For a few seconds also after putting it down her fingers remained phosphorescent."

The notice of the public, so far as I have been able to ascertain, was first directed to this phenomenon among earthworms by Grimm in 1670, but scientific observation, as we now understand it, was then scarcely known. A century elapsed before any further record was made in the periodicals of Europe which I have consulted, then came a paper by Flaugergues in 1781. This article, which appeared in Lichtenberg's magazine, was written in German. In 1873 Cohn's observations on the same subject were published in the well-known *Zeitschrift für Wissensch. Zool.*, while numerous recent writers have further contributed to our knowledge, especially in relation to the Continental species.

Thus in 1872 an article appeared in the French Annals of Natural Science, by Panceri, entitled "Studies in the Phosphorescence of Marine Animals," in which he states that the luminosity observed in the case of certain (earth) worms is due to a secretion from the girdle, where special glands exist, and that by the evolution of light there was no perceptible raising of the temperature. In this respect, therefore, the earthworm's glow corresponds with that emitted by the firefly, Noctiluca, and glow-worm. One investigator at least has tested the colour and composition of the luminosity by the spectroscope, and says that it is not uni-coloured or monochromatic, but compounded chiefly of the red and violet rays. Other students regard the substance which produces the light as homogeneous.

In 1838 Eversmann published an article on a night-shining worm in Russian, and in 1871 an English naturalist named Breese delivered an address on the earthworm before the West Kent Natural History Society, from a meagre abstract of which we learn that he had spent some years on the subject of annelid luminosity, having studied it historically from the year 1805, when Viviani wrote on the phosphorescence of the sea, down to the date of his own delivery. According to Breese the luminosity exists in the excreted glutinous material with which the outer skin of the animal is covered.

More than one creature has at different times borne the name of the phosphorescent worm. In 1837 Dugès, a French writer, described a species under this name (*Lumbricus phosphoreus*), with a girdle extending from the 13th to the 16th segments, and a somewhat flattened body behind. After the lapse of exactly half a century this curious creature was examined again, and named by Giard Photodrilus, or the luminous worm. It has eight setæ, just as our common species have, but they are separate, and not in couples. There is no gizzard, nor does the lip dovetail into the segment behind. It is a small, transparent, rose-coloured worm, and decidedly phosphorescent.

In 1843 when the British Association met at Cork, specimens of an annelid were exhibited by Dr. Allman, which he had discovered in the bogs of the south of Ireland, and which was the cause of a luminous appearance. When irritated the worm gave out a phosphorescent light, which is said to have been much increased by exposing the creature to the vapour of alcohol. The light was of that peculiar soft greenish hue which is characteristic of the phosphoresence observed in light-giving animals, and familiar to most readers in connection with the glow-worm. Another gentleman was reported to have observed the same peculiarity in some annelids which exist in the bogs of Connaught. I have been unable to find any recent reference to or confirmation of these curious observations. Ten years later Mr. Henry Cox exhibited an earthworm which was phosphorescent at a meeting of the Literary and Philosophical Society of Liverpool, held November 14, 1853.

While few records of a trustworthy nature respecting the observation of luminous worms in Britain are available, a good deal has been done by our Continental fellow-workers. Vejdovsky, who wrote a very valuable work on the various species of annelids in 1884, gives us some results of his personal experience, which I believe have never been placed before the English reader. He says that he had the good fortune once at least to observe an interesting case of phosphoresence in connection with the brandling. It was one warm July night in the year 1881, when he was exploring a dung-heap. Naturalists do not usually work with kid gloves and diamond rings. Presently a spot of soft, bluish-white light appeared, which, however, was changeful and unsteady. Now it would disappear, then return anew and shine forth over a larger space, though never with a brilliant hue. He thereupon removed a portion of the manure from the spot where he had observed the luminosity, and found that the light appeared brighter, and shone for a longer time without disappearing, or before it migrated to another spot. By means of a lantern Vejdovsky was able to secure a large number of specimens of the brandling from the dung-heap, which he placed in a vessel for the purpose of subjecting them to careful observation. To his great surprise he found that his finger soon glowed in the darkness with the phosphorescence, which extended generally over the hand where it came into contact with the worms. It was therefore apparent that the luminosity was the product of a fluid secreted by the cutaneous glands, which had attached itself to the hand of the investigator, and now manifested itself in this curious way.

We have an interesting observation on the same subject by Prof. von Stein, which was published at Leipzig in 1883. One evening in the middle of September the Professor was spending some time with a circle of friends at a parsonage not far from Potsdam, when the conversation turned upon phosphorescence and the phenomena of light. Hereupon one of the younger members of the family—who are usually the keenest and most shrewd observers of Nature, and the best friends of the naturalist—observed that there were fountains in the adjoining gardens, the water from which was frequently observed to be full of light-bearing creatures when it was violently agitated. He regarded the affair at first simply as a hoax, or an attempt to make a fool of him—as people are ever ready to do with a hobby-rider—but ascertained eventually that the luminosity was due to the presence of a species of worm which possessed the property of shining when disturbed. As with Vejdovsky, so with Prof. von Stein, the finger which had come into contact with the worm continued to glow for some time after. What species of worm was under observation is not recorded.

It now becomes a question, What end could be served thereby? The philosopher no sooner learns a new fact than he begins to pry into the secret which lies beneath, and stands to it as cause to effect. We have analogy to guide us. The water worms may be compared with the marine animals which produce phosphorescence, while the brandling may be studied in the light of the glow-worm. It may be objected that as worms have no eyes there can be no advantage in their luminosity. But such an argument would be based on the erroneous assumption that a creature without eyes is incapable of receiving impressions from light. That worms are influenced by light is proved both by their habit of avoiding light, and by the experiments which have been carried out by various students. Darwin remarks that as worms are destitute of eyes he at first thought they were quite insensible to light. He found, however, that "light affects worms by its intensity and by its duration." Hoffmeister states that with the exception of a few individuals worms are extremely sensitive to light, and from my own observations I have been able to demonstrate that there are marked differences in the susceptibility of the different species—some being very much more susceptible than others.

Now it follows that if a number of species of worms lived together in one place, as they usually do in a manure heap, it would be a great advantage for a given species to possess a distinguishing feature, such as that of luminosity, to enable two individuals to discover each other's whereabouts, just as the male glow-worm detects the female by the light emitted from her upturned abdomen. We have, moreover, the fact that certain species of earthworm are characterised by a peculiar odour, which must be of great service in preventing promiscuous copulation and hybridity. Though earthworms are destitute of nasal organs they can detect odours, and though sightless they are affected by light.

Viewed in this light a new field of research is opened up which hitherto has been totally unworked, but which may be hoped to yield remarkable results if diligently, patiently, and intelligently tilled.

It would be an easy thing for any one living in the country, with access to an old manure heap, where the brandling (*Allolobophora fœtida*, Sav.) usually abounds, to ascertain whether such luminosity is of common occurrence, and it would be exceptionally valuable to record the period of the year, the state of the atmosphere, the age of the moon, and other data which would enable the specialist to arrive at a satisfactory conclusion. I shall be glad to receive communications, addressed "The Grove, Idle, Bradford," from observers who may find pleasure in such pursuits. HILDERIC FRIEND.

Quaternions and the Algebra of Vectors.

IN a recent number of this Journal (p. 151) Mr. McAulay puts certain questions to Mr. Heaviside and to me, relating to a subject of such importance as to justify an answer somewhat at length. I cannot of course speak for Mr. Heaviside, although I suppose that his views are not very different from mine on the most essential points, but even if he shall have already replied before this letter can appear, I shall be glad to add whatever of force may belong to independent testimony.

Mr. McAulay asks: "What is the *first* duty of the physical vector analyst *quâ* physical vector analyst?" The answer is not doubtful. It is to present the subject in such a form as to be most easily acquired, and most useful when acquired.

In regard to the slow progress of such methods toward recognition and use by physicists and others, which Mr. McAulay deplores, it does not seem possible to impute it to any want of uniformity of notation. I doubt whether there is any modern branch of mathematics which has been presented for so long a time with a greater uniformity of notation than quaternions.

What, then, is the cause of the fact which Mr. McAulay and all of us deplore? It is not far to seek. We need only a glance at the volumes in which Hamilton set forth his method. No wonder that physicists and others failed to perceive the possibilities of simplicity, perspicuity, and brevity which were contained in a system presented to them in ponderous volumes of 800 pages. Perhaps Hamilton may have intended these volumes as a sort of *thesaurus*, and we should look to his shorter papers for a compact account of his method. But if we turn to his earlier papers on Quaternions in the *Philosophical Magazine*, in which principally he introduced the subject to the notice of his contemporaries, we find them entitled "On Quaternions; or on a New System of Imaginaries in Algebra," and in them we find a great deal about imaginaries, and very little of a vector analysis. To show how slowly the system of vector analysis developed itself in the quaternionic *nidus*, we need only say that the symbols S, V, and ∇ do not appear until two or three years after the discovery of quaternions. In short, it seems to have been only a secondary object with Hamilton to express the geometrical relations of vectors,—secondary in time, and also secondary in this, that it was never allowed to give shape to his work.

But this relates to the past. In regard to the present *status*, I beg leave to quote what Mr. McAulay has said on another occasion (see *Phil. Mag.* June, 1892):—"Quaternions differ in an important respect from other branches of mathematics that are studied by mathematicians after they have in the course of years of hard labour laid the foundation of all their future work. In nearly all cases these branches are very properly so called. They each grow out of a definite spot of the main tree of mathematics, and derive their sustenance from the sap of the trunk as a whole. But not so with quaternions. To let these grow in the brain of a mathematician, he must start from the seed as with the rest of his mathematics regarded as a whole. He cannot graft them on his already flourishing tree, for they will die there. They are independent plants that require separate sowing and the consequent careful tending."

Can we wonder that mathematicians, physicists, astronomers, and geometers feel some doubt as to the value or necessity of something so separate from all other branches of learning? Can that be a natural treatment of the subject which has no relations to any other method, and, as one might suppose from reading some treatises, has only occurred to a single man? Or, at best, is it not discouraging to be told that in order to use the quaternionic method, one must give up the progress which he has already made in the pursuit of his favourite science, and go back to the beginning and start anew on a parallel course?

I believe, however, that if what I have quoted is true of vector methods, it is because there is something fundamentally wrong in the presentation of the subject. Of course, in some sense and to some extent it is and must be true. Whatever is special, accidental, and individual, will die, as it should; but that which is universal and essential should remain as an organic part of the whole intellectual acquisition. If that which is essential dies with the accidental, it must be because the accidental has been given the prominence which belongs to the essential. For myself, I should preach no such doctrine to those whom I wish to convert to the true faith.

In Italy, they say, all roads lead to Rome. In mechanics, kinematics, astronomy, physics, all study leads to the consideration of certain relations and operations. These are the capital notions; these should have the leading parts in any analysis suited to the subject.

If I wished to attract the student of any of these sciences to an algebra for vectors, I should tell him that the fundamental notions of this algebra were exactly those with which he was daily conversant. I should tell him that a vector algebra is so far from being any one man's production that half a century ago several were already working toward an algebra which should be primarily geometrical and not arithmetical, and that there is a remarkable similarity in the results to which these efforts led (see Proc. A.A.A.S. for 1886, pp. 37, ff.). I should call his attention to the fact that Lagrange and Gauss used the notation $(\alpha\beta\gamma)$ to denote precisely the same as Hamilton by his $S(\alpha\beta\gamma)$, except that Lagrange limited the expression to unit vectors, and Gauss to vectors of which the length is the secant of the latitude, and I should show him that we have only to give up these limitations, and the expression (in connection with the notion of geometrical addition) is endowed with an immense wealth of transformations. I should call his attention to the fact that the notation $[r_1 r_2]$, universal in the theory of orbits, is identical with Hamilton's $V(\rho_1\rho_2)$, except that Hamilton takes the area as a vector, *i.e.* includes the notion of the direction of the normal to the plane of the triangle, and that with this simple modification (and with the notion of geometrical addition of surfaces as well as of lines) this expression becomes closely connected with the first-mentioned, and is not only endowed with a similar capability for transformation, but enriches the first with new capabilities. In fact, I should tell him that the notions which we use in vector analysis are those which he who reads between the lines will meet on every page of the great masters of analysis, or of those who have probed deepest the secrets of nature, the only difference being that the vector analyst, having regard to the weakness of the human intellect, does as the early painters who wrote beneath their pictures "This is a tree," "This is a horse."

I cannot attach quite so much importance as Mr. McAulay to uniformity of notation. That very uniformity, if it existed among those who use a vector analysis, would rather obscure than reveal their connection with the general course of modern thought in mathematics and physics. There are two ways in which we may measure the progress of any reform. The one consists in counting those who have adopted the *shibboleth* of the reformers; the other measure is the degree in which the community is imbued with the essential principles of the reform. I should apply the broader measure to the present case, and do not find it quite so bad as Mr. McAulay does.

Yet the question of notations, although not the vital question, is certainly important, and I assure Mr. McAulay that reluctance to make unnecessary innovations in notation has been a very powerful motive in restraining me from publication. Indeed my pamphlet on "Vector Analysis," which has excited the animadversion of quaternionists, was never formally published, although rather widely distributed, so long as I had copies to distribute, among those who I thought might be interested in the subject. I may say, however, since I am called upon to defend my position, that I have found the notations of that pamphlet more flexible than those generally used. Mr. McAulay, at least, will understand what I mean by this, if I say that some of the relations which he has thought of sufficient importance to express by means of special devices (see Proc. R. S. E., for 1890–91), may be expressed at least as briefly in the notations which I have used, and without special devices. But I should not have been satisfied for the purposes of my pamphlet with any notation which should suggest even to the careless reader any connection with the notion of the quaternion. For I confess that one of my objects was to show that a system of vector analysis does not require any support from the notion of the quaternion, or, I may add, of the imaginary in algebra.

I should hardly dare to express myself with so much freedom, if I could not shelter myself behind an authority which will not be questioned.

I do not see that I have done anything very different from what the eminent mathematician upon whom Hamilton's mantle has fallen has been doing, it would seem, unconsciously. Contrast the system of quaternions, which he has described in his sketch of Hamilton's life and work in the *North British Review* for September, 1866, with the system which he urges upon the attention of physicists in the *Philosophical Magazine* in 1890. In 1866 we have a great deal about imaginaries, and nearly as much about the quaternion. In 1890 we have nothing about imaginaries, and little about the quaternion. Prof. Tait has spoken of the calculus of quaternions as throwing off in the course of years its early Cartesian trammels. I wonder that he does not see how well the progress in which he has led may be described as throwing off the yoke of the quaternion. A characteristic example is seen in the use of the symbol ∇. Hamilton applies this to a vector to form a quaternion, Tait to form a linear vector function. But while breathing a new life into the formulæ of quaternions, Prof. Tait stands stoutly by the letter.

Now I appreciate and admire the generous loyalty toward one whom he regards as his master, which has always led Prof. Tait to minimise the originality of his own work in regard to quaternions, and write as if everything was contained in the ideas which flashed into the mind of Hamilton at the classic Brougham Bridge. But not to speak of other claims of historical justice, we owe duties to our scholars as well as to our teachers, and the world is too large, and the current of modern thought is too broad, to be confined by the *ipse dixit* even of a Hamilton.

J. WILLARD GIBBS.

Glacial Drift of the Irish Channel.

IT seems of interest to record that the eurite or microgranite containing blue amphibole (Riebeckite), the rock noticed by Mr. P. F. Kendall in the drifts of the Isle of Man and Caernarvonshire, occurs abundantly in the form of small pebbles on the shore at Killiney, co. Dublin, doubtless derived from the "glacial gravels" of the coast. I have also found a pebble in the raised beach at Greenore, co. Down.

Mr. Teall's description of the rock of Ailsa Craig (*Mineralogical Magazine*, vol. ix. p. 219) enabled the very characteristic pebbles collected by Mr. Kendall to be referred to that mass as a source, or to formerly existing bosses south of or adjacent to it. As far as I am aware, all the material is in the form of pebbles, often only an inch in diameter. This is hardly likely to be its original condition, if removed by ice from Ailsa Craig, and is only one of many points that indicate a redistribution of our so-called "glacial" beds by subsequent action of rivers or other waters.

THE SACRED NILE.

THAT Egypt is the gift of the Nile is a remark we owe to the father of history, who referred not only to the fertilising influence of the stream, but to the fact that the presence of the Nile and its phenomena are the conditions upon which the habitability of Egypt altogether depends. That that part of Egyptian archæology and myth which chiefly interests astronomers is also the gift of the Nile is equally true.

The heliacal rising of Sirius and other stars at the time of the commencement of the inundations each year; all the myths which grew out of the various symbols of the stars so used, are so many evidences of the large share the river, with its various water levels at different times, had in the national life. It was, in fact, the true and unique basis of the national life.

In this the Nile had a compeer, or even compeers. What the Nile was to Egypt the Euphrates and Tigris were to a large region of Western Asia, where also we find the annual flood to have been in ancient times a source of fertility over an enormous area which is now desert, the plains being broken by the remains of the ancient canals.

What more natural than that Euphrates, Tigris and Nile were looked upon as deities; that the Gods of the Nile valley on the one hand, and of the region watered by the Euphrates and Tigris on the other, were gods to swear by; that they were worshipped in order that their benign influences might be secured, and that they had their local shrines and special cults.

The god sacred to the Euphrates and Tigris was called Ea. The god sacred to the Nile was called Hapi.

The name Hapi is the same as that of the bull Apis, the worship of which was attributed to Mena.[1] Certainly Mena, Mini, or Menes, as he is variously called, was fully justified in founding the cult of the river god, for he first among men appears to have had just ideas of irrigation; and I have heard the distinguished officers who have lately been responsible for the irrigation system of to-day speaking with admiration of the ideas and works of Menes.

Whether the Tigris had a Menes in an equally early time is a point on which history is silent; but, according to the accounts of travellers, the Tigris in flood is even more majestic than the Nile, and yet the latter river in flood is a sight to see—a whole fertile plain turned into, as it were, an arm of the sea, with here and there an island, which on inspection turns out to be a village, the mud houses of which too often are undermined by the lapping of the waves in the strong north wind.

There is no doubt that the dates of the rise of these rivers not only influenced the national life but even the religions of the dwellers on their banks. The Euphrates and Tigris rise about the time of the spring equinox—the religion was equinoxial, the temples were directed to the east. The Nile rises at a solstice—the religion was solstical and the solar temples were directed no longer to the east. To the Egyptians the coming of the river to the parched land was as the sunrise chasing the darkness of the night; the sun-god of day conquering the star-gods of night; or again the victorious king of the land slaughtering his enemies.

By no one, perhaps, have the impressions produced by the various phases of the river been so poetically described as by Osburn, a writer of vivid imagination, but it must be added that the facts detailed in his description are not exactly capable of being verified by engineering science. Osburn thus describes the low Nile:

"The Nile has shrunk within its banks until its stream is contracted to half its ordinary dimensions, and its turbid, slimy, stagnant waters scarcely seem to flow in any direction. Broad flats or steep banks of black, sun-baked Nile mud, form both the shores of the river. All beyond them is sand and sterility; for the hamseen, or sand-wind of fifty days' duration, has scarcely yet ceased to blow. The trunks and branches of trees may be seen here and there through the dusty, hazy, burning, atmosphere, but so entirely are their leaves coated with dust, that at a distance they are not distinguishable from the desert sand that surrounds them. It is only by the most painful and laborious operation of watering that any tint approximating to greenness can be preserved at this season even in the pleasure-gardens of the Pacha. The first symptom of the termination of this most terrible season is the rising of the north wind (the Etesian wind of the Greeks), blowing briskly, often fiercely during the whole of the day. The foliage of the groves that cover Lower Egypt is soon disencumbered by it of the dust, and resumes its verdure. The fierce fervours of the sun, then at his highest ascension, are also most seasonably mitigated by the same powerful agency, which prevails for this and the three following months throughout the entire land of Egypt."

Then at last comes the inundation:—

"Perhaps there is not in Nature a more exhilarating sight, or one more strongly exciting to confidence in God, than the rise of the Nile. Day by day and night by night, its turbid tide sweeps onward majestically over the parched sands of the waste, howling wilderness. Almost hourly, as we slowly ascended it before the Etesian wind, we heard the thundering fall of some mud-bank, and saw by the rush of all animated Nature to the spot, that the Nile had overleapt another obstruction, and that its bounding waters were diffusing life and joy through another desert. There are few impressions I ever received upon the remembrance of which I dwell with more pleasure than that of seeing the first burst of the Nile into one of the great channels of its annual overflow. All Nature shouts for joy. The men, the children, the buffaloes, gambol in its refreshing waters, the broad waves sparkle with shoals of fish, and fowl of every wing flutter over them in clouds. Nor is this jubilee of Nature confined to the higher orders of creation. The moment the sand becomes moistened by the approach of the fertilising waters, it is literally alive with insects innumerable. It is impossible to stand by the side of one of these noble streams, to see it every moment sweeping away some obstruction to its majestic course, and widening as it flows, without feeling the heart to expand with love and joy and confidence in the great Author of this annual miracle of mercy."

The effects of the inundation, as Osburn shows in another place, "exhibit themselves in a scene of fertility and beauty such as will scarcely be found in another country at any season of the year. The vivid green of the springing corn, the groves of pomegranate trees ablaze with the rich scarlet of their blossoms, the fresh breeze laden with the perfumes of gardens of roses and orange thickets, every tree and every shrub covered with sweet-scented flowers. These are a few of the natural beauties that welcome the stranger to the land of Ham. There is considerable sameness in them, it is true, for he would observe little variety in the trees and plants, whether he first entered Egypt by the gardens of Alexandria or the plain of Assouan. Yet is it the same everywhere, only because it would be impossible to make any addition to the sweetness of the odours, the brilliancy of the colours, or the exquisite beauty of the many forms of vegetable life, in the midst of which he wanders. It is monotonous, but it is the monotony of Paradise."

"The flood reaches Cairo on a day closely approximating to that of the summer solstice. It attains its greatest height, and begins to decline near the autumnal equinox. By the winter solstice the Nile has again subsided within its banks and resumed its blue colour. Seed-time has occurred in this interval. The year in Egypt divides itself into three seasons—four months of sowing and growth, corresponding nearly with our November, December, January, and February; four months of harvest from March to June; the four months of the inundation completing the cycle."

In order to show how the astronomy of the ancient Egyptians—to deal specially with them—was to a large extent concerned with the annual flood and all that depended upon that flood, and how the first solar year used on this planet, so far as we know, was established, it is important to study the actual facts of the rise somewhat closely, not only for Egypt generally, but for several points in the line some thousand miles in extent, along which in the earliest times cities and shrines were dotted here and there.

Time out of mind the fluctuations in the height of the river have been carefully recorded at different points along the river. In the "Description de l'Egypt" we find a full description of the so-called nilometer at Assuan (First Cataract) which dates from a remote period, perhaps as early as the 5th Dynasty.

In Ebers' delightful book on Egypt space is given to-the description of the much more modern one located at Rodah.

---

[1] Maspero, "Hist. Anc." xi. 10.

The nilometer, or "mikyas," on the island of Rodah now visible, is stated to have replaced one which was brought thither from Memphis at some unrecorded date. Makreezee in 1417, according to Ebers, saw the remains of the older nilometer.

The present mikyas is within a covered vault or chamber, the roof being supported on simple wooden pillars. In a quadrangular tank communicating with the river by a canal is an octagon pillar on which the Arabic measurements are inscribed. These consist of the pic (variously called ell or cubit) = 0·54 metre, which is divided into twenty-four kirats, in consequence of the rise of the river bed in relatively recent times, the nilometer is submerged at high Nile to a depth of two cubits.

The rise of the Nile can now be carefully studied, as gauges are distributed along the river. We have the Aswân gauge from 1869, the Armant gauge from 1887, the Suhag gauge from 1889, and the Asyût gauge from 1882. The distances of these gauges from Aswân are as follows:—

	Kilometres
Aswân	0
Armant	200
Suhag	447
Asyût	550
Rodah	941

The Rodah gauge is not to be depended on as the movements of the Barrage regulation destroy its value as a record. The heights of the zeros of these gauges above mean sea level are as follows:—

	Metres.
Aswân	84·158
Armant	69·535
Suhag	56·00
Asyût	53·10
Rodah	13·14

Great vagueness arises in there being no very obvious distinction between the gauge readings reached in summer and that from which the rise is continuous. There are apparently rainfalls in the end of spring of sufficient power to raise the Nile visibly in summer, just as muddy rises have been seen in winter to pass down the valley, leaving a muddy mark on the rocks at Aswân and Manfalût. Independently of the actual gauge-reading of the rise, there are facts about it which strike every beholder. At the commencement of the rise we have the *green water*. This occurs in June, but varies in date as much as the top of the flood varies.

From the fact that modern observations show that the very beginning of the rise, and the first flush, second flush, and final retirement vary, it seems evident that the ancient Egyptians could not have had any fixed zero-gauge or time for the real physical fact of the rise, but must have either deduced from a series of observations a mean period of commencement, or a mean arrival of the red water, or a mean rising up to a certain gauge.

First to deal with the green water. Generally when the rise of an inch or two is reported from the nilometer at Rodah, the waters lose the little of clearness and freshness they still possessed. The green colour is the lustreless hue of brackish water within the tropics, and only the finer class of modern filter can render such water clear. The colour is really due to algæ.

Happily, the continuance of this state of the water seldom exceeds three or four days. The sufferings of those who are compelled to drink it in this state, from vesicary disease, even in this short interval, are very severe. The inhabitants of the cities generally provide against it by Nile-water stored in reservoirs and tanks.

Col. Ross, R.E., noticed in 1887 and in 1890, when, owing to the slow retreat of the Nile, the irrigation officers had to hold back many basins in the Gizah province; and also in 1888, when the water remained long stagnant; that the basin-water got green—showed the algæ and smelt marshy, just as the June green water does.

Hence it has been argued that as the Nile-water in the bed of the stream—even in very slow-flowing back-waters—does not become green, the greenness must be produced by an almost absolute stagnation of the water. We know of great marshes up above Gondokoro, and hence it is thought that the green water of summer, which comes on suddenly, is this marsh-water being pushed out by the new water from behind, and that is why it heralds the rise. No one has so far minutely observed the gradual intrusion of the green water.

The rise of the river proceeds rapidly, and the water gradually becomes more turbid. Ten or twelve days, however, elapse before the development of the last and most extraordinary of all the appearances of the Nile, thus described by Mr. Osborn[1]:—"It was at the end of—to my own sensations—a long and very sultry night, that I raised myself from the sofa upon which I had in vain been endeavouring to sleep, on the deck of a Nile boat that lay becalmed off Benisoueff, a town of Middle Egypt.

"The sun was just showing the upper limb of his disc over the eastern mountains. I was surprised to see that when his rays fell upon the water, a deep ruddy reflection was given back. The depth of the tint increased continually as a larger portion of his light fell upon the water, and before he had entirely cleared the top of the hill it presented the perfect appearance or a river of blood. Suspecting some delusion, I rose up hastily, and looking over the side of the boat saw there the confirmation of my first impression. The entire body of the water was opaque and of a deep red colour, bearing a closer resemblance to blood than to any other natural production to which it could be compared. I now perceived that during the night the river had visibly risen several inches. While I was gazing at this great sight, the Arabs came round me to explain that it was the Red Nile. The redness and opacity of the water, in this extraordinary condition of the river, are subject to constant variations. On some days, when the rise of the river has not exceeded an inch or two, its waters return to a state of semi-transparency, though during the entire period of the high Nile they never lose the deep red tinge which cannot be separated from them. It is not, however, like the green admixture, at all deleterious; the Nile water is never more wholesome or more deliciously refreshing than during the overflow. There are other days when the rise of the river is much more rapid, and then the quantity of mud that is suspended in the water exceeds, in Upper Egypt, that which I have seen in any other river. On more than one occasion I could perceive that it visibly interfered with the flow of the stream. A glassful of it in this state was allowed to remain still for a short time. The upper portion of it was perfectly opaque and the colour of blood. A sediment of black mud occupied about one quarter of the glass. A considerable portion of this is deposited before the river reaches Middle and Lower Egypt. I never observed the Nile water in this condition there, and indeed no consecutive observations exist of the reddening of the water. It is quite clear that the reddening cannot come from the White Nile, but must be the first floods of the Blue Nile and the Atbara coming down."

Rate of Rise of the Nile.—The rate in flood is $1\frac{3}{4}$ days from Wady Halfa to Aswân and six days from Aswân to Rodah (941 kilometres). In very high Niles this is perhaps accelerated to five days. In the early flood rising from, say, one cubit Aswân to six cubits, where there are many dry sandbanks, and the spreading out of the river is considerable, and there is an absence of overlapping flushes from behind, the rate goes up to fifteen days. There is a very great difference in time and rate between Green and Red Nile. The rise is 45 ft. at Aswân, 38 at Thebes, and 25 at Cairo.

---

[1] "Monumental Egypt," chapter i.

From the data obtained at the gauges named which have been kindly forwarded to me by Mr. Garstin, the U.S. of State of the Public Works Department of Egypt, I have ascertained that the average time taken by the flood to travel now between Thebes and Memphis is about nine days. Although the river bed is now higher than formerly, the land around Thebes, according to Budge, having been raised about nine feet in the last 1700 years, still the same elevation has taken place at Memphis, so that no difference in the velocity of the stream would be produced by this cause.

The great difficulty experienced in understanding the statements generally made concerning the Nile-rise arises from the fact that the maximum flood is as a rule registered in Cairo upwards of 40 days after the maximum of Aswân.

For the following account of how this is brought about I am indebted to the kindness of Col. Ross, R.E. :—

"The behaviour of the flood at the Aswân gauge is as follows: Between August 20 and 30 a good average gauge of 16 cubits is often reached, and between August 27 and September 3 there is often a drop of about 30 centimetres. The August rise is supposed to be mostly due to the Blue Nile and Atbara River. Between September 1 and 8 the irrigation officers generally look for a maximum flood-gauge of the year at Aswân. This is supposed to be the first flush of the White Nile. In the middle of September there are generally two small flushes, but the last twenty days of September are generally distinctly lower than that of the first week. The final flush of the Nile is seldom later than the 21st to 25th September.

"All this water does not merely go down the Nile; it floods the different basins. The opening of these basins begins from the south to the north. This operation is generally performed between the 29th September and the 22nd October. The great Central Egypt basins are not connected with the Nile for purposes of discharge into the river between Asyût and near Wasta, or a distance of 395–90 kilometres = 305 kil.

"The country in the middle or Central Egypt is broad, and thus there is an enormous quantity of water poured out of these basins into the lower reaches of the river about the 20th October, which seriously raises the Nile at Cairo, and in a good average year will bring the Cairo gauge (at Rodah) up to the maximum of the year on or about October 22, and hence it is that the guide books say the Nile is at its highest in the end of October.

"A gauge of 16½ cubits at Aswân while the basins are being filled does not give more than 21 cubits at Rodah (Cairo), but as the basins with a 16½ gauge will fill by the 10th September, it follows that a 16½ to 16 cubit gauge at Aswân will not give a constant Cairo gauge, as the great mass of water passes by the basins and reaches Cairo. Hence we have frequently the paradox of a steady or falling gauge at Aswân showing a steady rise at Cairo.

"If the gauge at Aswân keeps above 16 cubits to near the end of September, the basin-emptying is much retarded, as the emptying at each successive basin fills the Nile above the 16 cubit level; *hence the lower halves of the chains of basins do not flow off*, and thus when the great Middle Egypt basins are discharged, they do not raise the Nile so much as they do when the last half of September Nile is below 16 at Aswân.

"In years like 1887 and 1892, which differ from each other only in date of maximum gauge at Aswân, the river, having filled the basins in 15 to 20 days instead of in 25 to 30 days, comes down to Cairo in so largely increased a volume that a really dangerous gauge of 25 cubits at Cairo is maintained for over a fortnight (the average October gauge in Cairo is about 23 cubits), and from September 10 to October 25 the river remains from 24 cubits to 25½ cubits, and the Middle Egypt basins discharge so slowly that the opening day is hardly traceable on the Cairo gauge.

"In the 1878 flood, which was the most disastrous flood possible, the river rose in the most abnormal fashion, and on October 3 attained 18 cubits at Aswân. This breached the Delta, and in addition so delayed the Upper Egypt basins emptying from the reason before given that the wheat was sown too late, and got badly scorched by the hot winds of March and April."[1]

J. NORMAN LOCKYER.

THE LANDSLIP AT SANDGATE.

THE causes of landslips are in general so well known and the localities which are liable to them so clearly defined on geological principles that when on Monday, March 6, the public were startled by the news of a landslip at Sandgate, the probability would be that geologists who knew the district would be by no means surprised, more particularly as the locality of the catastrophe is in the midst of a typical section shown in many of the textbooks, and the town itself gives its name to a subdivision of the Cretaceous rocks.

The event, however, does not appear to have been expected, and since it has happened conjectures as to its cause have been numerous; but the true explanation has been wanting.

The series of rocks which, in descending order, form the country about Sandgate are the Folkestone beds, the Sandgate beds, the Hythe beds, and the Atherfield clay. Amongst these it is natural to look in the first instance for the presence of clays, as the probable origin of a landslip, though very loose sands have also been known to give way. The Folkestone beds are for the most part sand and they are bound together by bands of grit. Moreover, they are above the affected area. The Hythe beds are likewise characterised by bands of hard limestone, separated by calcareous sands. There are left the Atherfield clay, whose nature is indicated by its name, and the Sandgate beds.

The most recent description of these is that of W. Topley, F.R.S., in the *Comptes Rendus* of the Congrès Géologique International, 1888, in which they are briefly characterised (p. 257) as "*Argiles vertes et sables.*" The same writer's description of them in 1883 (quoted also by H. B. Woodward in 1887) is somewhat different, but in his "Geology of the Weald," 1875, they are said to consist of dark clayey sand and clay, the total thickness being given as 80 ft. In his more detailed description, however, Mr. F. G. H. Price divides these 80 ft. into four parts, the lowest 20 ft. being all "clayey beds" (Proc. Geol. Assoc., vol. iv. p. 554). In a still earlier account by Prof. Morris (*l.c.* vol. ii. p. 41) we have the following interesting statement:—"The dark-greenish sub-argillaceous sands, known as the Sandgate beds, rise on the shore at a short distance west of Folkestone. The low undercliff which skirts the shore from Folkestone nearly to Hythe owes its origin to the presence of these beds, which from their retention of water and slight coherency of structure have caused the frequent subsidence of the beds above."

It would appear, then, that there are two possible sources of the slipping—the Atherfield clay and the clayey bands of the Sandgate beds, and thus much was indicated at once by Mr. F. W. Rudler (*Daily Graphic*, March 8).

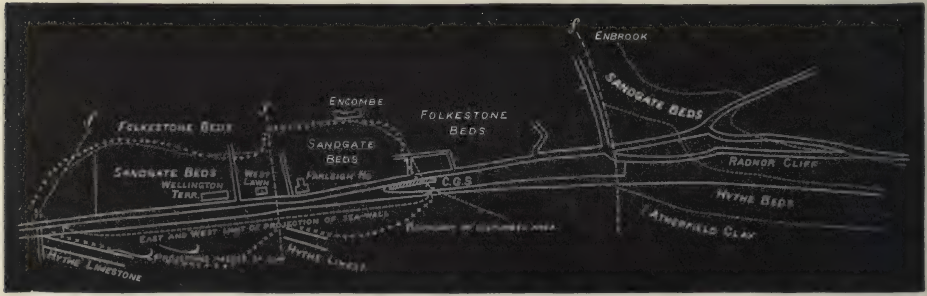
On a personal examination of the area the whole history of the subsidence becomes clear enough. At

---

[1] The modern Egyptians still hold to the old months for irrigation. 7 Tuba=January 15 is commencement of wheat irrigation; 30 Misra is the last safe date for sowing maize in the Delta; 1st Tut is the date of regulating the bridges=September 8 in Upper Egypt.

Sandgate itself neither the Atherfield clay nor the Sandgate beds are well exposed, but on the seashore between there and Folkestone we meet with the white-weathering massive limestone of the Hythe beds at Mill Point, and to the west of it. They are here dipping east at a moderate angle, and if this dip is continued, as the beds rise to the west, there would be room for the 60 feet of them which are seen at Hythe, between their probable outcrop in the lower part of the Enbrook Valley and low-water mark, opposite its debouchure. It must be here, if anywhere, that the recorded appearance of Atherfield clay occurs—for the state of things above described must here be terminated by a fault, as will be presently explained, and nowhere else along the coast till Sandgate is entirely passed can this clay occur within 40 yards seaward of low-water. On the east side of Enbrook, however, there is no landslip, and the actual landslip is thus shown to have nothing to do with the Atherfield clay.

Above the strong bands of Hythe limestone, however, west of Mill Point, are seen about 20 feet of soft, crumbling clay, occupying the base of the low cliff and becoming sandier above, as described by Mr. Price, and it is easily seen that the bottom of the Enbrook Valley is excavated in clay. The same clay is admirably seen on the other side of Sandgate, in the first cutting beyond Hythe Station on the branch line from Sandling Junction, so that though it is not now well exposed in Sandgate itself, we may be sure that it forms a continuous band immediately above the Hythe limestone.



Now, continuing to examine the coast below Sandgate on the west side of Enbrook we find an outcrop of Hythe limestone nearly opposite Farleigh House. Here also it has a dip towards the east; but it has also an abnormally high dip—perhaps 10°—inshore; such a dip in itself indicates a dislocation in the neighbourhood, but independently of this, the position of this band at the same level as that at Mill Point, while both bands dip, proves that there is a fault between the two, probably along the Enbrook Valley, with a downthrow on the west. This brings down the clay band at the base of the Sandgate beds to the sea level immediately to the east of the limestone above mentioned, and further on, to the east of the coastguard station, the sandy beds of the Folkestone series, which may, however, have slipped.

Going further west, we find the same band of Hythe limestone exposed on the sloping shore, having a similar easterly dip; but not so great an inshore dip, which, unless this were a lower band of Hythe limestone (which other observations negative), proves a second fault between these two, with a downthrow also to the west, but of smaller amount. Further west again, and just beyond the town, the sandy Folkestone beds are found at a lower level than they should be if the stratification were regular, and in the slight valley intervening there is a spring, which may indicate the line of another fault; or it may be that all this is only a surface slip; but, in any case, Folkestone beds occupy the actual surface.

The strike faults thus indicated are only what we might expect if the strata broke, as they so often do, during their upheaval. It is plain that such faults will rather complicate the surface exposure of the clayey rocks which overlie the Hythe limestone. Now, if we allow some 100 feet for the Sandgate beds, so as to include in the title all that portion of the series above the clay band at the base, which is not strengthened by the occurrence of indurated bands, and draw, from the purely geological considerations detailed above, the boundary of their surface exposure, which will not be an entirely simple one, *it exactly coincides with the boundary of the disturbed area.* Thus the upper boundary commences just beyond the town on the west, and runs very nearly along the line of the most westerly fault, till the latter has Folkestone beds on both sides of it; it then changes direction, and runs parallel to the outcrop of the Hythe beds on the foreshore, sloping down to a point above West Lawn, that is, to the probable position of the second fault; it is then thrown back along the probable line of that fault. It then again changes its direction and runs at first parallel to the second outcrop of the Hythe limestone, afterwards sloping down rapidly to the shore, so as to follow what would be probably the line ot outcrop of the first hard band in the possibly slipped mass of the Folkestone beds. The conclusion from this seems inevitable. *The whole disturbance is due to a motion of soft Sandgate beds where they are unprotected by the overlying hard bands of the Folkestone beds.*

The nature of the motion can be determined by an examination of its upper, and particularly of its lower limit. The greatest amount of visible disturbance has taken place along the upper limit; here the ground is seen to have slipped downwards and forwards. This might be caused by the collapse of an underground hollow if such a thing were possible, but the loose sandy and clayey nature of the rocks would not admit of such a hollow being formed, and the thick clay band at the base would effectually shield the Hythe limestones from chemical erosion. The lower limit, however, shows very plainly that the motion has been a simple slip in a south-east or east-south-east direction. In the first place the westerly band of Hythe limestone on the foreshore which abuts against a concrete groin is absolutely unmoved, and the sea-wall above is quite intact (which is a second proof—if, after what has been said above, any further proof were needed, that the Atherfield clay has nothing whatever to do with the matter). In the second place, immediately to the east of this outcrop, the sea-wall has bulged forward by about three feet, as shown by the next, wooden, groin, and near low-water mark the overlying clay is seen to be bulged up, so as to form a mound on the foreshore, which is being rapidly destroyed by the sea; while further east, opposite the end of Wellington Terrace, the overlying more sandy clays are also seen bulged up. Along the main road also, in front of West Lawn, on the western side of the supposed fault, the surface has been squeezed up. On the eastern side of this fault, further cracks, indicating a forward motion, are seen at the entrance to Encombe grounds; and, finally, the Coast Guard houses and the wall in front bulge forward at least three feet, and probably more, and the two sides of the street opposite have been squeezed together.

Thus the whole disturbance has been caused by the slipping downwards of the overlying soft beds over the inclined plane formed by the basement band of clay which rests on the Hythe limestone as a firm foundation, the direction of motion having been somewhat modified by the resisting mass of rock which lies to the east, and by the natural tendency of the sliding mass to take the shortest course to a lower level.

It is thus seen that the circumstances of the locality exactly fulfil the usual geological conditions for a landslip—*i.e.* a sloping bed of clay, which is liable to become slippery, and whose dip is towards the lower surface level where the overlying rocks find no support. Hence it may safely be said that any geologist, whose attention had been specially directed to the question, could have predicted that such an occurrence was extremely likely, sooner or later, to happen. There is, however, one necessary condition, which does not depend on the lie of the strata and the form of the ground, and that is that the clay should become slippery. This condition will probably account for the fact that in the area to the east of the Enbrook fault where all the other conditions are satisfied, *i.e.* in the neighbourhood of Radnor Cliff, no landslip has occurred. Clay is of course rendered slippery by the access of water. Now water will easily find its way through sandy strata, and there are sandy beds even in the lower portion till we come to the band of clay itself. As this is equally true in both localities the only difference can be in the amount of water.

Now there is a natural tendency for water to run down the dip slope of the strata, especially when there are hard bands as in the Folkestone beds, so that in this case most of the water will come from the west, and this source is cut off from the Radnor Cliff side by the Enbrook Valley, to the east of which there is little or no gathering ground; but to the west and north-west of the disturbed area there is a wide expanse of high ground, mostly rising 100 feet above the level of the Sandgate beds, and the water which falls on this finds its easiest outlet into these beds. They are therefore exactly in a position to get waterlogged, and that they are so is shown by the numerous springs that may be seen along the upper limit of the disturbed area.

The above considerations show that this area always has been and always will be liable to landslips. The lie of the beds which produces this liability cannot be altered by human agency, but the liability may be reduced to a minimum by a suitable system of drainage, which shall prevent the access of so large a body of water to so dangerous an area.

In the meantime the inhabitants of Sandgate may congratulate themselves that the shoreward dip of the beds and fault which breaks their continuity have reduced the result of the slip to a minimum, and rendered possible the remarkable circumstance that, though it happened in an area covered with houses, not a single house has been actually thrown down—not a single life lost.

As to the *immediate* cause of the occurrence, it is perhaps scarcely necessary to look for it. The landslip must necessarily have occurred at some time or another, and the conditions must for a long time have been gradually accumulating, by the constant access of water and the wearing action of the sea. If, however, the free discharge of the water from the beds has been in any way interfered with—by the stoppage of wells, or the construction of imperforate sea-walls—this would doubtless tend to the acceleration of the catastrophe; and an exceptionally wet season, like that we have recently experienced, might suffice to determine it. It would be scarcely necessary to add, except that the idea has been mentioned in the House, that the blowing up of the *Benvenue* and the *Calypso* could have absolutely nothing to do with it: in the first place, because the scene of the explosions was to the west of the disturbed area, and cut off from it by the massive Hythe beds, which are absolutely undisturbed—to say nothing of the Atherfield clay at sea which must necessarily intervene; secondly, because such a cause could not require several months to operate; and, lastly, because a vibration would rather tend to cause such beds to settle than to slip.

J. F. BLAKE.

NOTES.

PROF. VIRCHOW will deliver the Croonian Lecture this afternoon, and in the evening he will be entertained at the public dinner which is to be given in his honour at the Hôtel Métropole. It may at the same time be noted that an important scientific work, in three volumes, has just been issued by the Berlin publisher, August Hirschwald, in memory of the celebration of Prof. Virchow's seventieth birthday. The work is entitled "Internationale Beiträge zur Wissenschaftlichen Medicin," and among the contributors to it are Sir James Paget, Sir Joseph Lister, and other English writers.

A MOVEMENT has been started for the celebration of the hundredth anniversary of the birth of the illustrious Russian mathematician, Lobatcheffsky, who was described by the late Prof. Clifford as "the Copernicus of geometry." He was born on October 10, 1793. It is proposed that honour shall be done to his memory at the Imperial University of Kasan, with which he was for many years connected as a professor and as rector. The Physico-Mathematical Society of the University, which has taken the matter in hand, hopes to be able either to establish a prize with Lobatcheffsky's name for researches in mathematics, or to erect a bust of the great investigator in the University buildings. If the funds suffice, both of these things will be done. Subscriptions should be sent to the Physico-Mathematical Society, Kasan.

THE German Congress of Naturalists and Physicians, which was postponed last year on account of the outbreak of cholera, is to meet this year at Nürnberg.

PROF. W. C. ROBERTS-AUSTEN, F.R.S., chemist and assayer to the Royal Mint, and Mr. Thomas Bryant, President of the Royal College of Surgeons, have been elected members of the Athenæum Club, under the provisions of the rule by which the Committee is empowered to elect annually nine persons "of distinguished eminence in science, literature, the arts, or for public services."

THE half-yearly general meeting of the Scottish Meteorological Society was held at Edinburgh on Monday, March 13. The council of the society submitted its report, and the following papers were read:—On the temperatures of Lochs Lochy and Ness as affected by the wind, by Dr. Murray; mean temperature of London from 1763 to 1892, by Dr. Buchan; hygrometric researches at the Ben Nevis Observatories, by A. J. Herbertson.

WE understand that an enormous iron meteorite weighing nearly one ton (2044 lbs.) has just been received by Mr. J. R.

Gregory, of Charlotte Street, Fitzroy Square, from the same locality as the one described by him in NATURE in November last; it is 4 feet 2 inches long by 2 feet 3 inches wide and 20 inches thick. It comes from Youndegin in Western Australia.

THE secretary of the Physical Society asks us to say that in the report of the Society's annual general meeting (NATURE, March 2, p. 429) the name of Mr. J. T. Hurst was wrongly included in the list of members lost by death.

ATTENTION is called in the North Atlantic Pilot Chart to the fact that the great astronomical event of the month of April—the eclipse of the sun on April 16—will have certain features of special interest to the science of marine meteorology. Masters of vessels and observers who may be within the limits of the visibility of this eclipse are earnestly requested to make reports of their observations. The chart shows graphically the path of the total eclipse, the northern limit of visibility, and curves showing at what places the eclipse begins at 1 hour, 2 hours, and 3 hours, and when it ends at 3 hours, 4 hours, and 5 hours, Greenwich mean time, April 16. It is pointed out that there are observations which any one can make, and that these may prove to be of great interest and value. The following are particularly desired: (1) any changes in the clouds accompanying changes of temperature during the eclipse; (2) reading of the barometer every half hour from 11.30 to 5.30 G.M.T., while in the path of total eclipse; (3) temperature of the air, both wet and dry bulb, during the same interval; (4) any peculiar appearance of light during the eclipse; (5) the altitude and azimuth of any faint comet that may be detected during the eclipse.

THE weather during the latter part of last week was exceptionally fine over England, the daily maxima being frequently above 60°, and reaching 66° in the midland counties on Sunday, a temperature which is nearly 20° above the mean maximum for the time of year. The nights, however, were very cold, owing to the radiation under a clear sky; in some localities the readings on the grass were as low as 23° to 25°, and little, if any, above freezing in the shade. These conditions were occasioned by the distribution of atmospheric pressure, there being a well-defined anticyclone over the southern parts of England and over part of the continent. But in Scotland and Ireland the weather was much less settled; low-pressure areas lay off the north of Scotland, causing gales and occasional rainfall, while hail occurred at Wick on Friday. At the beginning of the present week the barometer fell decidedly, the anticyclone moved to the eastward, and the type of weather underwent a complete change, fog becoming prevalent at many places in the southern parts of the kingdom, and on Tuesday a new depression reached the north of Scotland, accompanied by rainy and unsettled weather generally. The official report for the week ending the 11th instant showed that bright sunshine was more prevalent than it has been for many weeks, and that it exceeded the average amount in all districts; also that there was a great deficiency in the amount of rainfall in all districts, except in the north of Scotland.

Das Wetter for February contains some particulars respecting the extraordinarily high barometer readings during January. At the commencement of that month the isobar between Lapland and Finland indicated the unusual height of 30·9 inches, which increased to 31·1 on the 3rd. On this day the centre of high pressure was in the vicinity of the White Sea, the reading at Archangel being 31·2 inches, and at Kargopol, on the Onega, 31·3 inches. Such high readings in those parts in winter are the more noteworthy, owing to the frequent passage of depressions over the north of Europe during that season. Subsequently the high pressure area shifted to Eastern Siberia, where high readings are more usual. On January 12 the pressure at Irkutsk exceeded 31·5 inches, and on the next day it reached 31·7. According to Dr. Hann, such a high reading had only been recorded once before, viz. on December 16, 1877, at Semipalatinsk. But on the morning of January 14, the reading at Irkutsk, reduced to sea level and corrected for gravity, attained the unprecedented height of 31·8 inches. So far as it is known this is the highest reading that has ever been recorded on the globe. These high pressures were also accompanied by very low temperatures. On January 14 the thermometer at Irkutsk fell to minus 51°·3, or about 40° below the mean for the time of year. In the north of Sweden the thermometer fell to minus 76°, or 38° below the freezing point of mercury.

SOME shocks of earthquake have lately been felt at Quetta. Two occurred on February 13 at 9.50 p.m., and another shock on the 14th at about 3 a.m. These shocks caused a considerable scare, and many people rushed out of doors, the condition of many houses in Quetta being anything but safe. The *Pioneer Mail* says that several houses have since fallen at Quetta, and a number of people have been injured, and two killed thereby.

DR. D. D. CUNNINGHAM is carrying on a series of microscopical investigations into the Indian potato blight. Elaborate experiments are also being made in the practical treatment of the crop and of diseased soils. The results, according to the *Pioneer Mail*, are expected to be important, and will be made public in due course.

IT appears from the Ceylon Census Report for 1891 that the bulk of the population of the island live by agriculture. The proportion of the agricultural class to the general population is in Ceylon 70·5; in India 64·09; in England and Wales 15·44. Next in order of number comes the industrial class, which includes something less than one-sixth, and after it the commercial class, holding one-twentieth. The *Ceylon Observer* notes as remarkable the fact that in the Southern Province there is a larger Sinhalese industrial population than in any other province—a result, it is supposed, attributable to the large number of people engaged in utilising the products of the cocoa-nut tree, with a certain number of workers in jewellery, tortoise-shell, &c.

TWO Akka girls, who were rescued from Arab capturers by Dr. Stuhlmann and his companions, have been brought to Europe, and will remain in Germany for some months. In the summer they will be taken back to Africa, where they will be placed in some mission house, or otherwise provided for. They are supposed to be between seventeen and twenty years of age. A correspondent of the *Daily News*, who saw them at Naples, says they are well proportioned, and as tall as a boy of eight years of age. Their behaviour is "infantile, wild, and shy, but without timidity." One of them was always cross, bending her head, and glaring from beneath frowning brows; while the other often laughed joyously, was pleased with bead bracelets and other trinkets given to her, and expressed by a queer sniff of her flat nose her appreciation of some chocolate bonbons. After making "a capital dinner on rice and meat," they greatly enjoyed the sunshine in a pretty garden, where they gradually grew more confident, and finally allowed themselves to be photographed arm-in-arm with the little son of their hostess. "The coquettish one shook with laughter, and seemed to guess that a process was going on flattering to her vanity, while the cross one still looked gloomy and suspicious. They showed neither wonder nor admiration of the people and things around them in the artistically furnished house and tasteful garden; their eyes, though large and lustrous, have less expression than the ugly eyes of a monkey." These interesting representatives of one of the pygmy races of the world are to be presented to various scientific societies in Berlin.

AN interesting address delivered by M. Paul Richer at the last meeting of the French Association for the Advancement of Science is printed in the current number of the *Revue Scientifique*. The subject is the relation of anatomy to art. M. Richer gives a lucid account of the canons of the human figure which have been adopted during various periods in the history of art, referring especially to those of the Greek sculptors Polycleitos and Lysippos and to those of Leonardo da Vinci, Albert Dürer, and Jean Cousin. He then shows that we now have materials for the establishment of a scientific type of the proportions of the human body, so far at least as the white race is concerned. This type is not, of course, to be reproduced in the works of artists; but M. Richer thinks it may be of real service to them as a guide in the appreciation of the proportions of the different models they have from time to time to study.

MR. A. C. MACDONALD contributes to the *Agricultural Journal* of Cape Colony a full and interesting account of what has been done to develop the dairy industry in Great Britain. Speaking of the same industry in Cape Colony, he says that it is there only in its infancy. This is largely due to the difficulty which farmers otherwise favourably circumstanced have had hitherto to contend with in the transport of their dairy products to market in good condition. Now, however, the extension and union of railways have more or less removed this difficulty, and many of the leading farmers, taking advantage of the facilities afforded by such extension and union, have greatly increased their butter production. In fact, within the last two years the increase in the manufacture of this commodity in the colony has been very large. Mr. Macdonald sees no reason why in districts such as Alexandria, Bathurst, Peddie, Victoria East, Fort Beaufort, Albany, Port Elizabeth, Uitenhage, and East London, where it has now become difficult to farm with small stock or grow grain profitably, dairying should not prove as great a success as it has done in the Australian colonies, which in some respects are not so favourably situated as Cape Colony, provided that the same means are used.

THE nucleus of a palæontological collection was formed at the Johns Hopkins University five years ago by Dr. W. B. Clark from the deposits of the Atlantic coastal plain. He was able to gather together a very large amount of material owing to the richness of the formations in fossils and their accessibility to the city of Baltimore; and since that time additions have been made each year by collection and by exchange with the National and State Surveys and educational institutions. We learn from the new number of the University's "Circulars" that there was a greater increase of the fossil collections during the past year than during any preceding one. This was accomplished mainly by exchange and purchase, although a considerable amount of material was collected in the field. Among the more notable additions was a collection sent in exchange by Mr. G. F. Harris, of the British Museum. This collection is very rich in tertiary fossils, illustrating many of the typical English localities. It contains hundreds of species from the Eocene, Oligocene, and Pliocene of England. Owing to the fact that the richest and finest collections of the Palæontological Museum of the University are from the American tertiary, these English tertiary fossils are said to be of the highest interest and usefulness to students of geology.

AN interesting paper on Artesian wells as a water supply for Philadelphia was lately read by Prof. O. C. S. Carter before the chemical section of the Franklin Institute. A long-continued drought caused much inconvenience at Philadelphia during the summer of 1892, so that the inhabitants would be likely to welcome any practicable suggestion for providing them with new supplies of fresh and wholesome water. Prof. Carter, after careful investigation, strongly recommends the use of artesian wells, the water of which, he says, would be of considerable quantity and excellent quality.

AN instrument for measuring densities of liquids, which for simplicity can hardly be surpassed, is described by A. Handl in the *Wiener Berichte*. It consists of two glass tubes joined by an indiarubber tube. One of them is 30 cm. long and about 1 cm. wide, and bears two marks scratched into the glass at a distance of 20 cm. This tube is immersed in the liquid to be examined up to the lower mark. Meanwhile the other tube is totally immersed in water. On pulling it out the liquids in both tubes rise until that in the first tube reaches the second mark. The height of the water-column, read off on a suitable scale, measures the density of the liquid.

MESSRS. SIMPKIN, MARSHALL AND CO have issued Miss Eleanor A. Ormerod's "Report of Observations of Injurious Insects and Common Farm Pests, during the Year 1892, with Methods of Prevention and Remedy." This is Miss Ormerod's sixteenth report. She notes that during 1892 most of the insect infestations commonly injurious to field crops and fruit were present to such an extent as to cause inquiry as to their nature and as to methods of prevention, but that for the most part they did not affect large districts to a serious extent.

A NEW scientific journal devoted to the interests of general systematic botany has made its appearance, published at Chambésy, near Geneva, under the title *Bulletin de l'Herbier Boissier*.

A BOTANICAL DICTIONARY, by Mr. A. A. Crozier, has just been published by Holt and Co., of New York, containing definitions of over 5000 words.

MESSRS. PERKEN, SON, AND RAYMENT have issued an illustrated catalogue of photographic apparatus, magic lanterns, and optical instruments.

MESSRS. WHITTAKER AND CO. will issue in their Specialists' Series a work on "The Dynamo," by C. C. Hawkins and F. Wallis, and a new edition of Sir David Salomons' work on "The Management of Accumulators." They have also in preparation in the Library of Popular Science an introductory work on "Electricity and Magnetism," by S. Bottone, and one on "Geology," by A. J. Jukes-Browne. Mr. Perren Maycock has completed the second part of his work on "Electric Lighting and Power Distribution," and it will be issued in a few days. An illustrated work on "British Locomotives," by C. J. Bowen Cooke, of the London and North-Western Railway, is in the press, and will probably be issued in May. Messrs. Whittaker have also in the press a new work by J. Horner ("A Foreman Pattern-Maker"), entitled "The Principles of Fitting," and the second part of Mr. Brodie's "Dissections Illustrated."

MESSRS. GRIFFIN AND CO. announce "A Manual of Dyeing," by Dr. Knecht, Mr. Chr. Rawson, and Dr. R. Loewenthal; "Oils, Fats, Waxes, and Allied Materials, and the Manufacture therefrom of Candles, Soaps and other Products," by Dr. C. R. Alder Wright; "Painters' Colours, Oils, and Varnishes, by Mr. Geo. H. Hurst; "Griffin's Electrical Price-Book," edited by Mr. H. J. Dowsing; the tenth annual issue of the "Year-Book of Learned and Scientific Societies;" "A Treatise on Ruptures," by Mr. J. F. C. Macready; "Forensic Medicine and Toxicology," by Prof. Dixon Mann; "The Medical Diseases of Children," by Mr. Bryan Donkin; "A Medical Handbook for the Use of Students," by Mr. R. S. Aitchison; "The Physiologist's Note-Book," by Dr. W. Hill; and "A Text-Book of Biology," by Prof. J. R. Ainsworth Davis.

MESSRS. L. REEVE AND CO. have in preparation a new work on the British Aculeate Hymenoptera from the pen of Mr.

Edward Saunders, uniform with the same author's work on the Hemiptera Heteroptera, just completed.

THE extreme difficulty which is experienced in the separate identification of the typhoid bacillus and the *B. coli communis* in consequence not only of their great resemblance microscopically, but also in the appearances to which they give rise when grown in artificial culture media, has caused much doubt to be cast upon the alleged detection of the former in water. It is well known that the *B. coli communis* is an almost constant attendant upon the typhoid bacillus, being normally present in the alimentary canal, and being, moreover, frequently found in large numbers in polluted streams and contaminated well-water. In nearly all cases, therefore, where a water is suspected of harbouring the typhoid bacillus the *B. coli communis* may also be expected to be present. Unfortunately, the many methods which have been devised, some of which are extremely ingenious, for separating out the typhoid bacillus from other organisms, are based upon the idea that few, if any, micro-organisms can flourish in as acid a medium as this bacillus, and no account has been taken of the refractory nature in this respect of the *B. coli communis*. This organism is, in fact, possessed of far greater powers of resistance than its more dangerous companion, and whilst the proportion of citric acid or phenol to be added, whether directly to the water or to the culture medium, is such that in some cases the other organisms present are destroyed whilst the typhoid bacillus and the *B. coli communis* are left untouched; in other methods the amount of acid prescribed is sufficient to entirely obliterate the typhoid bacillus, leaving, however, the *B. coli communis* sole master of the field. In an extremely interesting paper which has appeared in the *Zeitschrift für Hygiene*, vol. xii. p. 491, 1892 ("Ueber den Typhusbacillus und den *Bacillus coli communis*"), Dunbar discusses very fully all these points, and gives an account of the principal methods in vogue for the isolation of the typhoid bacillus, together with a critical commentary based upon his own experimental observations, as well as those of other investigators. As a result of these researches Dunbar maintains that no absolutely trustworthy method at present exists for the successful identification of the typhoid bacillus in the presence of the *B. coli communis*, and that it is highly probable that the latter has in many cases been mistaken for the former in water supposed to contain the typhoid bacillus. There can be no doubt, however, that, with a knowledge of these imperfections, the judicious application of some of these methods may very greatly facilitate the isolation of the typhoid bacillus in the presence of other organisms, and that, moreover, a method which is able to restrict the varieties present on any given gelatine plate to the *B. coli communis* and the typhoid bacillus already removes some of the chief obstacles.

A FURTHER communication from M. Moissan concerning the chemical properties of the diamond is contributed to the current number of the *Comptes Rendus*. In the first place precise determinations have been carried out of the temperatures at which various kinds of diamonds undergo combustion in pure oxygen. As the action of oxygen upon the diamond has so long been known, it appears somewhat singular that, as M. Moissan states, no exact data concerning the temperature of combustion should hitherto have been obtained. It will doubtless be remembered that Dumas and Stas, in their celebrated experiments in connection with their determination of the atomic weight of carbon, burnt diamonds in a current of oxygen in a porcelain tube heated in an ordinary earthenware table furnace. Other chemists have since performed similar experiments with the aid of the combustion furnaces employed in organic analysis. In order to be able to determine the temperature of such combustion with precision, M. Moissan has employed a modification of Le Chatelier's thermo-electric apparatus, placed along with the diamond in a wide porcelain tube closed at the ends with glass plates through which the combustion in oxygen could be viewed. It was found that when the temperature is slowly raised under these conditions the combustion proceeds gradually without the production of light. But if the temperature is raised 40° or 50° above the point at which this slow combustion commences, a sudden incandescence occurs, and the diamond becomes surrounded by a brilliant flame. Various deeply-coloured specimens of diamonds burnt with production of incandescence and flame at temperatures of 690°–720°, but transparent Brazilian diamonds did not attain the stage of slow combustion without incandescence till the temperature of 760°–770° was reached. A Cape diamond suffered gradual combustion at 780°–790°. Specimens of exceedingly hard boort likewise commenced to combine with oxygen at 790°, and burnt brilliantly at 840°–875°. When Cape diamonds were heated in a current of hydrogen to a temperature of 1200° they remained unchanged; but if the stones had previously been cut they frequently lost their brilliance and transparency. Dry chlorine gas was found incapable of reacting with the diamond until a temperature of 1100°–1200° was attained. Hydrofluoric acid vapour likewise only reacted at about the same high temperature. Vapour of sulphur also requires to be heated to 1000° before reacting, but in the case of black diamonds bisulphide of carbon is produced at about 900°. Metallic iron, at its melting point, combines with the diamond in a most energetic manner, and it is a point of considerable interest that crystals of graphite are deposited as the fused mass cools; hence the experiment forms a striking mode of converting the allotropic form of carbon which crystallises in the cubic system into that which crystallises in the hexagonal system. Melted platinum likewise combines with the diamond with great energy. A most curious reaction has been observed to occur between the diamond and the carbonates of potassium and sodium. When a diamond is placed in the fused carbonate contained in a platinum dish it rapidly disappears, and carbonic oxide is copiously evolved. Fused nitre or potassium chlorate, however, have not been observed to exert any action upon diamonds.

NOTES from the Marine Biological Station, Plymouth:—Recent captures include examples of the Hydroid *Myriothela phrygia*, the Opisthobranchs *Aplysia punctata* and *Oscanius membranaceus*, and the "cotton-spinner" (*Holothuria nigra*). The week has been marked by a rapid increase in the numbers of Echinoderm larvæ, especially of *Auricularia* and *Bipinnaria*, but *Plutei* are still relatively scarce. Ephyræ of *Aurelia* continue plentiful, and have grown appreciably. Among the Anthomedusæ, *Rathkea octopunctata*, *Sarsia prolifera* (without buds), and the gonozooid of *Podocoryne carnea* have been noticed; among Leptomedusæ, the *Eucopium*- and *Eucope*-stages of *Clytia Johnstoni* have made their appearance, together with *Thaumantias Forbesii* (Haeckel) and small *Obelia* medusæ. Several *Muggiæa* and a single *Pilidium* were seen on the 11th inst. The Nemertine *Amphiporus lactifloreus*, and the Anomoura *Eupagurus Prideauxii*, *Galathea dispersa* and *intermedia* have begun to breed.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*, ♂) from India, presented by Mr. G. J. Sheppard; a Leopard (*Felis pardus*) from Kismaya, East Africa, presented by Mr. J. Ross Todd; a Spotted Ichneumon (*Herpestes nepalensis*) from Nepal, presented by Lieut. Philip Egerton, R.N.; six Vulturine Guinea Fowls (*Numida vulturina*) from East Africa, presented by Mr. R. J. Macallister; a Black Tanager (*Tachyphonus melaleucus*) from South America, presented by Miss Trelawny; a Greater Sulphur-crested Cockatoo (*Cacatua* *galerita*) from Australia, presented by Miss Amy M. Dundas; three white-tailed Gnus (*Connochætes gnu*, ♂ ♀ ♀) from South Africa, deposited; a Burchell's Zebra (*Equus burchelli*, ♀), two Silver-backed Foxes (*Canis chama*), a Cape Bucephalus (*Bucephalus capensis*) from South Africa, a Salvin's Amazon (*Chrysotis salvini*) from South America, purchased; four Upland Geese (*Bernicla magellanica*) from the Falkland Islands, received in exchange; four Coypus (*Myopotamus coypus*) born in the Gardens.

OUR ASTRONOMICAL COLUMN.

Comet Holmes (1892 III.).—This comet has now become rather a difficult object, but the following ephemeris may be useful for those employing large instruments:—

12h. Paris Mean Time.

1893.	R.A. (app.)			Decl. (app.)		
	h.	m.	s	°	′	″
March 16.........	2	55	29·0	+ 35	27	53

The Sizes of Jupiter's Satellites.—M. J. J. Landerer describes in the *Comptes Rendus* some experiments made to test the accuracy attainable in measuring the diameters of satellites by their shadows cast on the primary. He took a finely-ground glass plate and blackened it, leaving a space in the middle representing the appearance of Jupiter with its bands and small black spots representing shadows. He then placed it at a distance of 314 m., illuminated it by a suitable light from behind, and sketched the disc through the telescope used for the actual observations. With some practice it was found possible to draw such spots correctly to within one-tenth per cent. M. Landerer then applied his method to the satellites themselves, and found the following numbers for their radii:—0·0199, 0·0184, 0·0435, and 0·0419. The number of observations was twenty-six for the first satellite, seventeen for the second, thirty for the third, and twenty-two for the fourth. The commonly accepted numbers, obtained by micrometric measurements of the bright satellites, are 0·0291, 0·0259, 0·0431, and 0·0367.

Observations of the Zodiacal Light.—In No. 3155 of the *Astronomischen Nachrichten* Mr. Arthur Searle gives an account of the experimental work he and Prof. Bailey have been carrying on with respect to the best methods of making and recording observations of the zodiacal light. Owing to the prevalent use of electric light in the neighbourhood of Harvard College Observatory, the observations were made at some distance away. The general mode of defining the position of the zodiacal light up to the present has been by drawing its outline on a star atlas exactly as it appeared in the sky at the time of observation. The great drawback about this method is that in the majority of cases the zodiacal light has no definite outline, but gradually decreases in brightness as one recedes from the axis of the figure, eventually fading imperceptibly away. That this is so is the general idea and is backed up by observations, but it is also true that the contour, so to speak, of the luminous figure is sometimes sharper at some places than at others. Instead of outline drawings these observers have substituted contour lines in which the degree of light represented by each contour is stated; the latter is accomplished by selecting a portion of the sky "unaffected by the zodiacal light, but of equal brightness with those portions traversed by the contour line." This region would naturally lie near the Milky Way and its situation is defined by the stars in the vicinity. To complete the record the geographical position of the observer's station and the time of observation should be included in the statement. In addition to the contour lines two other suggestions are put forward, (1) that the axis of brightness should be indicated by a line, and (2) that should there be distinctly observed by any chance two cones of light, an outer and an inner, such a distinction should be shown in the record by drawing a boundary between them.

Weinek's Lunar Enlargements.—Since the appearance of the magnificent enlargements obtained by Dr. Weinek from the Lick Observatory negatives, many details of surface structure have been brought to light which have up till now evaded even the aided eye. These details, consisting as they do of winding rills, valleys, and hair-like markings, appear quite sharp and distinct in contrast with the larger surface features, and it is this fact that has caused some uncertainty about their being actual features on the lunar surface. Every one acquainted a little with photography knows that a photograph loses in sharpness the more it is enlarged, and it is here very curious to find a picture after being twenty times enlarged with minute details quite crisp and sharp, and the larger portions quite fluffy, as is the case in the enlargement of Vendelinus, taken on August 31, 1890. As Mr. Elger remarks (*Observatory*, March), "if these curious markings represent actual features on the moon's surface, ought they not to be easily seen in any good telescope that shows the formation and its principal details with far greater sharpness than the twenty-times enlarged negative, and many small craters, &c., in addition which are scarcely traceable upon it? One does not understand why this should not be so, unless these objects make an impression on the sensitive plate that they fail to do on the retina, which is hardly likely to be the case." M. Faye, in *Comptes Rendus* (No. 9) for March, when referring to these enlargements, says that several members, MM. Fizeau, Mascart, and Cornu included, reserved their opinions on the interpretation of these markings, which seemed to be the results of retouching. "Certain vermiculées appearances," says he, "show a clearness which is strictly in contradiction with the very general 'estompée' appearance of the lunar cliché."

"L'Astronomie" for March—The March number of this magazine commences with some observations of Jupiter made at the observatories in Juvisy, Bruxelles, and in Spain during the past year. The numerous drawings which accompany the observations impress one with the incessant change that is taking place in the dense atmosphere, while the large red spot was as usual seen ploughing its way apparently through one of the dark belts. The period of rotation of this spot seems to have suffered a retardation during the last twelve months, as will be seen from the following table, which we take the liberty of producing here:—

	h.	m.	s.		h.	m.	s.
1879 ...	9	55	35·7	1886 ...	9	55	40·1
80 ...			35·0	87 ...			40·1
81 ...			36·1	88 ...			40·2
82 ...			37·2	89 ...			40·3
83 ...			38·1	90 ...			41·5
84 ...			39·2	91 ...			42·2
85 ...			40·1	92 ...			39·3

M. Guillaume, of the Lyons Observatory, contributes some interesting notes on the appearances of Saturn's rings during the same year, at which time it will be remembered we were lying nearly in its plane. Besides the drawings showing the general features of the planet, there are some illustrating the different degrees of luminosity observed at various parts of the ring itself. "The Circulation of Winds at the Surface of the Globe" is the title of an article by M. A. Duponchel, in which he gives as an introduction a brief historical account of the early hypotheses; while M. Flammarion gives us the fifth chapter on "Comment Arrivera la fin du Monde," dwelling for the most part on the destructive forces at work on the earth's surface.

Bermerside Observatory.—In the advertising sheets of the *Observatory* for March we are sorry to see the following notice:—"On sale (the owner giving up astronomical work) the 3-foot Common reflector, with or without dome, complete, in perfect order. Mirror by Sir H. Grubb. Full particulars on application to J. Gledhill, Bermerside Observatory, Halifax."

GEOGRAPHICAL NOTES.

A telegram from Port Stanley announces the return of the Dundee whaling ships to the Falkland Islands (see Nature, p. 282) on their way home. In the two months during which they were absent it is improbable that high latitudes were reached, but it is evident that a cargo was rapidly obtained, although it is not reported whether the species of whale hoped for was found.

The Geographical Studentship at Oxford lately held by Mr. Grundy has been awarded to Mr. W. H. Cozens-Hardy, New

College. Mr. Cozens-Hardy has already made some interesting journeys in Montenegro and the neighbouring little-known parts of the west coast of the Balkan Peninsula which he intends to study further.

THE expedition of M. Delcommune by Lake Tanganyika appears to have been the most successful of all those sent out by the Katanga Company, as its leader has returned to Leopoldville, and will soon reach Europe to recount his experiences. The expeditions of Captain Stairs and Captain Bia, although successful in reaching their destination, were unfortunate in losing their leaders, and all the parties suffered terribly from sickness and famine. One of the interesting circumstances of these expeditions is the fact that a bronze tablet commemorating the death of Livingstone has been fixed to the tree at Old Chitambo's, where the great traveller died. This tablet was sent out in duplicate by Mr. A. L. Bruce of Edinburgh, son-in-law of Dr. Livingstone, through Mr. Arnot, who being unable to reach Chitambo's himself, entrusted one of the tablets to Captain Bia, by whose party it was placed in position.

MR. MACKINDER'S educational lectures, of which the eighth was delivered in the hall of the University of London on Friday night, continue to be well attended. The subject of the lecture was the Alps as a factor in European history, and the series of fine maps specially prepared for projection by the lantern enabled the development of the historical argument to be followed from point to point.

THE March number of the *Scottish Geographical Magazine* contains a valuable note by Prof. Mohn on the climate of Greenland, in which he epitomises his discussion of Dr. Nansen's results, published in a recent Ergänzungsheft of *Petermann's Mitteilungen*, and corrects it by the record of Peary's work. The isotherms (reduced to sea-level) run parallel to the coast, the interior being coldest at all seasons; 30° F. compared with 26° on the coast for January, 30° as compared with 50° for July, and on the average for the year the centre of the land is probably about −10°, while the coast has the temperature of 30°.

THE CHATHAM ISLANDS AND AN ANTARCTIC CONTINENT.

AT the last meeting of the Royal Geographical Society Mr. H. O. Forbes discussed the question of the former extension of an Antarctic continent in relation to certain observations made during a recent visit to the Chatham Islands. The whole surface of these islands, especially Wharekauri and Rangiauria, is covered with a bed of peat in places over forty feet in depth—deeper in the northern part than in the southern—traversable in safety only by those acquainted with the country; for to the inexperienced eye there seems in most places no difference in the surface which can carry with safety both horse and rider, and that on which the lightest-footed pedestrian cannot venture without being engulfed. The surface of some of the larger and wetter depressions in the ground was covered with a brilliant-coloured carpet of luxuriant mosses, emitting an aromatic fragrance, spread out in artless undesigned parterres of rich commingled green, yellow, and purple, and endless shades of these, warning the traveller of the existence of dangerous bogs beneath, and brightening miles of treeless moorland, which, but for those floating gardens, would be uninviting and uninteresting. In many places all over the island this great peat-moss is on fire, and has for years been smouldering underground, or burning in the exposed faces of the great pits which have now been burnt out. Dr. Dieffenbach mentions these fires at his visit in 1840, and states that the combustion had begun before 1834. They appear to have been burning in one part or another of the island ever since Dieffenbach's visit. A peculiarity in the main island that strikes the visitor very early is the occurrence of many lakes and tarns. These lakes are, for the most part, on the eastern side, at the back of the low hills facing Petre Bay. The largest is fifteen miles long, over forty miles in circumference, and about ten and a half miles broad at its widest part.

Mr. Forbes's object in visiting the islands was to look for the remains of a fossil bird, fragments of which had been sent to him in New Zealand. These he discovered in considerable numbers, and found that the bird was no other than a species of *Aphanapteryx*, a large and remarkable member of the rail family, which lived contemporary with the celebrated dodo in the Island of Mauritius, and was very similar to one of the extinct flightless birds of that island. Here was the only place in the world where it was known to exist, and where it had with the dodo preserved its fading race down to about two hundred years ago, when both of them passed away and perished for ever from among living things. In the Chatham Islands the remains of the *Aphanapteryx* were found in kitchen middens of the Morioris, showing that in this region of the world also it had survived down to comparatively recent date, just as the moa had in New Zealand.

In the Chatham Islands there still live several types of flightless birds scarcely represented elsewhere, except in widely separated oceanic islands. To account for their distribution it is necessary to reason backwards to former distributions of land and sea. The occurrence of similar forms in the three southern continents and in the islands which lie between them is most easily explained by a former Austral continent of considerable northern extension. The outlines of this continent it is of course impossible to trace with anything approaching to accuracy till we are in possession of a larger number of soundings. But it is not unlikely that the great meridional masses of land—or world ridges—which are probably of primeval antiquity extended to meet prolongations northward of the Antarctic continent. There is some evidence that the direct union of South Africa with the other continents was not for so prolonged a period as the others. The presence of the *Aphanapteryx* and other ocydromine birds both in the Mascarene and in the New Zealand continental Islands supports other evidence pointing to an extension of that area south by Marion and Kerguelen Islands, and of New Zealand south, or of the Antarctic land north, by way of the Macquarrie, Auckland, and Antipodes Islands. It is interesting to observe that the great Pacific trough to the east of the longitude of New Zealand extends far south into the Antarctic region.

It is not necessary to suppose that all the southerly extending arms were connected contemporaneously with an Antarctic continent. It is impossible to account for the presence, for instance, of some South American forms in Australia and not in New Zealand; of Mascarene forms in the New Zealand region and not in Australia, or in Africa, or elsewhere, while we are unacquainted with the orography, the rivers and mountain barriers, of the submerged southern continent; and its various commissures may have been open at one time and closed at another. As there are, moreover, abundant evidences of great volcanic action over all the region, in New Zealand, South America, Mascarenia, and the Antarctic Islands, the permutations and combinations of the ups and downs of these lands, the openings and closings of the gates, paths, or stepping-stones, are beyond our computation.

The deductions as to an Antarctic continent, made on biological grounds, are supported by the depth of the circumpolar sea, so far as it is known. The submarine plateau of the Austral land slopes northward all round the shores of the known lands more gently than is the case along any other coast, and this would seem to indicate that, if elevated, the land would form in great extent a continuation of the three primal ridges of the globe southward, coalesced and spread out round the Pole, with, between these arms, the terminations of the great and permanent ocean troughs. How far these hypotheses—which are but a re-statement, in great measure, of the investigations and conclusions of many distinguished naturalists, geologists, and geographers may be substantiated or refuted by future discoveries it is difficult to say; but the discovery of these interesting *Aphanapteryx* bones on the Chatham Islands must always remain an important factor in the solution of this question.

There was an animated discussion.

ARCHÆOLOGICAL WORK IN AMERICA.

IN his report, just issued, on the Peabody Museum of American Archæology and Ethnology, Prof. Putnam is able to record the results of a very exceptional amount of useful work. This is due to the fact that while the officers of the Museum have discharged their usual duties many special archæological and ethnological researches have also been carried on with a view to the collection of material for the Chicago Exhibition. Prof. Putnam says:—

> Never before has such an extensive field of anthropological research been covered in two years' time, and it is desirable to place on record what has been accomplished. In the north,

Lieutenant Peary's expedition to Greenland has brought back a valuable collection from the little known tribe of Eskimo at Whale Sound, including their summer houses of skins, their boats, sledges, weapons, implements, utensils, ornaments; full sets of garments and carvings in ivory, as well as several hundred photographs of individuals of the tribe and of scenes illustrating their daily life; also several crania, and a complete census of the tribe with a full set of anthropometrical measurements and observations. In Labrador, the Skiles expedition (upon which I obtained positions for two Harvard students, one as a naturalist and the other as astronomer) has brought back 57 of the Labrador Eskimo,—men, women, and children with all their belongings,—making an Eskimo village now on the Fair grounds in Chicago, where it will remain until the Fair is over. On the Pacific side Dr. Sheldon Jackson has made ethnological collections in Alaska, and also among the coast tribes of Siberia. Mr. Cherry has collected from the tribes of Yucon valley; and by seven other assistants a systematic collection has been made on the northwest coast, between the Columbia River and Alaska, particularly from northern Vancouver and the Queen Charlotte Islands. On the Saskatchawan Mr. Cowie has made a complete collection to illustrate the life and customs of the tribes of the valley.

Arrangements have been made with the Canadian Commissioner of Indian affairs by which the interior tribes of Canada will be represented living on the Fair grounds; and by the cooperation of the Canadian Government World's Fair Commission a representation of the archæology of Canada has been secured. In the eastern portion of Canada Mr. Tisdale and Mr. Fenollosa, both Harvard students, have collected anthropological data, and much of ethnological importance. Nearly all the Indian tribes of the United States have been visited by students from Harvard and other universities for the purpose of obtaining anthropological data relating to the physical characteristic of the various tribes and of collecting ethnological material. . . .

The State of New York through its World's Fair Commission has also been brought into this work. The Commissioners are earnestly cooperating with me in securing a large archæological collection, and also a thorough representation of the Iroquis tribes. Families from these tribes will be living on the Exposition grounds in bark houses such as were in use when this powerful nation first came in contact with our race.

South of the United States, the Bureau of Latin-American Republics in connection with the State Department has been working with the Ethnological Department of the Exposition, of which its forms a section, and a number of officers of the army and navy were detailed to visit the various republics and arouse an interest in the Exposition, and also to make collections in ethnology and archæology under instructions which I furnished for their guidance. These gentlemen have accomplished much ethnological importance, and have secured several collections from the native peoples of Central and South America. Mr. Frederic Ober was sent to the West Indies and made a special research among the Caribs.

In relation to Mexican archæology, Mrs. Zelia Nuttal, acting in her double capacity as honorary assistant in the Museum and in the Ethnological Department of the Exposition, has been engaged in a search for objects in Europe, brought there at the time of the Spanish conquest, and has found several interesting things, connected with the period of Cortez, of which she has had facsimiles made both for the Exposition and for the Museum.

Further South in Mexico, Consul E. H. Thompson has continued the work in connection with his explorations for the Museum among the ancient ruins of Yucatan. During this time he has made about 10,000 square feet of moulds of portions of the ruined buildings, showing the façades, parts of corners of structures, doorways, and the great recess with its pointed arch of the so-named "House of the Governor" at Uxmal. He has also moulded both sides of the famous Portal at Labna. Casts are to be made from these moulds in Chicago, and there will be seen on the Exposition grounds facsimiles of these elaborately carved stone structures of Yucatan, over and around which will be the tropical plants native to the region of the ruins. As this work by Mr. Thompson was in connection with his explorations for the museum, we can secure such casts from the moulds as we may desire at the cost of making the casts, which, however, will be several thousand dollars.

The Museum Expedition to Honduras, which is an important part of the work of the year, will be specially mentioned further on, but as it forms a link in the chain of explorations it is referred to in this geographical review. Farther south, Mr. G. A. Dorsey, a graduate student in this department of the University, working as a special assistant for the Exposition, has made extensive and important explorations on the Island of La Plata, Ecuador, and in Peru and Bolivia, where he collected a large amount of material. Lieutenants Safford and Welles have secured series of garments, weapons, and other objects illustrating the tribes of portions of the interior of South America. Other officers sent out by the Latin-American Bureau have been farther south, and Patagonia and Tierra del Fuego have been drawn upon for representations of their ethnology.

Returning to the United States, archæological work has been carried on in Ohio by Dr. Metz, Mr. Saville, Mr. Moorhead, Mr. H. I. Smith and Mr. Allan Cook. In the Delaware valley, Mr. Ernest Volk, who in previous years was in the field with me, has been engaged in making a careful exploration of several ancient village sites, burial places, and workshops or quarries, where stone implements were made. Mr. Allan Cook of the University also made a brief study of a small burial-place on Cape Cod. Mr. M. H. Saville, a student assistant in the Museum, examined an ancient soapstone quarry in Connecticut from which interesting specimens were obtained both for the Museum and Exposition; and several gentlemen, particularly Dr. F. H. Williams, Mr. Wm. C. Richards and Mr. James Shepard, who showed him much courtesy, gave to the Museum a number of stone implements found on and near the old quarry. In Maine, Mr. C. C. Willoughby working entirely for the Museum, explored two singular burial-places in the Androscoggin valley in which the graves were so old that the skeletons had entirely disappeared, leaving in the graves only masses of red ochre and numerous implements and other objects of stone. This exploration was conducted in a careful manner and the notes, drawings, and photographs of the objects in place show how thoroughly the work was done. A fine lot of implements in perfect condition was found by Mr. Willoughby, and several others obtained in former years from the same place were given to the Museum by Mr. Elijah Emerson of Bucksport. This remarkable collection will be exhibited in Chicago as part of the Peabody Museum exhibit and will afterwards be arranged in the Museum. At the request of Mr. T. H. B. Pierce of Dexter, Me., Mr. Willoughby also made a partial examination of a mound near Dexter which may be a burial mound. Further exploration should be made, for if it prove to be a burial mound it would be the only one known in New England.

Important researches in physical anthropology have also been carried on. These were in part based on the observations made by the assistants among the native tribes, and in part upon collections. In this connection Dr. Franz Boas, aided by Dr. G. M. West and two clerical assistants, has been engaged in the museum in classifying the anthropological data and in preparing charts, tables, and diagrams to illustrate this subject at the Exposition. Thus for the first time there is being prepared a presentation of the physical characteristics of the native American peoples. Measurements have also been taken, and observations made, on more than fifty thousand children in the public schools in different parts of the United States and Canada, as well as on those in the Indian schools, and on many negro children. In this connection we have secured the cooperation of the authorities of the Japanese schools, and of those of the Hawaiian Islands. We shall thus have the measurements of a number of Japanese and Kanaka children for comparison. To this series of physical measurements has been added a series of tests relating to the mental development of children. These observations and deductions will not only furnish data of importance to educators, but there is reason to believe, from what has already been accomplished in this direction, that they will also give the basis upon which decided reforms in certain directions will be established. It is almost needless to say that the details of this part of the work are entrusted to Dr. Franz Boas, who is my earnest collaborator in connection with the Exposition.

This brief review of the work of about 100 assistants shows how much has been done during the year; and as the Peabody Museum is the place from which it has all been directed, and as much of the work has been done by my regular assistants and students, it is eminently proper to refer to it in this report as showing the relation of the Museum to anthropological research in America. It must also be remembered that the directors of the World's Columbian Exposition have not only given to me this grand opportunity for research, but that it has been largely paid for by the funds subscribed by the citizens of Chicago. Never before has there been a year when so much money has been expended for pure research in anthropology under one direction as during the past year; and praise and honour are due to the business men forming the directory of the Exposition in Chicago, who have so cordially met my proposals and furnished the means for carrying them out on so grand a scale. Notwithstanding the vast material interests involved in the Columbian Exposition, it must be admitted that Chicago has nobly supported pure science in this connection and has shown an appreciation of its high aims.

On the Honduras Expedition Prof. Putnam reports as follows:—

It was stated in the last report that an expedition had just started to make the preliminary explorations for the ancient ruins of Copan, and in that report is given a brief outline of the origin and plans of this undertaking on the part of the Museum to be carried on by the assistance of patrons of archæological research. It is indeed a pleasurable duty to announce that the first season's work of the expedition has proved a decided success; and that although the party had many trials and difficulties to overcome, no serious accidents or sickness occurred. Messrs. Saville and Owens returned in safety, in May last, bringing with them a large number of most interesting and important objects illustrating the wonderful carvings in stone; several vessels and many fragments of pottery; numerous ornaments made of stone, shells and bone; stone implements; and portions of human skeletons. Among the latter are several incisor teeth, each of which contains a small piece of green stone, presumbly jadeite, set in a cavity drilled on the front surface of the tooth. We had before received from very ancient graves in Yucatan human teeth filed in a peculiar manner, and now we have teeth from the ancient graves in Copan ornamented in another way. This is of particular interest in adding one more to the several facts pointing to Asiatic arts and customs as the origin of those of the early peoples of Central America. A most striking resemblance to Asiatic art is noticed in several of the heads carved in stone,—one in particular, if seen in any collection and not labelled as to its origin, would probably pass almost unchallenged as from Southern Asia. These may prove to be simply coincidences of expression of peoples of corresponding mental development brought about by corresponding natural surroundings and conditions. At present we must admit that there are many resemblances in architecture, sculpture, ornament, and religious symbolism, between Central America and portions of Asia. The true meaning of these resemblances will be made known as authentic materials for study are obtained by such thorough and exhaustive field work as the Museum has been carrying on; and none is so important for this special subject as that of the Honduras expedition. For this work, however, a large sum of money is required. The ten years allowed for the work in Honduras by the edict of that government must be utilised to the fullest extent; and each year must find the Museum ready to put its party in the field well equipped and provided with money for the very expensive work to be performed.

It is not my intention to give an abstract of the results of last year's explorations at Copan. It is far better that the report should be carefully prepared by those engaged in the actual field work from year to year. After sufficient information has been obtained about the ruins themselves, and the architectural and chronological relationship of the various structures; and after a thorough knowledge of the different modes of burial has been acquired, and all possible objects have been collected, then conclusions can be drawn which will be of scientific value, since they will be based on a thorough knowledge of all the facts. An important beginning was made by the expedition last year, plans of the plaza and of the principal structures forming the great mass of the ruins having been made, many photographs taken, and paper moulds of important sculptures, lines of hieroglyphs and several of the large idols or carved monoliths secured. Considering the difficulties of transportation (wholly by mules to the coast—a seven days' journey), both Messrs. Saville and Owens, and all associated with them must be congratulated on what they accomplished. Since the return of the expedition the photographs have been printed, preliminary reports have been prepared, and casts have been made from the moulds. These casts are now being placed in the Museum, and a series has also been made for the Boston Art Museum, and another for the Columbian Exposition.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—Prof. Liveing announces a course of demonstrations in spectroscopic chemistry, to be given during the first three weeks of the Easter term, daily (except on Saturdays) at 11, beginning on April 24.

The examination in Sanitary Science for the Diploma in Public Health will be held from April 4 to April 8.

The honorary degree of Doctor in Science will be conferred on Prof. Virchow, at a special congregation on Tuesday, March 21.

A grant of £65 has been made from the Worts Travelling Scholars' Fund to H. Woods, of St. John's College, for the purpose of palæontological research in Saxony and Bohemia.

Lawrence Crawford, B.A., Fifth Wrangler, 1890, has been elected to a Fellowship at King's College.

SOCIETIES AND ACADEMIES.

London.

Royal Society, February 16.—"The Value of the Mechanical Equivalent of Heat, deduced from some Experiments performed with the view of establishing the Relation between the Electrical and Mechanical Units, together with an Investigation into the Capacity for Heat of Water at different Temperatures." By E. H. Griffiths, M.A., Assistant Lecturer, Sidney Sussex College, Cambridge, assisted by G. M. Clark, B.A., Sidney Sussex College, Cambridge. Communicated by R. T. Glazebrook, F.R.S.

If a calorimeter is suspended in a chamber, the walls of which are maintained at a constant temperature, we can, by observations over a *small* range across that outside temperature, deduce the rate of rise due to the mechanical work done in the calorimeter, when the supply of heat is derived from stirring only. By repeating the observations in a similar manner over ranges whose mean temperature θ_1 differs from that of the surrounding walls θ_0, we obtain the change in temperature due to the combined effects of the stirring, radiation, conduction, and convection at all points of our whole range of temperature. As the success of the method depends (1) on the possibility of maintaining the exterior temperature unchanged, and (2) on the regularity of the supply of heat due to the stirring, we briefly indicate our method of securing those conditions.

1. The calorimeter[1] was suspended within an air-tight steel chamber. The walls and floor of this chamber were double, and the space between them filled with mercury. The whole structure was placed in a tank containing about 20 gallons of water, and was supported in such a manner that there were about 3 inches of water both above and beneath it. The mercury was connected by a tube with a gas regulator of a novel form, which controlled the supply of gas to a large number of jets. Above those jets was placed a flat silver tube, through which tap water was continually flowing into the tank, all parts of which were maintained at an equal temperature by the rapid rotation of a large screw. Thus, the calorimeter may be regarded as suspended within a chamber placed in the bulb of a huge thermometer—the mercury in that bulb weighing 70 lbs. A change of 1° C. in the temperature of the tank water caused the mercury in the tubes of the regulating apparatus to rise about 300 mm. Special arrangements were made by which it was possible to set the apparatus so that the walls surrounding the calorimeter could be maintained for any length of time at any required temperature, from that of the tap water (in summer about 13° C. in winter 3° C.) up to 40° C. or 50° C. We know by observation that the temperature of the steel chamber (when once adjusted) did not vary by 1/500° C., and we believe the variations were much less.

2. We experienced great difficulty in devising a suitable form of stirrer; and we attribute the failure of our earlier experiments to defects in the ordinary forms. We find it impossible, without a lengthy description, to give a clear idea of the stirrer ultimately adopted. We can only state here that it was completely immersed when the depth of the water exceeded 1 cm., that

---

[1] The calorimeter was of cylindrical form, and suspended by three glass tubes. It was made of "gilding metal," which both internally and externally was covered with a considerable thickness of gold. All metal surfaces within the calorimeter were thickly gilded.

its bearings were outside the steel chamber, and that the water was thrown from the bottom to the lid of the calorimeter.

More than 100 experiments were performed (many of them lasting several hours) in order to determine the value of $\sigma + \rho(\theta_1 - \theta_0)$,[1] when the calorimeter contained different masses of water. The harmony amongst the results was satisfactory.

The pressure in the space between the calorimeter and the walls of the steel chamber was reduced, as a rule, to between 0·3 and 1·0 mm.[2]

The absolute value of the loss by radiation, &c., at different pressures was ascertained, and it was found that the rate of gain or loss decreased very rapidly when the pressure was reduced below 0·5 mm.

If $\left(\frac{\delta\theta_1}{\delta t}\right)_{\sigma,\rho}$ is the rate of rise due to the non-electrical supply, and $\left(\frac{\delta\theta_1}{\delta t}\right)$ that due to the electrical supply, then

$$\frac{\delta\theta_1}{\delta t} = \left(\frac{\delta\theta_1}{\delta t}\right)_e + \left(\frac{\delta\theta_1}{\delta t}\right)_{\sigma,\rho} \quad \dots\dots (1)$$

We have indicated the manner in which we determined the last term of this equation, and thus, by direct observation of $\frac{\delta\theta_1}{\delta t}$, we were able to obtain the value of $\left(\frac{\delta\theta_1}{\delta t}\right)_e$ and

$$\left(\frac{\delta\theta_1}{\delta t}\right)_e = \frac{E^2}{J.R'.M'} \quad \dots\dots\dots (2)$$

where R′ is the resistance of the coil, and M′ the capacity for heat of the calorimeter and its contents at a temperature θ_1.

Throughout the experiments E was kept constant, the arrangement for maintaining the ends of the coil at a constant potential difference worked admirably, and it is probable that in no case did the variations exceed 1/10,000 of the mean potential difference during each experiment.

The value of R was determined by a direct comparison (conducted by Mr. Glazebrook) with the B. A. standards and values of R were expressed in true ohms as defined in the B. A. Report, 1892.

The difference between the temperature of the coil and that of the surrounding water was ascertained, and the resulting difference of resistance was found to be such that $\delta R = \cdot 00422 n^2$, where n was the number of Clark cells by which the potential difference at the end of the coil was maintained.

The mercury thermometers were standardised by direct comparison with several platinum thermometers, and a further comparison has (through the kindness of Dr. Guillaume) been made with the Paris hydrogen standard. The difference obtained by the two methods in the value of the range is only ·005° C.

The various quantities in equation (2) having been determined (with the exception of J and M′), we can deduce from equation (2) the time (T) of rising 1° C at any point of our range when R = 1ω and E is the potential difference of one Clark cell at 15° C.

We thus get

$$\frac{J}{E^2} M' = T \quad \dots\dots\dots\dots (3)$$

If w be the weight of water, and w_x the water equivalent of the calorimeter at the standard temperature, and if f and g be the temperature coefficients of their specific heats, then

$$M' = w(1 + f\overline{\theta_1 - \theta}) + w_x(1 + g\overline{\theta_1 - \theta});$$

hence

$$\frac{J}{E^2}\{w(1 + f\overline{\theta_1 - \theta}) + w_x(1 + g\overline{\theta_1 - \theta})\} = T \quad . . (4)$$

By repeating observations with different weights of water, w_1 and w_2, and observing T_1 and T_2, the corresponding times, we obtain by subtraction

$$\frac{J}{E^2}(w_2 - w_1)(1 + f\overline{\theta_1 - \theta}) = T_1 - T_2 \quad . . . (5)$$

Hence when $\theta_1 = \theta$ (*i.e.* at the standard temperature) we can find J without first ascertaining the values of f, g, or the water equivalent of the calorimeter, and by repeating the observations over different ranges we can find f without previously obtaining J; or, having obtained f, we can find w_x and g, and then by equation (4) deduce the value of J from a single experiment. We have adopted both methods as a check upon the calculations, which involve much arithmetic. The latter method is the more convenient, as it enables us to ascertain the results of separate experiments, but it cannot be applied until the values of f, g, and w_x have previously been obtained by observations on two different weights at two different temperatures.

We give the values of T at 15°, 20°, and 25° C.

TABLE XLI.—VALUES OF T AT 15°, 20°, AND 25° C.

Temp.	Series I.		Series II.		
	Group B. $w = 188\cdot065$.	Group E. $w = 277\cdot931$.	Group A. $w = 139\cdot776$.	Group C. $w = 199\cdot674$.	Group D. $w = 259\cdot500$.
15·000	557·14	740·46	458·87	580·95	702·91
20	557·62	740·60	459·35	581·25	703·05
25	558·09	740·75	459·81	581·55	703·20
No of col. } 1	2	3	4	5	6

From this table we obtain the following results:—

Specific heat of water at 25° in terms of water at 15°, deduced from columns 4 and 6 . . . . = 0·99734
Ditto from columns 4 and 5 . . . . = 0·99722
Ditto from columns 5 and 6 . . . . = 0·99746
Mean . . . . . . = 0·99734

Hence, adopting 15° C. as the standard temperature, the

SPECIFIC HEAT OF WATER = 1 − 0·000266 $(t - 15)$.[1]

Also by means of equation (15) we get the following values of J:—

Columns 4 and 6 ... ... J = 4·1939 × 10⁷
" 4 " 5 ... ... J = 4·1940 × 10⁷
" 5 " 6 ... ... J = 4·1940 × 10⁷
Mean ... ... J = 4·1940 × 10⁷

This value of J, as previously pointed out (equation 5), is entirely *independent of the value assigned to the water equivalent of the calorimeter.*

And we find the water equivalent of the calorimeter at 15° C. in terms of water at 15° C. = 85·340 grams. The water equivalent of the calorimeter at 25° C. in terms of water at 15° C. = 86·174 grams.

Hence water equivalent = 85·340{1 + 0·000977$(t - 15)$}.

We can now find the capacity for heat of the calorimeter and contents for any weight of water at 15°, 20°, and 25° C., and deduce the value of J from each group separately.

TABLE XLIII.—VALUES OF J.

Group.	15°	20°	25°	Mean.
A	4·1940 × 10⁷	4·1940 × 10⁷	4·1939 × 10⁷	4·1940
B	4·1930 "	4·1941 "	4·1949 "	4·1940
C	4·1939 "	4·1938 "	4·1937 "	3·1938
D	4·1940 "	4·1939 "	4·1940 "	4·1940
E	4·1938 "	4·1940 "	4·1943 "	4·1940
				4·1940

We have in the above table given the values resulting from the calculation at different temperatures, for the limit of our experimental errors is thus clearly indicated, since the values of

---

[1] σ = rise in temperature per 1 second due to the stirring. ρ = gain or loss in temperature per 1 second due to radiation, &c., when $\theta_1 - \theta_0 = 1°$ C.

[2] The pressures were ascertained by a McLeod's gauge.

[1] Over the range 14° to 26° C.

J ought (in the absence of experimental errors) to be identical at all temperatures. The close agreement between the values from different groups, and from the same group at different temperatures, is a satisfactory proof of the accuracy of our determination of the water equivalents of the calorimeter, and of the changes in it and in the capacity for heat of the water.

Hence, if we assume

1. The unit of resistance as defined in the "B.A. Report," 1892;
2. That the E.M.F. of the Cavendish Standard Clark cell at 15° C. = 1·4342 volts;[1]
3. That the thermal unit = quantity of heat required to raise 1 gram of water through 1° C. at 15° C.,

the most probable value of

$$J = 4{\cdot}1940 \times 10^{7}.^{2}$$

This, by reduction, gives the following:—

$J = 427{\cdot}45$ kilogramme-metres in latitude of Greenwich ($g = 981{\cdot}17$).

$J = 1402{\cdot}2$ foot-pounds per thermal unit C in latitude of Greenwich ($g = 32{\cdot}195$).

$J = 778{\cdot}99$ foot-pounds per thermal unit F in latitude of Greenwich ($g = 32{\cdot}195$).

The length of this abstract is already unduly great, and we will, therefore, not enter on any discussion of the results beyond remarking that if we express Rowland's value of J in terms of our thermal unit we exceed his value by 1 part in 930, and we exceed the mean of Joule's determination by 1 part in 350.[3]

The difference between Rowland's value of the temperature coefficient of the specific heat of water and ours would, however, cause both his and our values of J to be identical if expressed in terms of a thermal unit at 11·5° C.

March 2.—"The Effects of Mechanical Stress on the Electrical Resistance of Metals." By James H. Gray, M.A., B.Sc., and James B. Henderson, B.Sc., International Exhibition Scholars, Glasgow University. Communicated by Lord Kelvin, P.R.S.

This investigation was begun for the purpose of obtaining an easily worked method of testing the effect of any mechanical treatment on the density and specific resistance of metals.

For alteration of density, copper, lead, and manganese copper wires were tested. The effect of stretching was always to diminish the density, the alteration being small however: for copper about $\frac{1}{2}$ per cent., and for lead $\frac{4}{5}$ per cent. The effect of drawing through holes in a steel plate was somewhat greater, showing at first an increase of 2 per cent.; and, when the drawing was continued, the density began to diminish till, after drawing from diameter 2 mm. to 1·3 mm., it showed an increase on its original value of $\frac{9}{10}$ per cent. Several other interesting results on alteration of density were obtained.

The most important part of the investigation, however, relates to the alteration of specific resistance of copper, iron, and steel wire due to stretching; and, in connection with this, the authors wish particularly to emphasise the advantages to be gained from using the unit of specific resistance introduced by Weber, who always defined it in weight measure, that is, as the resistance of a length of the metal numerically equal to its density and section unity.

The conclusions arrived at are that for practical purposes any mechanical treatment, however severe, does not affect the electrical properties of the metals tested. As contrasted with this, it is interesting to note that the smallest impurity in the metal produces a greater change than the most severe mechanical treatment. For example, an impurity of $\frac{2}{5}$ per cent. lowers the electrical conductivity by 13·5 per cent., while an impurity of $\frac{4}{5}$ per cent. lowers it as much as 30 per cent.

"A New Hypothesis concerning Vision." By John Berry Haycraft, M.D., D.Sc. Communicated by E. A. Schäfer, F.R.S.

The author pointed out that when a blue pigment is mixed with its complementary pigment—orange-yellow—it makes a grey, not a green as is generally stated. This can be shown by the use of transparent colours, such as watery solutions of the aniline dyes. When you mix an opaque oil blue with its complementary orange-yellew and get a green it is because the light only passes through a very thin superficial film of the mixture, and a paint which is orange-yellow in the mass is only a pale yellow in a thin film, and transmits the green spectral rays stopped by the orange-yellow. In this case, therefore, the thin film of paint which alone affects the light is not a mixture of blue and its complementary orange-yellow, but only a mixture of blue and pale yellow.

In the case of Maxwell's colour discs you get a grey if the blue and yellow are complementary, or a green or red if they are not, just as in the case of mixtures of transparent pigments. Complementary pigments are simply those which between them absorb all spectral rays; thus blue absorbs red, yellow, and some green, and the complementary orange-yellow absorbs violet, blue, and some green. A mixture of these pigments on the palette—if transparent enough—or on the Maxwell's disc absorbs, therefore, the light which falls upon it from all parts of the spectrum in about equal proportions. If examined by the spectroscope the mixture of pigments and the rotating disc both give a dim, unbroken spectrum identical with that of white paper held in half light. In our study of vision we have to deal with the stimulus—spectral rays—and the resulting sensations. Inasmuch as the stimulus—the light of a dim, unbroken spectrum—is the same whether the eye looks at a mixture of blue and orange yellow on a palette, at a Maxwell's disc, or again at a piece of white paper held in half light, the resulting sensation must in all cases be the same—we call it grey or white. In the case of the rotating Maxwell's disc experiment we are not dealing with the fusion of blue and orange-yellow sensations, but the adding together of two halves of the spectrum to make a whole one. Once understood, the physiologist will discard the experiment altogether, as it has no bearing upon colour vision.

The work of Sprengel, Darwin, and especially of Sir John Lubbock, shows that the colour sense has gradually been evolved by the coloured environment of the species. We may infer that in the ancestral condition in which light was distinguished from darkness, but blue was undistinguishable say from red, all visual stimuli were felt as white or various shades of grey. The greater the amount of spectral light the nearer the sensation approached white. This, if accepted, explains why the outer and less used parts of the retina are colour blind in the human eye at the present day, and further explains why a minimal stimulus from a coloured object gives rise to a sensation grey. Just as we may smell something, but require to "sniff," in order to make out what it is, so the coloured object held far away may give rise only to the primitive sensation grey, and has to be brought nearer in order that its colour quality can be felt.

We may explain the fact that an artificial mixture of spectral green and red gives rise to the sensation yellow by the fact that all coloured objects which send to the eye red and green rays also send the intermediate yellow; these objects give rise to the sensation yellow, and we call them by that name. Inasmuch as this association of red and green rays has in the evolution of the eye always combined with yellow rays to produce the sensation yellow, we can explain, as an instance of association, the fact that artificially combined red and green rays produce a yellow sensation.

When, say, red and blue-green spectral rays are artificially combined, they produce a grey sensation, and this we can explain by the fact that no fully coloured natural object sends to the eye such a combination, which combination, therefore, played no part in the evolution of the colour sense, and it produces merely a primitive sensation of simple brightness—white or grey.

That a coloured object brightly illuminated appears white follows the law of maximal stimulation, for in this case the object absorbs so slight a proportion of the light from any one part of the spectrum that that part gives rise to its maximal effect, and the rest of the spectrum can do no more. In this case, therefore, the eye is affected equally (maximally) by all parts of the spectrum, and we have of course the sensation of white.

The above view is an attempt to explain some of the facts of vision by showing that they are on all fours with other facts known to the physiologist. This seems to the author a more scientific method than the one adopted by Young and Helmholtz, who "conceive" a visual apparatus, and endow it with such properties as will, in their opinion, account for the facts of visual sensation.

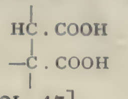
---

[1] If we assume the E.M.F. of our Clark cells to be the same as that of the Cavendish standard (and we are inclined to think we have over-estimated the difference), we get $J = 4{\cdot}1930 \times 10^{7}$.

[2] The value obtained by us in 1891 $= (4{\cdot}192 +) \times 10^{7}$.

[3] Rowland obtained the mean value of Joule's determinations by assigning values to different experiments, and the above comparison refers to the numbers thus obtained. If, however, we attach equal weight to all Joule's results, as reduced by Rowland, the mean *exceeds* our value by 1 in 4280, assuming our expression for the temperature coefficient of the specific heat of water.

Chemical Society, February 16.—Prof. A. Crum Brown, F.R.S., President, in the chair.—It was announced that the following changes in the Council were proposed by the Council for the ensuing year:—President, Prof. H. E. Armstrong, vice Prof. Crum Brown. Vice-Presidents: Dr. E. Atkinson and Mr. C. O'Sullivan, vice Prof. Hartley and Mr. Warington. Secretary, Prof. Dunstan, vice Prof. Armstrong. Ordinary Members of the Council: Messrs. C. F. Cross, Bernard Dyer, Lazarus Fletcher, and W. A. Shenstone, vice Mr. H. Bassett, Prof. Ferguson, Mr. J. Heron, and Mr. S. U. Pickering.—The following papers were read: Note on the preparation of platinous chloride, and on the interaction of chlorine and mercury, by W. A. Shenstone and C. R. Beck. The authors find that very pure specimens of chlorine may be prepared by igniting platinous chloride obtained by heating hydrogen platinichloride in a current of dry hydrogen chloride. On passing the dry gas for fifteen hours over the platinichloride at the boiling point of mercury and igniting the residue *in vacuo*, chlorine was obtained which contained 99·84 per cent. of the gas. A portion of the platinous chloride obtained in this experiment was heated at 500° in a current of dry hydrogen chloride during many hours; on then igniting the residue, chlorine was evolved which when treated with mercury only left a residue of 0·06 per cent. unabsorbed. The platinous chloride made by the above method probably contain a little platinum, but as a source of chlorine, it seems to be superior to the product of more familiar processes. The second sample of chlorine mentioned above acted very sluggishly on mercury; this fact, considered in connection with the great purity of the gas, supports the authors' view that the activity of chlorine towards mercury is probably due to the presence of impurity in the former.—The action of phosphoric anhydride on fatty acids. Part III., by F. S. Kipping. In the present paper the author shows that caprylone $(C_7H_{15})_2CO$, nonylone $(C_8H_{17})_2CO$, and myristone $(C_{13}H_{27})_2CO$, can be readily prepared from the corresponding fatty acids by the action of phosphoric anhydride; a number of derivatives of these ketones are described. Mixed ketones of the general formula R.CO.R′ are produced when a mixture of two fatty acids is treated with phosphoric anhydride at a moderately high temperature; the mixed ketone is, however, accompanied by two simple ketones. Treatment with phosphoric anhydride would seem to be one of the simplest and most rapid methods by which the ketone $(C_nH_{2n+1})_2CO$ can be prepared from a fatty acid $C_nH_{2n}O_2$.—Regularities in the melting points of certain paraffinoid compounds of similar constitution, by F. S. Kipping. The author has prepared and characterised a number of hydroximes, secondary alcohols and ethereal salts derived from the fatty ketones $(C_nH_{2n+1})_2CO$ and draws attention to certain regularities observed on comparing the melting points of these compounds. The melting points of all ketones of the general formula $C_nH_{2n}O$ cannot be calculated by means of the formula given by Mills (*Phil. Mag.* 1884), inasmuch as isomeric ketones frequently melt at different temperatures.—Some relations between constitution and physical constants in the case of benzenoid amines, by W. R. Hodgkinson and L. Limpach. A study of the formyl and acetyl derivatives of certain homologues of aniline shows, (1) that the entry of alkyl groups into the nucleus affects the melting and boiling points in a regular manner; (2) that the conversion of formyl into acetyl also involves an alteration in physical properties in extent the same as that produced by introducing CH_3 into the nucleus in an ortho- or para-position relatively to the amido-group, and (3) that the same (or any?) alkyl group entering the nucleus in the meta-positions has no effect on melting or boiling point. Several numerical regularities are also apparent.—Electrolysis of sodic ethylic camphorate, by J. Walker. On electrolysis, sodium ethyl camphorate yields the ethyl salts of two new acids, viz. campholytic acid, $C_8H_{13}\,.\,COOH$, and camphotetic acid, $C_{16}H_{28}(COOH)_2$. The first of these is a monabasic, unsaturated acid boiling at 240 – 242°. It is lævo-rotatory, but gives a dextro-rotatory ethyl salt. Camphotetic acid is a colourless crystalline solid, melting at 132°; it behaves as a saturated, bibasic acid and forms well-characterised salts. Judging from the nature of the electrolysis and the behaviour of campholytic acid towards bromine, camphoric acid should contain the group



$$\begin{array}{l} \quad| \\ \mathrm{HC\,.\,COOH} \\ \quad| \\ \mathrm{-C\,.\,COOH} \\ \quad| \end{array}$$

—The hydrates of hydrogen chloride, by S. U. Pickering. Determinations of the densities of aqueous solutions of hydrogen chloride show a strongly-marked break indicative of the presence of a trihydrate. The author has obtained this hydrate in the solid state by making a series of freezing-point determinations; it forms large, transparent crystals melting at – 24°·9. The densities also indicate the existence of a change of curvature at a point corresponding to a hexhydrate; the freezing-point determinations afford no evidence for or against the existence of this substance, but the presence of a decahydrate was indicated.—A new base from *Corydalis cava*, by J. A. Dobbie and A. Lauder. By exhausting crude corydaline with hot water the authors have isolated a new alkaloid of the composition $C_{19}H_{25}NO_4$, which they term corytuberine; this alkaloid contains only two methoxy-groups, whilst corydaline contains four. A number of its salts are described. The authors also give some notes on yet another alkaloid, which they consider to be distinct from all the bases of *Corydalis cava* hitherto described.

February 20.—Lord Playfair, F.R.S., Vice-President, in the chair.—This being the anniversary of the death of Hermann Kopp, Prof. T. E. Thorpe delivered a memorial lecture entitled "The Life Work of Hermann Kopp."

PARIS.

Academy of Sciences, March 6.—M. Lœwy in the chair.—On a partial differential equation, by Émile Picard.—On the spectro-photographic method which makes it possible to obtain photographs of the chromosphere, faculæ, protuberances, &c., by M. J. Janssen. This method was outlined by M. Janssen as early as 1869, at the Exeter meeting of the British Association.—Analysis of the ashes of the diamond, by M. Henri Moissan. All the specimens of the carbonado and Cape diamond analysed contained iron, as shown by the potassium sulphocyanide reaction. This metal formed the larger portion of the ashes. Silicium also occurred regularly, and calcium very frequently. It will be remembered that this alkaline earthy metal was found by M. Daubrée in native iron from Ovifak.—On some new properties of the diamond, by M. Henri Moissan (see Notes).—The pancreas and the nervous centres controlling the glycemic function, by MM. A. Chauveau and M. Kaufmann. The inhibitory action exerted by the pancreas on the glycogenic function of the liver appears to be dependent upon an excito-secretory centre controlling the cells performing the internal secretion of the pancreas. This centre is situated in the encephalic portion of the spinal cord, and the inhibitory impulse acts through this centre upon an excito-secretory centre controlling the glycogenic activity of the liver. The removal of the pancreas eliminates this control, and renders an excessive activity of the liver more serious.—The fixation of torrents and the planting of the mountains, by M. Chambrelent. It has been calculated that in the last forty years France has suffered losses amounting to 700 million francs due to inundations in places where the mountains were not wooded sufficiently to check the ravages of mountain torrents after heavy rain. The Chamber has recently voted a sum of 2,600,000 frcs. for the planting of the mountains, and it is hoped that the work will be completed in twelve or fifteen years.—On the cause of the variations of terrestrial latitude, by M. Hugo Gyldén.—On some new derivatives of phenolphtaleïn and fluoresceïn, by MM. A. Haller and A. Guyot.—On the diameters of Jupiter's satellites, by M. J. J. Landerer.—On a class of dynamical problems, by M. P. Staeckel.—On surfaces whose principal planes are equidistant from a fixed point, by M. Guichard.—On a theorem of M. Stieltjes, by M. Cahen.—On a partial differential equation of the second order, by M. J. Weingarten.—On the calculation of stability of ships, by M. É. Guyon.—On electric waves in wires, and electric force in the vicinity of a conductor, by M. Birkeland.—Oscillographs; new apparatus for the study of slow electric oscillations, by M. A. Blondel.—Photographic reproduction of gratings and micrometers engraved on glass, by M. Izarn. Ammonium bichromate in gelatine gives better results than either collodion or silver salts in gelatine. Copies of microscopic divided scales and gratings were obtained easily and with certainty, and reflection gratings were produced by employing silvered instead of plane glass.—Concerning the direct-reading stereo-collimator of M. de Place, by M. R. Arnoux.—On the industrial preparation of aluminium, by M. A. Ditte. The alkaline aluminates are decomposed by water, and even in the presence of an excess of alkali the introduction of a few crystals of aluminium hydrate into the solution suffices to prevent the establishment of equilibrium and to effect the decomposition of the aluminate, the rapidity of the reaction being increased by well stirring. In the industrial process of obtaining aluminium from bauxite, these crystals are provided by adding to the sodium aluminate a little of the deposit obtained by treating it with a current of carbon dioxide in the cold, a deposit which consists of crystallised aluminium hydrate. The gelatinous hydrate has no such effect. The alumina precipitated is very pure. Substances such as silica and phosphoric acid, dissolved out of the bauxite by the caustic soda employed, remain in solution.—On the isomerism of the amido-benzoic acids, by M. Oechsner de Coninck.—On the dimorphism of the chloroplatinate of dimethylamine, by M. Le Bel.—On inuline and two new proximate bodies—pseudo-inuline and inulenine, by M. C. Tanret.—Absorbing action of cotton on dilute solutions of sublimate, by M. Léo Vignon.—Remarkable resistance of animals of the genus *Capra* against the effects of morphine, by M. L. Guinard.—Alterations of molecular tissue in the barbel due to the presence of myxosporidia and microbes, by M. P. Thélohan.—On the maxillary apparatus of the Eunicidæ, by M. Jules Bonnier.—On the perfume of orchids, by M. Eugène Mesnard.—Experimental researches on the mole and on the treatment of this disease, by M. Julien Constantin.—A disease of the endive, by M. Prillieux; remarks by M. Arm. Gautier.—On the morphology of the cellular nucleus in the Spyrogyras and the resulting phenomena in this plant, by M. Ch. Decagny.—Discovery of *Mastodon Borsoni* at Rousillon, by M. A. Donnezan.—On the use of soluble cartridges in oceanographic measurements and experiments, by M. J. Thoulet.—Temperatures observed in the winter of 1789 at Montbéliard, by M. Contejean.

Berlin.

Physical Society, January 20.—Prof. Kundt, President, in the chair.—Dr. Haentzsch spoke on the potential equation, gave an historical account of researches bearing on it, and added a communication on the results of his own investigations. Prof. Planck explained the arrangement and principle of a truly-tuned harmonium, built on the system of C. Eitz, and bequeathed to the Physical Institute. The instrument includes four and a half octaves, and possesses special notes, arranged in several rows and distinguished by four different colours, for the fifths, the major and minor thirds, and the major and minor sixths. The pure intonation of the harmonium enables it to be used with far greater success than one which is "tempered," for demonstrating that our ear accommodates itself to concords which are not quite pure, and is influenced in its discrimination of concords by the recollection of tones heard previously. The instrument is not suited for concert purposes.

Physiological Society, February 3.—Prof. du Bois Reymond, President, in the chair.—Prof. Gad opened a discussion on the communication made by Prof. Behring at the last meeting of the Society (see Nature, vol. xlvii. p. 336). The discussion turned chiefly on the applicability of the results of Prof. Behring's experiments to the treatment of tetanus in man. Dr. Wernicke exhibited diphtheritic cultures which had been kept for more than a year, and still developed rapidly in either agar, gelatine, or broth. He then demonstrated on dissected guinea-pigs the more important symptoms of diphtheritic infection, viz. œdema at the place of inoculation, hyperæmia of the liver, kidneys, and adrenals, serous exudations in the abdomen and thorax. He next exhibited some guinea-pigs which, after inoculation with the bacilli of diphtheria, had been treated with blood-serum from other animals immune to diphtheria and had been thereby cured. It was found that the longer the interval which elapsed after inoculation before the curative serum was administered, the greater was the dose of the serum required to effect a cure. He finally reported on experiments on dogs in which immunity and recovery after inoculation had been similarly attained.

Meteorological Society, February 7.—Prof. von Bezold, President, in the chair.—Dr. Schubert gave an account of recent researches on the influence of forests on the temperature and humidity of the air, with special reference to certain forests in Austria. So far only the experiments made in Podolia in a leafy forest on level ground have led to uniformly positive results. From these it appears that the forest lowers the mean temperature of the air, but only in so far that the temperature at 8 p.m. is much lower than that existing in the open country, that at 2 p.m. it is higher than in the open, and that the daily amplitude of variation is greater in the forest. The speaker had however found, from a careful perusal of the existing data, and from comparative determinations made in the forests near Eberswalde, that the results so far obtained are markedly affected by radiation. The true temperatures of the air inside and outside the forest have not yet been measured, and for this purpose it would be necessary to use an aspiration-thermometer. Determinations of humidity are similarly adversely affected by wind and by evaporation due to air-currents. In this case accurate results would be obtained by means of an aspiration-psychrometer. Prof. Sprung communicated an observation he had made at the Potsdam meteorological institute on the recent coldest day in January. While endeavouring to find the most suitable position for a thermometer, he observed, while using similar aspiration-thermometers, the following simultaneous temperatures at four different places, viz. $-23°$, $-23°$, $-18°$, and $-17°$. The four places were: (1) in an adjoining meadow two metres above the ground; (2) at the north side of the observatory two metres above the ground; (3) two metres above the platform of the tower; and (4) at the cage of the anemometer seven metres above the platform. Hence the temperature at the comparatively slight elevation of the anemometer was 6° higher than at the ground, whereas usually the same four thermometers showed a slight fall of temperature at the greater elevation.

COLLIERS AND COLLIERY EXPLOSIONS.

Coal Pits and Pitmen. A Short History of the Coal Trade, and the Legislation affecting it. By R. Nelson Boyd, M.Inst.C.E. (London: Whittaker and Co.)

AS the author remarks in his preface, his present work is a re-cast of a book published for him in 1879 by W. H. Allen and Co., under the title of "Coal Mines' Inspection." A casual examination of both books shows that they are alike in their main features; only, the latter work has been extended so as to include some of the events of later years. The subject is divided into twelve chapters, to which are added four short appendices and a good index. The text extends to 239 pages 8vo of good readable print, and there are a few good illustrations of ancient mechanical arrangements, including the steel mill.

Mr. Boyd begins by giving a very short historical account of the situation before Parliament began to interfere in the relations between masters and men. He then describes the circumstances which led to the appointment of successive Royal Commissions, charged to inquire into various matters relating to mines and miners, and he sketches briefly the leading features of the reports presented by these Commissions, together with the chief points of interest contained in the legislative enactments which were founded upon some of them. Our author also pauses from time to time to recount in considerable detail the events of more than passing interest, such as explosions, inundations, and other accidents which happened during the period with which he is dealing; and lastly, in his appendices, he gives the titles of the Acts of Parliament affecting coal mines and miners, both English and Scotch, a list of serious colliery explosions previous to and since 1850, and a table showing the production of coal at different times, commencing in 1660, and brought down to 1891.

Among other more or less important provisions of the Acts of Parliament our author gives prominence to:—The exclusion of women from mines, the appointment of Government inspectors, the limitations of the ages at which boys can be employed, the restrictions under which explosives may be used, the requirement that each mine should have two distinct shafts, that each mine manager must have a certificate similar to that of a sea captain, that payment must be made by weight and not by measure, the conditions under which safety lamps are to be used, and the method of dealing with coal-dust when it is present.

He also reviews such questions as the payment of royalties and wayleaves to landlords, the employers' liability, the wasteful consumption of fuel, the duration of the coal supplies, and old-age pensions to miners.

Contrasting the present with the past he says:—"The workmen of the present day have attained a distinct social position, have representation in the House of Commons, and trade unions, societies, and powerful combinations," whereas formerly the Scotch colliers were *adscriptæ glebæ*, that is, were bought and sold with the land: an Act of the Scotch Parliament of 1660 prohibited them from leaving their employment without a written attestation from their masters under pain of punishment in their bodies, and any person employing them was ordered to return them within twenty-four hours or pay a fine of one hundred pounds Scots. The colliers of the North of England were little better, being hired by the year under a system of binding or bonding; those of the Bristol coal-field were described by contemporary writers as being as brutal and ignorant as savages. Colliers lived apart from the rest of the community, were looked down upon with contempt by their fellow-men, and diverted themselves with bull-baiting, drinking, and debauchery.

The state of serfdom was removed by various Acts of Parliament passed during the latter half of last century, apparently more with the object of increasing the numbers of the colliers by drawing other classes of labourers into the mines than from any specially humanitarian motives. But at length a day dawned when higher principles began to prevail. From 1842, when Lord Ashley's Act was passed for the exclusion of women from the mines, onwards to 1887, one Act was passed after another, each having the same object in view, namely, the amelioration of the lot of the miner.

The frequent occurrence of disastrous colliery explosions and the great destruction of life and property which accompanied them, had done more than anything else to draw the attention of the public to a consideration of mining affairs, and had likewise been the principal incentive to the appointment of Royal Commissions and to the passing of Acts of Parliament to regulate the supervision and the working of mines.

Notwithstanding all that had been done previously, more lives were lost in explosions during the five years ending 1870 than during any preceding five years, the aggregate number lost in fifteen explosions, each of which involved the loss of ten lives and upwards, having amounted to 923.

The Coal Mines' Regulation Act of 1872 was drawn up with great care by Mr. Bruce (now Lord Aberdare), the Home Secretary. It embraced the experience of the Inspectors of Mines, as well as the combined wisdom of mine owners, engineers, managers of mines, and delegates of the colliers. But, firedamp having been hitherto regarded as the sole cause of colliery explosions, the stringent provisions of that Act were directed exclusively towards the detection and removal of that element of danger.

In 1845 Messrs. Lyell and Faraday, who had examined the scene of the Haswell colliery explosion, which they attributed to large accumulations of firedamp in the empty spaces (goaves) from which pillars had been removed, remarked that firedamp had not been its only fuel, but that doubtless the coal-dust which was raised and swept along *by the firedamp flame* would be decomposed by the heat of that flame, and would therefore add to the force of the explosion.

Between the years 1860 and 1875 several French mining engineers were impressed with the idea that coal-dust had played a part in certain explosions which took place in France. Some experiments were made by a committee of the Société de l'Industrie Minérale, and by M.

Vital, one of the Ingénieurs des Mines, with the object of ascertaining the likelihood or otherwise of this hypothesis, but no definite conclusions were arrived at.

In December, 1875, the present writer examined into all the circumstances attending a colliery explosion in South Wales, and gave a minute description of it before a coroner's jury. He insisted that coal-dust had been the principal agent in that explosion, and that firedamp had only played a subordinate part. At the same time he referred to the results of experiments he had made which showed conclusively that when fine dry coal-dust is added to a mixture of air and firedamp, in which the firedamp is present in so small a proportion as to escape detection by the means employed for this purpose in mines, the mixture is inflammable at ordinary pressure and temperature, and when ignited burns like a jet of inflammable gas. In March, 1876, he read a paper before the Royal Society, in which he described these experiments, as well as the apparatus with which they had been carried out. In this paper, also, he claimed that when an explosion is once begun in a dry and dusty mine it becomes self-propagating, and, provided the continuity of the deposit of coal-dust is unbroken, it extends to the utmost limits of the workings. This became known afterwards as the "Coal-dust Theory of Great Colliery Explosions."

In May, 1876, Mr. Hall, one of the Inspectors of Mines, read his first paper on the subject before a meeting of the North of England Institute of Mining and Mechanical Engineers held in London.

During the year 1878 the present writer published a series of papers on "Coal-dust Explosions" in "Iron"; and while they were appearing Messrs. Marrecco and Morrison read their first paper on the subject.

Numerous societies of mining men, and individuals more or less connected with mining, now began to take an interest in the subject, and to make experiments with coal-dust. About this time, also, Commissions were appointed by the Governments of England (Royal Commission on Accidents in Mines 1879), France (Commission du Grisou), Prussia and Austria, to inquire into the causes of mining accidents, and amongst other things to investigate the probable influence of coal-dust in colliery explosions.

This sudden activity was no doubt quickened by the events of the ten years ending with 1880, during which the loss of life from explosions was twice as great as it had been during any previous decade. Taking into account only those explosions in which ten lives and upwards were lost, we find that there were thirty-five explosions, involving the lives of 2014 persons, of which 1411 were attributable to the second half of the decade.

In 1880 Prof. (now Sir Frederick) Abel, one of the English Commissioners, was instructed by the Home Secretary to investigate and make a special report upon the Seaham colliery explosion (September 8, 1880). During the course of these investigations Abel repeated our experiments of 1875-76 with a similar apparatus with practically the same results as far as coal-dust is concerned; but he claimed in addition to have discovered that any very finely divided incombustible dust would render a mixture of air with 3 or 4 per cent. of firedamp inflammable. His apparatus was not, however, provided with any special means of mixing the gas and air such as had been used in our own apparatus, of which it was otherwise a copy.

The German Commissioners erected and made experiments with an apparatus similar to one that we had described to the Royal Society in 1881, but on a somewhat larger scale, and they obtained similar results. Unfortunately, however, they passed away from the main question, viz. whether an explosion that *has taken place* in a dry and dusty mine under the circumstances that would have been formerly described as mysterious, can be attributed to the influence of the coal-dust in the supposed absence of firedamp?

The French Commissioners arrived at conclusions adverse to the coal-dust theory. They made no special experiments with coal-dust on an important scale and they did not, so far as can be gathered from their reports, examine the workings of any mine immediately after an explosion.

The Austrian Commissioners arrived at the conclusion which we had previously stated in this country, namely, that the relative fineness of a dust has far more to do with its relative inflammability than its chemical composition.

The English Commissioners expressed an oracular opinion. They denied on the one hand that coal-dust could be the principal agent in great colliery explosions, for, "If that were the case," said they, "an explosion would happen every day, nay every hour." But, on the other hand, they endeavoured to point out that coal-dust may be an element of the gravest danger under certain circumstances which they proceeded to define in a very precise manner. The Act of 1887 embodies their recommendations regarding safety lamps, explosives, and coal-dust.
